December 28th.—The incontinence of urine and fæces has ceased. Pulse continues strong, regular, and full; dyspnœa has disappeared, and the œdema entirely.

December 31st.—Patient shows signs of relapse; the urine and bowel discharges again becoming involuntary. Ordered tr. belladonna, gtt. xv.; ext. ergotæ, ʒ j., t. i. d.; with tr. digitalis, tr. strophanthus, āā ♏iij.; sol. nitro-glycer., ♏ij., every three hours.

January 5th.—Condition the same; to increase the digitalis and strophanthus to ♏v. each.

January 10th.—No change.

January 15th.—Patient much the same.

January 21st.—Died; was conscious to the last.

Autopsy.—Heart hypertrophied and dilated, with fatty degeneration; no valvular lesions. Liver smaller than normal, with fatty cirrhosis. Kidneys were small, granular, white, and fatty; the disease more advanced in the left than in the right kidney.

CASE V. *Cardiac hypertrophy, with dilatation; chronic bronchitis and rheumatism; anasarca, with extreme dyspnœa and cyanosis; marked improvement.*—Catharine F——, Irish, aged fifty, single, housemaid; admitted December 28, 1887. For the past year the patient has been very short of breath on exertion, accompanied by palpitation, blueness of face, and coldness of extremities; unable to lie down, and consequent insomnia. For the past five weeks the palpitation, dyspnœa, and cyanosis have increased; the feet swelled, and the dropsy extended up the groins. She gives a history of repeated attacks of rheumatism; the first, six years ago, when she was confined to bed with inflammation of ankles and knees for three months. Family history negative, no venereal. On admission the patient was livid in countenance and in extremities. Her dyspnœa was so intense that she could not articulate properly. Extremities cold and œdematous; the anasarca extends to the waist. No pulse can be felt. Heart hypertrophied and dilated quite extensively; sounds very feeble; asystolism, with indistinct mitral murmur; rate of heart-beats, 176; very irregular. Ordered a purge of pulv. jalapæ co. and calomel; then tr. digitalis, tr. strophanthus, āā ♏iij., sol. nitro-glycerine, ♏ij., every three hours. Urine, in twenty-four hours, ℥ xii., dark; sp. gr., 1.020; no albumen.

December 29th.—Pulse can be counted fairly well, 140; more regular. Urine, ℥ xxviii.; sp. gr., 1.021.

December 31st.—Pulse more regular, 109; much fuller and stronger. Urine, ℥ xxxii.; sp. gr., 1.018; dyspnœa much less; cyanosis disappeared; œdema rapidly decreasing.

January 4th.—Urine, xlv.; sp. gr., 1.023; pulse regular and not intermittent, except on exertion or excitement; can lie down without discomfort.

January 10th.—Up and about; no dyspnœa nor œdema; passing, on an average, ℥ xxxv. daily.

January 24th.—Is doing well; up most of the day; still has some œdema about the ankles; pulse regular and fairly full. Continue treatment.

CASE VI. *Cardiac dilatation, with anasarca; rapid action of the heart; improvement.*—Patrick K——, aged fifty, Irish, married, laborer; admitted December 30, 1887. Patient was in hospital last winter with attack of cardiac palpitation, cyanosis, dyspnœa, and œdema of extremities; was relieved and discharged. Patient now states that he did comparatively well, until three months ago, when he had an attack of pain in the region of the heart, accompanied by palpitation, dyspnœa, vertigo, blueness of lips and ears, and slight œdema of ankles. He had also an occasional dry, hacking cough, with watery expectoration. He was a moderate drinker. Had chancre three years ago; no secondary. Has been vomiting for the last two weeks; has taken no food, not even milk and lime-water. Has passed sufficient urine, and his bowels moved every other day, unless he took a cathartic, which was very seldom. No family history of cardiac or pulmonary disease. Had rheumatism six years ago; no cardiac symptoms. On admission, well-developed and well-nourished man. Has extreme dyspnœa; breathing much accelerated, 50 to the minute; orthopnœa; extreme cyanosis of lips and face. Cardiac action very much labored and weak; heart-sounds indistinct; asystolism; heart irregular in rhythm and force; pulse imperceptible. Rate of heart 150 to each minute. Œdema of feet and abdominal cellular tissue, pitting slightly on pressure. Fluid in both pleural cavities. Heart much dilated, with diffused and feeble apex-beat. Slight mitral regurgitation and double aortic murmurs. Urine was sufficient in quantity the first day of admittance, ℥ xxx., and dark red in color, with sp. gr. of 1.020; contained no albumen. Ordered a purge of pulv. jalapæ co. and calomel; then tr. strophanthus and tr. digitalis, āā ♏iij., every three hours; no nitro-glycerine given on account of rapid heart-action.

January 2d.—Heart-action much stronger, as shown by pulse. Pulse, 120, stronger, fuller, and very perceptible at both wrists; still irregular in force and rhythm, but less so than formerly; dyspnœa and cyanosis less. He rests in bed, on a general diet. Urine, ℥ xl. daily; dark; sp. gr., 1.020; acid.

January 4th.—Heart beats at the rate of 90 to the minute, full and strong, but still markedly irregular in force and rhythm. Urine, ℥ xlviii.; sp. gr., 1.024. Treatment continued.

January 7th.—Pulse strong and full, compressible, but still irregular and intermittent, 72 to minute; no dyspnœa while lying in bed. Urine, same in quality; amount, ℥ lxv. daily. Ordered, add sol. nitro-glycerine, ♏ij., to the tr. strophanthus and digitalis.

January 12th.—Improving gradually; is very comfortable; no dyspnœa or cyanosis; pulse, 75 to minute; still irregular and intermittent, but much improved in strength and calibre; œdema entirely gone. Nitro-glycerine does not cause dyspnœa, nor increased action of the heart.

January 17th.—No dyspnœa. Is up and about ward. Urine, sp. gr., 1.020; amber, acid; no albumen.

January 24th.—Pulse still irregular and intermittent. Ordered tr. digitalis and tr. strophanthus, āā ♏iv.; sol. nitro-glycerine, ♏ij. Patient feels quite comfortable.

CASE VII. *Cardiac hypertrophy and dilatation; bronchitis; general anasarca; improvement.*—Jane C——, aged fifty, Irish, widow, dressmaker; admitted January 12, 1888. Four weeks ago patient noticed that her feet were much swollen, and that her urine was scanty and dark colored, and her appetite completely failed. At the same time her heart troubled her more than ever. She had suffered for several months with vague pain and palpitation in region of heart, with sense of suffocation and shortness of breath. She had symptoms of a chronic bronchitis for a long time previously. Five years before, had a subacute attack of rheumatism. Gives a history of syphilis and hard drinking.

On admission, patient is dropsical all over body, with ulcers on her legs; extreme orthopnœa; cyanosis extreme; pulse imperceptible. On examination, heart greatly hypertrophied and dilated; action extremely rapid and irregular; double murmur at base; single systolic murmur at apex; heart-beats, 195; respiration, 50. Urine, the first twenty-four hours, ℥ xvi., dark; albumen, twenty per cent.; urates; sp. gr., 1.028. Ordered tr. digitalis and tr. strophanthus, āā ♏iv.; spts. ammonia arom., ʒ j., every three hours.

January 14th.—Cyanosis disappeared; œdema less. Heart more regular, and intermits only every 30 beats; rate, 110; pulse can now be distinctly felt and is quite regular.

Patient can lie down in bed. Urine, ℥ xxii. in twenty-four hours; light in color; albumen, fifteen per cent.; sp. gr. 1.026. Part of urine is passed involuntarily.

January 16th.—Heart is quite regular and much stronger; rate, 85; œdema has entirely disappeared from body, but not from legs. Urine, ℥ xxviii. in twenty-four hours; albumen, ten per cent.; all passed voluntarily.

January 28th.—Gangrene of the ulcers on the legs set in and patient transferred to Erysipelas Pavilion. Temperature, 102.8°.

Remarks.—The only service that can be expected of neurotics is that they should assist us in emergencies of functional derangements, as they can exert no permanent effect on organic changes in any disease. In all the foregoing cases, not only did such textural damage exist, but no more unfavorable class of patients could be selected, for constitutions broken down by drunkenness, syphilis, and bad modes of living in general. Moreover, not one of them was below forty-five, the average age being about fifty-two. In each case the emergency was liability to total cardiac failure, following upon chronic circulatory embarrassment, leading to water-logging of the body and death from the filling of the lungs. This particular danger was markedly relieved in each case by the combination of these cardiac neurotics, except in Case III., where no effect on the cardiac failure could be produced. In him, however, the heart seemed to be hopelessly fettered by extensive pericardial adhesions from any approach toward contracting to normal dimensions. In Case IV., the relief from suffocation and the disappearance of the anasarca were, at first, as marked as in any of the others, but, besides the cardiac changes, there was advanced Bright's disease with cirrhosis of the liver, and therefore, ere long, the neurotics began to fail, as sooner or later they always will. It may be objected that the favorable results were due to the digitalis administered, as similar effects, in cases of cardiac dilatation, can be cited from hospital patients, when treated by digitalis alone, along with rest in bed and the withholding of alcohol; but in Case I. the digitalis was given for only two days, in the fatal Case III. its addition did not improve matters, and in Case IV it was not given during the improvement, and not till the fatal relapse began. Moreover, the average dose of only three to four minims of the tincture of digitalis is another proof that not much can be ascribed to it alone. It is interesting to observe that in Case VI. the nitro-glycerine was withheld at first, because of the extremely rapid action of the heart, with apparent paralysis of the superficial vessels; but, on giving it afterward, instead of increasing this symptom, it appeared, if anything, to diminish it, and seemed much to increase the patient's comfort on its addition to the other cardiac remedies.

As the most common indication, however, for heart-stimulants occurs in the prostrations of acute diseases, I proceed now to cite examples of the use of the combination of cardiac neurotics in such cases.

CASE VIII. *Contracted pelvis; pregnancy, labor; Cæsarean section, followed by peritonitis, bronchitis, double catarrhal pneumonia; bed-sores; abscesses of the thighs; thrombosis of femoral vein; puerperal mania and pelvic abscess; recovery.*—Elizabeth L——, aged twenty-six, English, married; admitted November 21, 1887, in the Emergency Pavilion of the hospital, service of my friend Professor W. T. Lusk. Patient had been in labor five days, and, on admission, her pulse was 140, very weak and compressible; dyspnœa, due to exhaustion; held nothing on stomach for a week before entrance. Examination showed rachitic pelvis, conjugate diameter, 2½ inches, thus necessitating Cæsarean section, which was done by Professor Lusk, November 21, 1887, 2 P.M. After an uneventful recovery from the immediate effects of the operation, she first developed bronchitis on November 28th, which caused a broncho-pneumonia at base of right lung.

November 28th.—Temperature, 102.8°; pulse, 140; respiration, 40. Has had Magendie hypodermically, ♏vij., about every four hours, for restlessness and pain. Her cough caused her abdominal wound to gape, so that it had to be controlled by morphine; this, however, seemed to cause the mucus to gravitate to base of lungs. 4 P.M.: Tongue dry and brown; slight nausea and hiccough. Has had brandy, ℥ ss., q. three hours, and ammon. carb., gr. v., q. three hours. Oxygen inhalation for dyspnœa.

November 29th.—Temperature, 102°; pulse, 136; respiration, 40. Treatment kept up. Patient's condition the same, although tongue more moist. For temperature, cold fever coil was applied to abdomen.

November 30th. — Patient delirious. Temperature, 100.8°; pulse, 137; respiration, 35. Oxygen, carbonate of ammonia, and brandy, ℥ ss., q. three hours, kept up.

December 1st.—Very restless; nutritive enemata not retained. Temperature, 102.2°; pulse, 131, and feeble; respiration, 32, and dyspnœic. Morphine still kept up to the extent of ♏xxx. in the twenty-four hours.

December 4th.—Temperature, 103°; pulse, 138; respiration, 45. Pulse very weak and compressible. Is very restless, and delirious. Tongue dry and brown and sordes on the teeth and lips. Examination revealed pneumonia on left side. Antifebrin, gr. v., for temperature. Hypodermic of tr. digitalis, ♏v., every three hours, and carbonate of ammonia every three hours. 5 P.M.: Temperature, 104.4°; pulse, 142, dicrotic and irregular. Patient sinking rapidly; extreme dyspnœa and œdema of both lungs; delirious and restless. 6 P.M.: Cupped anteriorly. Pulse, 170, and almost imperceptible.

At this stage in the history of the case, I was asked to prescribe for the patient, and I recommended the combination of two minims each of tr. strophanthus and one per cent. solution of nitro-glycerin, to be given, hypodermatically, every hour, and pushed according to the urgency of the symptoms; while the oxygen inhalation should be given for fifteen minutes in every hour.

December 5th, 1 A.M.—Temperature, 103.4°; pulse, 138, much better than before strophanthus was given. It was a little fuller, stronger, and more regular. 9 A.M.: Pulse stronger, regular, and compressible, and 138 to the minute. Œdema of lungs has disappeared, and general condition of patient hopeful. The hypodermics of tr. strophanthus and nitro-glycerine were kept up for two days, after which these medicines were given by the mouth. She had, later, several attacks of dyspnœa and cyanosis, which were relieved by hypodermics of tr. digitalis and tr. strophanthus, āā ♏iv. The local irritation of the strophanthus, however, in some cases gave rise to abscesses, which led to its discontinuance by that method. The urine increased from ℥ xviij. to ℥ xxiv., in the first twenty-four hours, during administration of strophanthus and nitro-glycerine.

December 11th.—Large, burrowing abscess has developed on each thigh.

December 14th.—Thrombosis set in of left femoral vein, shown by pain localized in its course and by œdema of leg. Patient delirious, with pulse 150. Treatment: Leg elevated. Tr. of iodine applied to region of vein.

December 16th.—Attacks of dyspnœa and cyanosis very frequently occur. Pulse rapid and irregular.

December 18th.—Swelling of femoral diminishing and œdema also going down. Thrombi apparently broken up and softening, as discovered by palpation. Patient is maniacal at night; has delusions and hallucinations. Temperature, 99.8°; pulse, 130; respiration, 27. Has beginning of puerperal mania. Râles still heard in chest, accompanied by cough.

December 21st.—Mania continues, and of the most active character, and accompanied by rapid pulse and cold, clammy sweats. No temperature.

December 25th.—Still maniacal at night, with formation of a bed-sore.

December 27th.—An exudation felt between uterus and rectum, painful on pressure. Temperature, 99.8°; pulse, 140.

December 29th.—Sudden discharge of fetid pus from vagina, accompanied by some pain and great anxiety on the part of the patient. On palpation, mass was found to have disappeared from its position, and on opening, discovered in roof of vagina, showing spontaneous rupture. Temperature, 102.4°; pulse, 140; respiration, 30. Patient very restless and excited.

January 2d.—Patient rapidly improving; is still very weak, but is taking plenty of nourishment.

February 14th.—Discharged, cured.

CASE IX. *Double lobar pneumonia.*—John H——, aged twenty-eight, Irish, married, bricklayer; admitted November 29, 1887. Two days ago patient, while working in the rain, caught a chill which lasted nearly two hours, followed by a slight feverish condition, and the next day he had a cough, with no expectoration. The next evening, had muco-purulent sputum streaked with rusty blood. Had severe dyspnœa, and felt very sick. Had been a drinking man for five years and, the last two months, has been frequently intoxicated.

On admission, temperature, 103½°; pulse, 150; respiration, 44. Dyspnœa; cough, with tenacious, rusty sputa. On examination, middle of left lung consolidated. Ordered ammon. carb., gr. vj., q. two hours; whiskey, ℥ ss., q. two hours.

November 30th.—Pneumonic consolidation now in entire left lung; œdema of legs. Ordered ammon. carb., gr. v., q. two hours; whiskey, ℥ j., q. one hour. Cupped twice over left lung and apex of right, where crepitant râles could be heard. Pulse, 160; respiration, 39; temperature, 101⅘°.

November 31st.—Œdema of both lungs; signs of pneumonia in both lungs; sweating profusely. Ordered tr. strophanthus, ♏iv.; sol. nitro-glycerine, ♏ij., q. two hours. Whiskey stopped. Pulse stronger and more regular, 135.

December 2d.—Œdema has disappeared; also the profuse perspiration. Pulse stronger and fuller, 110 to minute. Ordered tr. strophanthus, ♏v.; sol. nitro-glycerine, ♏ij., three times a day.

December 6th.—Subcrepitant râles and other signs of resolution present. Ordered spts. ether nitr., ʒ ij.; potass. acet., gr. x.

December 10th.—Broncho-vesicular respiration. Very few râles. Ordered tonics.

December 13th.—Up and about ward.

December 20th.—Discharged, cured.

CASE X. *Double lobar pneumonia.*—Christian H——, aged thirty-eight, German, married, cabinet-maker; admitted November 24, 1887. Two days before admission patient had a severe chill followed by a high fever and cough. Expectoration at first frothy and mucous, later rusty and tenacious. Had been drinking considerable beer for a week past, and was under its influence when the chill attacked him—after exposure. On examination, apices of both lungs consolidated; also right middle lobe, with pure bronchial breathing and a few crepitating râles. Œdema of the right lung. Patient was delirious on entrance, with pulse very irregular and intermittent, rate, 165; respiration, 42. Dyspnœa; no cyanosis. Temperature, 102°. Ordered tr. digitalis. gtt. v.; whiskey, ℥ j.; sol. atropiæ, gr. $\frac{1}{120}$, three times daily. Cups to chest at 7 P.M.

November 26th.—Pulse rapid and irregular and intermittent. Œdema of lungs has disappeared. Ordered tr. strophanthus, gtt. iv.; tr. digitalis, gtt. iv.; sol. nitro-glycerine, ♏ij., three times daily.

November 28th.—Subcrepitant râles in both lungs. Pulse regular and strong, 110 to the minute; temperature, 100°. Ordered quiniæ, gr. v.; spts. ætheris co., ʒ j.; whiskey, ℥ ss., three times daily.

December 2d.—Resolution rapidly going on. Without digitalis and nitro-glycerine pulse gets weak and rapid, with a tendency to irregularity. Ordered tr. digitalis, gtt. v.; nitro-glycerine, gtt. ij., three times daily; ammon. carb., gr. v., q. three hours.

December 6th.—Up and about ward. Resolution almost completed. Ordered tonics.

December 11th.—Discharged, cured.

CASE XI. *Double pneumonia; phthisis.*—Susan G——, aged thirty-two, American, widow, domestic; admitted December 19, 1887.

Three weeks ago patient was taken sick with severe headache, dizziness, and high fever; had a cough and watery expectoration; had no chill; had a sweating spell four days afterward at night, and lost her voice until she could hardly speak above a whisper; said she was out of her head at night for a week before entrance; no hæmoptysis; has had a cough for five months, with muco-purulent expectoration; slight loss of flesh; said she had pneumonia six years ago, and recovered perfectly. Family history negative as regards lung trouble. On admission, patient has temperature of 103°; pulse, 138, full and compressible, but not much force to it; respiration, 40, and dyspnœic; tongue dry, brown, and fissured, with sordes on the teeth; voice husky, semi-delirious. On examination, pure bronchial breathing and other signs of pneumonia on the right side, posteriorly upper, and middle lobes, with few crepitating râles. Anteriorly, signs of small cavity, right apex. Ordered tr. digitalis, ♏v.; sol. nitro-glycerine, ♏ij.; ammon. carb., gr. v., every three hours.

December 20th.—Pulse, 120, full and strong; respirations, 35; temperature, 102.5°; expectoration scanty; lungs in same condition.

December 21st.—Pulse, 110; respiration, 28; temperature, 101°. Feeling more comfortable, only a little dyspnœa. Urine has increased five ounces over yesterday. Ordered the same.

December 22d.—Sudden sharp pain on left side in region of nipple, increased on inspiration. Temperature, 103°; pulse, 130; respiration, 29, and dyspnœic. On auscultation, signs of pleurisy. with beginning pneumonia at base of left lung. To continue the tr. digitalis, ♏v.; sol. nitroglyc., ♏ij.; ammon. carb., gr. v., every three hours. Poultices.

December 24th.—Temperature normal; no râles in chest. Pure bronchial breathing posteriorly on right side; broncho-vesicular and exaggerated on the left, posteriorly, above, with diminished resonance below (fluid suspected).

December 27th.—Patient rapidly improving; blister at right apex posteriorly, 4 × 4 inches.

December 28th.—No changes, patient up and about.

January 6th.—Discharged at own request. Broncho-vesicular respiration on the right, and amphoric at apex anteriorly.

Remarks.—Professor Lusk's most interesting case I cite simply as an example of the power of the combination of these cardiac neurotics at particular junctures. The patient seemed to be saved from fatal exhaustion by their administration, when every other resource had proved inadequate to rally her sinking powers. I have seen similar good results from them in cases of pneumonia in my consultation practice, when I have been called after urgent symptoms have set in, and then found them manifest their superiority to alcoholic stimulation in these conditions.

ALCOHOL AND RACE.—While alcohol does not seem to have produced any racial deterioration in white races, or rather in the Indo-Germanic family, it acts differently upon Asiatic and dark races. Says a writer in *The Contemporary Review,* alcohol in any quantity seems to set most Asiatics—the Jews are an exception—on fire, to produce an irresistible craving for more, and to compel them to go on drinking until they are sunk in a stupor of intoxication. They appear to delight but little in the exhilaration produced by partial inebriety, and to seek always a total release from consciousness and its oppressions. The condition of "dead drunkenness," which few even of drinking northerners enjoy, is to them delightful. "I not drinkee for drinkee," said the Madras man; "I drinkee for drunkee." Alcohol is therefore to such races an intolerable evil, and its consumption by them is in the eyes of all strict moralists an immorality.

DISEASES OF, AND OPERATIONS ON, THE TESTICLES.[1]

By EDWARD BORCK, A.M., M.D.,

ST. LOUIS, MO.

Mr. President and Gentlemen: My paper is not an elaborate treatise upon any single disease or operation upon the testicles. I merely wish to give you some general remarks, based upon personal experience and observation. I will only give my own opinions, and offer them for the purpose of soliciting, if time permits, a discussion upon this interesting topic, and call the attention of the profession to this subject.

Permit a few preliminary remarks. "The diseases of women," a term which we use to designate the diseases of the ovaries, uterus, and appendages, have received of late very much attention and study by the medical profession. We are half inclined to think that the progress in the treatment of these afflictions has been so wonderful, the cures so remarkable, that, if a new generation would grow up, the present generation before long ought not to suffer any more, for they will all be cured in some way or other. According to the latest information received, it seems that nine women out of ten have some tilting up or sinking down of their organs. The openings of the uterus in some cases are too narrow, in some too wide, and each case needs treatment of special skill! Now, I do not claim to be a specialist of any sort—only a modest general surgeon, and as such I am called upon to treat and operate upon the female generative organs, as well as upon other organs of the human body; and those of you who are acquainted with me know that I have given some attention to the study of these diseases, and have performed a few of the various operations upon the female sexual organs. These cases have taught me some things, and have set me to thinking, and the question now comes to my mind, "Why have women, or, rather, their sexual apparatus, received so much attention by medical and other men?" Is it not because we all love these dear, tender creatures so much—so much so that we think of little else, and are wholly absorbed in the welfare of her reproductive organs, and thus the great affection that we carry in our bosom and display for the opposite sex causes us to see everything pertaining to them through a magnifying-glass? Or has it come to this, that it is an actual fact that there are no sound and healthy women to be found upon mother earth any more, and none more to be born hereafter? Everyone may answer these questions for himself.

Now, the other side. We hear little or nothing said about the diseases of the testicles; very little, if anything, appears in the journals on this subject. No new works have lately been written upon the testicles. Are the ovaries in women not considered the counterpart of the testicles in men? The former organs have received from the profession the kindest attention possible; the latter, comparatively speaking, none. The question now comes up: "Why have the ailments of the testicles been so neglected? Do they need no attention? Is it true that every man is blessed with sound and healthy testicles? Is man endowed with generative organs entirely free from imperfections and liability to disease?" I do not believe that such is the case. Or is the medical profession to be blamed for not investigating the diseases of man's reproductive organs? If only one man out of ten should be affected with some kind of disease of the testicles, and I believe there are, what a rich field for study and inquiry is offered here for a specialist (testicologist).

Let us view, or glance over, a few of the diseases of the testicles and their appendages. First of all, there may be mentioned the congenital deficiencies and imperfections of these organs. And first, I mention supernumerary testis. Of this I have only seen one case in my practice. In this case a third perfect testicle was found, in a young man, twenty-four years of age, upon whom I operated for strangulated hernia. I have seen many supposed cases of supernumerary testis, but they all proved to be other bodies, such as fatty tumors, etc.

Second: Atrophy of the testicles. Arrest of development and wasting. Deposition of fat, elephantiasis, inflammation.

Third: Injuries of the testicles. Contusion, accidental puncture, and incised wound. (Since these latter heal up almost without any trouble, why, then, be afraid to incise a testicle if some disease indicates the need of it?)

Fourth: Acute, chronic, congenital, and encysted hydrocele.

Fifth: Hæmatocele.

Sixth: Orchitis. Tubercular disease. Cancer.

Seventh: Fibrous transformation and ossific deposits.

Eighth: Nervous affection, sympathetic and functional disorder. (These seem to me, in particular, to be very interesting studies.)

Ninth: Diseases of the testicles produced by injury to the head and spine.

The real causes, as well as the remote sequels, of the diseases of the testicle are very often overlooked.

I cannot go into detail of any of these diseases mentioned; time does not permit, nor is it the object of this paper. A few cases in point, to make clear the idea I wish to convey:

Case I.—Mrs. ——, a healthy, handsome young woman, marries; her husband is apparently well, but they have no children after four years of trial. The husband wants a baby, and, like other selfish men, wants by all means to have a boy-baby; he thinks the wife is at fault, of course. The family physician exhausted all his ingenuity, and his stock of prescriptions have all been tried in vain, but still no baby has come to bless this household with its smiles. Next, the case is referred to the gynecologist; surely he can find out what is the matter, and give relief. He discovered at once a little tilting of the womb backward; not very much, it is true, but he thought it was at least one-sixtieth of an inch out of the way, and there was, in addition, some abrasion of the cervix. Now the trouble is discovered why the family has no baby; so pessaries are introduced; iodine is applied locally to the neck of the womb for months; a small basketful of medicine has been purchased, from time to time. Every time the local applications were made to the womb, madam was assured by the gynecologist that she was getting better, and it would not be long to wait for the baby (special skill!). But madam herself did not think so. In her opinion she was getting worse all the time. One thing is certain, the baby did not come. At last her mind wandered, she became emaciated and despondent, and the case was taken from the gynecologist, and went into the hands of a first-class neurologist. He at once diagnosed the whole trouble. He very promptly decided that it was not the womb that was at fault—it was the nervous system; and, sure enough, he is right, for by this time it was the nervous system. Next in order come all the nerve-tonics, sea-bathing, travel, etc.; they did no good. Everything was done that could be thought of; even artificial fecundation was tried. The woman submitted to all this patiently, and with a heroism that was astonishing. But it was all to no purpose; the poor woman was now almost insane, and still there was no baby. Having failed of success, the neurologist now goes for his predecessor, the gynecologist, and shows how ignorant he was in his profession, and how lacking he was in skill. Remember, the first man sees everything through, and with the help of, the microscope; the second sees through, and with the help of, the speculum. However, neither of these gentlemen have discovered the true cause of all this trouble, nor have they pursued the correct treatment in this case. Last of all, this case was placed in my hands. Every practitioner is often called upon to explain the cause of barrenness, and to treat and cure it; but, very often, I am sorry to say, he is called upon to prevent pregnancy, or to cure (kill) pregnancy when already present. The latter is the most disgusting thing in all female practice. After examining this patient carefully, I found the gynecologist was right in his diagnosis—the womb was just one-sixtieth of an inch out of the way, and there was a little irritation of the uterus.

---

[1] Read at the Thirty-first Annual Meeting of the Medical Association of the State of Missouri, at Kansas City, Mo., April 18, 1888.

But was this the cause of the sterility? Not by a long way. I know of many a womb that deviates a little from the imaginary natural line, and they become pregnant all the same, and more than once, too. We find plenty of men with crooked noses, but they smell straight. Why could not a uterus with a little crook in it be impregnated? In fact, it is well known that the best pessary for a little prolapsus of the womb, if the lady is married, is impregnation, for it brings the womb up, and keeps it in place. Let us go back to our patient. She exclaimed: "Oh, doctor, if I only could become pregnant once and have a baby—a boy-baby—I think I would get well, and my husband would be satisfied." I consoled her with the hope that she would get well in time, dismissed her for the present, and asked her to send me her husband. Upon inquiry of him, he stated to me that the act of coitus, in his opinion, was not perfect; "too soon, or often nothing came at all," as he expressed it. He said that he had a peculiar feeling all the time in his testes—often had pollutions without erections. I found that he was predisposed to fatty degeneration of the heart; had fatty depositions in his scrotum and testicles. Upon examination of the semen, I found he had fatty degeneration of the spermatozoa. I advised separation for a time from the wife. I now turned my attention, not to the wife but to the treatment of the husband, and, I am happy to say, in time he recovered. In the meantime, having gained the confidence of my lady-patient, and having assured her that the gynecologist corrected all her troubles in the most skilful manner, and that, without doubt, the neurologist had improved her nervous system in a remarkable degree, and if she would only continue his medicine she would in time obtain the full benefit of his advice in that direction, and that she would in due time be ready for a baby. However, I gently informed her that her husband was also somewhat at fault, which in time would also be remedied, and the baby would surely appear. From that moment the lady improved, became more cheerful and once more hopeful, and, on the return of her husband from abroad, after a six months' separation, she was well, and he was apparently well, and she became *enceinte* in a short time afterward, and happiness once more prevailed, and a boy-baby was born to the exultant pair.

CASE II.—In this case the wife was treated for sterility without any benefit. I found the fault with the husband; his penis was of a very small size. He informed me that the organ was growing smaller all the time. I found he had a large cyst of the left testicle, which prevented the proper introduction of the penis into the vagina; he had this cyst before he was married, five years ago; lately the cyst had grown larger. None of the many male doctors for the treatment of female diseases who had treated the wife for barrenness had ever inquired into the condition of the husband's genital organs. To be brief, I removed the cyst, the penis became more of a natural size, and the wife presented him in due time with not one, but with a pair of babies.

CASE III.—The wife was unsuccessfully treated for sterility. The fault with the husband again, and though he was the son of a physician, and had congenital phimosis, he informed me that he never did nor could enjoy the act of coitus. Circumcision relieved the man of his ailment, and the result was a female baby.

CASE IV.—Reflex nervous affections produced by disease of the testicles. A merchant, aged about forty, married, with a happy family around him, doing a good business. He became sleepless, languid, his mind wandering, hypochondriac, ready to commit suicide; he was under the care of a good physician and a skilful neurologist for a length of time. Cause of the trouble attributed to business. Quitting the business and turning to pleasure alone gave him temporary relief. As soon as he returned to his family and resumed business, there was the old story again. He was sent to a private retreat, but with only temporary benefit; returning home, the old story. When this man consulted me, and his wife informed me of all the previous circumstances, I told them I was not a specialist, nor a neurologist, nor a gynecologist, nor even did I practise medicine—I was only a general surgeon; but they insisted upon having my advice, as they had been recommended to me. Now I began to examine him with surgical eyes. I inquired whether he had ever received any injury upon the head or spine, etc. All these questions were answered in the negative. "Well," said I, "step into the other room," which he did. "Now undress, please." He began to pull off his coat, vest, shirt. "Keep on," said I; "I want it all off—undershirt, pants, drawers—everything; I wish to see you naked." "I hate that," was the gentleman's exclamation. "Well," said I, "I am glad that man possesses modesty as well as woman; but I cannot do anything for you, nor give my opinion, unless you strip naked." "Well, doctor," said the patient, with some embarrassment, "I have something the matter with my privates." "Oh, please, let me look at it." With a little hesitation he produced a very large hypertrophied left testicle, and informed me that some years ago he had epididymitis. Here, at last, was brought out the cause of all the man's brain-trouble in a bag. I asked him, "Did you not tell your previous doctors of this complaint?" "No, I did not like to." "Did they not examine you? Did none of them inquire into the state of your testicles? Did not the neurologist?" "No, sir." A positive "no" was the answer. It is hardly necessary for me to say that I advised the removal of the diseased testicle, assuring him and his wife that the loss of that one testicle would not unman him, as there was a healthy one remaining to perform all the functions. After a great deal of hesitation on his part, and a great deal of persuasion on the part of the wife, he consented. All nervous trouble soon disappeared after the removal of the diseased testicle; peace, tranquillity, and prosperity once more returned, his business once more prospered, and this was followed by an erection of a large new store, and, best of all, he soon had an addition made to his family.

I could give more and similar cases. These are sufficient for illustration.

A few words in regard to neuralgic pains of the ovaries and the testicles; both sexes suffer from the above. In the case of a woman, where all known means for the relief of pain have been tried and have failed, and the removal of the offending ovary or ovaries being advised, she will readily and cheerfully consent. In the case of a man, under the same conditions, he is not willing to give up one testicle, far less both; he prefers to suffer the most excruciating pain, until at last he lands at the insane asylum. Neither is the removal of such a painful organ advised by physicians, or, if proposed, it is done reluctantly. Why? Can anyone give a definite answer?

The removal of a testicle, or any other operation upon their appendages, is not nearly so dangerous as the removal of the ovaries, or any other operation upon the female reproductive organ.

The operation for varicocele I now prefer is to cut down upon it, under strict antiseptic precautions, ligate the veins above and below, excise the distended part, and close the wound.

In conclusion, let me admit that I am a strong advocate for specialties, special studies, and believe in specialists; but I do not believe that it is correct for every new graduate to rush off to Europe at once, to study a certain specialty for three months, then return and begin his special skilled practice, with one-sided ideas and but little practical experience. It takes more than this to make a specialist.

I hope that someone having had ten or fifteen years' large general practice will give the diseases of the testicles and the operation thereon his special attention and study, and adopt it as a specialty.

I thank you for your attention.

PTOMAÏNES.[1]

By J. C. OLIVER, M.D.,

CINCINNATI, O.

I HAVE prepared this paper with the object of presenting to this Society, in as condensed form as possible, the results obtained by the various workers in this domain of pathology, and hence make no claim for originality in the following remarks :

Ptomaines are described as poisonous alkaloids produced by the decomposition of proteids due to the action of bacteria upon these substances. A familiar example of this decomposition is the production of alcohol by the action of yeast fungus upon glucose. Lauder Brunton says : "The cardinal fact that results from all these researches is that albuminous, or, to speak more correctly, proteid, substances, which are themselves foods, may be split up so as to yield poisons. This decomposition is usually originated by various species of low organisms, and especially of bacilli ; but it may be effected by the digestive ferments of the healthy body. The poisons formed by the decomposition of proteid bodies, such as albumen, fibrine, and gelatine, vary not only according to the particular body which is decomposed, but to the particular organism or ferment which sets up decomposition, and according to the temperature at which it occurs and the length of time it continues. Some of the products of the decomposition of proteid bodies are poisonous, others are innocuous. Among the poisonous bodies we find various degrees of activity, some being but slightly poisonous, while others are most virulent. When these poisonous products are separated from each other, and isolated, they may remain unaltered for a length of time ; but, when mixed together, they are apt to undergo further decomposition and become inert."

My idea is to present, this evening, a review of the work that has been done in this department in regard to the isolation of particular ptomaïnes in certain diseases. From the very definition of these chemical products we shall look for them in those diseases where bacteria are known to play an important part.

It is not my intention to go into the chemistry that is involved in the elaboration any further than is necessary for a short and succinct review of this branch ; my principal object is to present, as concisely as possible, the pathological effects these alkaloids produce upon the human system.

The toxic effect of cadaveric fluids has been known for many years, and their toxic effect must be attributed to a chemical poison rather than to the introduction of micro-organisms. Dupré and Bence Jones made the first authentic discovery of ptomaïnes when they isolated what they termed animal chinoidine. The names of Selmi, Gautier, our countryman Vaughn, Brieger, and Neucki stand out prominently in this field of research.

The character of the ptomaïne produced is dependent upon the nature of the bacterium, the character of the food, and the length of time during which the process is active. In regard to the first factor, it is extremely probable that different species of bacteria elaborate different chemical substances, and that they must have certain pabulum, or else they are incapable of chemical action. The albuminoids are recognized as the substances most favorable for the production of ptomaïnes.

The essential phenomena of cellular life, vegetable or animal, are physico-chemical in their nature, and in the case of living beings the sources of vital power are of two kinds: They result either from molecular modifications brought about by means of oxygen, the organisms deriving their vitality in this way being anaerobic, and belonging for the most part to the lower order of ferments ; or they result from internal combustion—aerobic—resulting in the absorption of oxygen and elimination of carbonic anhydride, water, and urea. Bacterial anaerobic life, acting in cadaveric matters, gives rise to certain poisonous alkaloids named ptomaïnes.

It is definitely established that during the putrefaction of nitrogenous animal matter certain fixed or volatile bases are formed, presenting the closest resemblance to the vegetable alkaloids, as well in their physiological as in their chemical properties, although, for the most part, they exhibit simpler chemical formulæ. Gautier has also proved that alkaloids arise in the tissues, not only while undergoing bacterial decomposition, but also during their period of physiological activity. These latter products are known as leucomaïnes. Between ptomaïnes and leucomaïnes there exists the closest analogy, in fact, a certain number of alkaloids are common to both series. This close relationship would seem to indicate that the reactions of proteid materials undergoing destruction are analogous to the putrefactive phenomena induced by fermentation, and result from a decomposition of the same materials.

"About the year 1871 Selmi demonstrated the importance of ptomaïnes to forensic medicine, by his brilliant researches in a poison case, upsetting the expert testimony which tended to convict the accused. This was during the celebrated trial for the supposed murder by poison of the Italian General Gibbone, whose servant stood accused, on circumstantial evidence, of having administered to him the poison. Two prominent experts declared to have found delphinine in the intestines of the deceased. Selmi proved incontestably that the same reactions as produced by the experts for the prosecution would also result from a ptomaïne obtained by him in the usual manner from the alkaline fluids of the animal substances by extraction with ether. He showed, besides, that delphinine responded to many reactions which the substance derived from the deceased's body did not yield. Professors Ciaccia and Villa, of Bologna, demonstrated, over and above this, that the base obtained from the defunct's body did not coincide in physiological action with that of delphinine.

"This, of course, tended to revolutionize all dogmas in regard to poisoning by alkaloids, and the medico-legal proofs of their existence, especially as subsequently strychnine and morphine were found to be closely simulated in their reactions by those of certain ptomaïnes."

In another case in which death was supposed to have been caused by morphia, and the body exhumed twelve days after burial, the presence of morphia was said to have been demonstrated ; Selmi proved that the alkaloid which they claimed to be morphine was really a cadaveric alkaloid, which responded to chemical tests similar to those for morphine.

These investigations were soon confirmed by other observers, and the ptomaïnes are liable to upset the previous methods of chemico-legal research.

Another fact established by Selmi is, that the duration of decay has a very marked influence on the production of ptomaïnes, so that different bodies are generated at different times, and that all of them are unstable. The alkaloids formed early in the process of decomposition are more virulent than those formed later in the putrefaction.

For fear of prolonging my paper to too great a length—for this subject really embraces a very large part of the domain of pathology—I shall now devote the remainder of it to the consideration of special diseases, and the relations sustained by these animal alkaloids to the diseases in question.

Let us consider Asiatic cholera, and the problems it offers. In this connection I shall quote very largely from the writings of Brieger, and also from those of Koch. "The progress of modern medicine is due to the fact that it has become more scientific than it has ever been before. We now know that most diseases that affect man and animals are of bacterial origin, and that only a diminishing minority of the known diseases is due to external traumatic causes or disturbances of nutrition. It is now established undoubtedly that Asiatic cholera is due to the comma bacillus discovered by Robert Koch; but the pernicious influence which this unwelcome guest exerts upon the body of its host must rest, according to prevailing ideas, upon chemical changes. Koch himself, in his first publication on the subject,[1] expressed himself in the following words: 'The poison exerts its effect, in part, immediately, the epithelium, and in the worst cases the upper layers of the mucous membrane being killed; in part by its absorption and action upon the whole body, especially the circulatory organs, which suffer a kind of paralysis. The complex of symptoms of a true cholera attack, usually ascribed to a loss of water and the thickening of the blood, must be regarded as in reality due to poisoning, for they are occasionally seen when relatively small quantities of water are lost, and where the intestine, after death, is found to contain little fluid.' Koch obtained cultures of the comma bacillus which, when injected into mice, caused paralytic weakness of the hind legs, coldness of the head and limbs, delayed respiration, and death in a few days. V. Ermsugem[2] caused death and algidity in guinea-pigs by the injection of culture-fluid, from which the bacilli had been removed by a Chamberland filter, or destroyed by heating to 60° or 70° C. for half an hour. Attempts to isolate the active principle of cholera bacilli have not been very successful hitherto. Pouchet extracted by chloroform from cholera dejections, and, later on, from cultures, a toxine which soon killed frogs when used subcutaneously. Villiers obtained, by Stas' method, from the viscera of two cholera corpses, a liquid toxine of sharp odor, the hydrochlorate of which crystallized in long, fine needles. Nicati and Rietsch made similar experiments, producing a toxine which caused cramp and lowered the temperature.

---

[1] Read before the Cincinnati Medical Society.

"Klebs and Lange have lately obtained a crystallized toxine by mercuric and argentic chloride precipitations in fish-broth cultures of cholera vibriones, which caused convulsions and death in rabbits when injected in small quantity into the jugular vein. In one rabbit calcification of the epithelium of the convoluted tubes, and in some of the straight tubules, was found.[3] In the *Deutsche Med. Wochenschrift* of 1887, Nos. 15 and 22, Brieger calls attention to his having isolated a substance to which he gives the name of cholera-red. The author says that its importance lies in the fact that it is a derivate of indol, a substance present in every fetid putrefaction. In fact, indol itself is formed by cholera bacilli, if these are reared on an albuminous nutrition.

"Cholera-blue, discovered and thus designated by the same authority, is less frequent. It is produced by the action of concentrated sulphuric acid upon 'meat-broth-peptone-gelatine' cultures, and only when cholera-red also is present.

"In his investigations into the ptomaines and toxines of comma bacillus, Professor Brieger used pure cultivations, repeatedly supplied by Koch. The cultures were sterilized, filtered hot, evaporated down, and repeatedly extracted with alcohol; the latter was then precipitated by mercuric chloride. The precipitate was boiled in water, the solution decomposed by H_2S, evaporated down, and extracted with alcohol. This extract was then precipitated by picric acid, or picrate of soda, or gold-chloride, or platinum-chloride.

"Cadaverin was occasionally present in considerable quantity after only twenty-four hours' growth of the bacilli; older cultures yielded still more cadaverin, and a little putrescin. Cholin, the base of lecithin (a complex normal constituent of flesh), also increased with the age of the cultures, and reached its maximum in four weeks. Kreatin proved much more resistant to the bacilli; but a small portion was gradually converted to a 'toxine' named methyl-guanidin, $C_2H_7N_3$, a powerful poison, causing dyspnœa, muscular tremors, and general convulsions in mammalia. This convulsion denotes an oxidizing power in the cholera bacilli, for methyl-guanidin can be obtained from kreatinin only by an oxidation process.

"Specific toxines were also produced, but only in small quantities, and some time after the appearance of non-poisonous ptomaines. Cadaverin seems to exert a restrictive action upon this formation. The cultures were modified in various ways, but only very small quantities of a toxine which seemed to have the formula $C_3H_8N_2$ could be obtained. The formula given is only tentative. Proof was afforded of the presence of a second toxine, hitherto unknown, which caused algid symptoms in mice, sometimes with bloody diarrhœa. Thus these bacilli formed cadaverin, a large quantity of putrescin, and small quantities of toxines; and, moreover, evinced in so doing considerable chemical energy, which may account for the violent character of the symptoms of Asiatic cholera.

"Observers have noticed the decided spermatic odor attaching to rice-water stools, and this odor is very pronounced in cadaverin. Schuerlein, Grawitz, and Fehleisen, each ascribe violent inflammatory and necrotic properties to putrescin, not only locally (loss of intestinal epithelium) but generally, as even minute quantities prevent the coagulation of the blood. Methyl-guanidin and the second toxine, having the formula $C_4H_8O_2$ cause convulsions, the latter toxine causing also algidity and bloody stools. Thus the main symptoms of cholera, together with their violent onslaught, are apparently accounted for as the combined action of the products of the comma bacillus. It remains for the clinician to search for these products in the dejections of cholera patients, and in the viscera and blood after death; if success attend this search, appropriate therapeutical measures will suggest themselves." This account is taken from a translation by E. J. Edwards, M.D., of the article by Brieger "On the Tissue-change Products of the Cholera-bacillus."

Puerperal Fever.—Dr. L. Bourget, in an inaugural address, states that he has succeeded in isolating certain ptomaines from the urine of several women suffering with puerperal fever. Having studied these substances from a chemical and biological point of view, he has arrived at the following conclusions:

1st. In puerperal fever the urine contains some bases of a very toxic nature.

2d. The toxic principles seem to attain their greatest development during the acute period of the disease. Their quantity diminishes with decrease of morbid phenomena.

3d. The chemical bodies in question produce in animals (frogs and guinea-pigs) exactly the same disturbances as are brought about by certain poisonous ptomaines.

4th. Various organs of a woman who had died from puerperal fever were also found to contain some toxic substances which, in their biological effects, closely resembled the toxic bases obtained from the urine.

5th. All those extractive products found in the urine gave all the general reactions of vegetable alkaloids and ptomaines.

6th. In a chemical analysis for medico-legal purposes they may be mistaken for vegetable alkaloids, or, at least, may interfere with the characteristic reactions of the latter.

7th. Such grave mistakes can be avoided by carefully purifying the examined material after Stas-Otto's method (*Brit. Med. Journal*).

I have presented the investigations of the chemical causation of cholera and puerperal fever at some length; but, for fear of prolonging my paper to too great length, I shall refrain from taking up, *in extenso*, the observations in typhoid fever, uræmia, tetanus, biliousness, septicæmia, rheumatism, summer diarrhœa of infants, milk- and cheese-poisoning, sausage- and mushroom-poisoning, and numerous other affections.

[3] Klebs: Allgemeine Pathologie, p. 374.

Ptomaïnes have undoubtedly opened up a field of research which, to say the least, promises a rational explanation of many of the phenomena met with in various diseases. These phenomena have never, hitherto, received any satisfactory or intelligent explanation. Take, for instance, the symptoms of typhoid fever, and we are compelled to confess that the usually given causes, such as the height of the fever, the lack of nervous control, etc., have been at the best but suggestions, and really no explanation at all; for we find cases where these supposed exciting causes are entirely absent; therefore I think we are forced to the conclusion that these symptoms are caused by the effect of poisons generated and elaborated within the system of the patient. The amount of fever may have an influence in accelerating or retarding the chemical processes, but the degree of fever cannot be said to produce delirium, somnolence, diarrhœa, subsultus, etc.

The statement has often been made that the medical profession, or rather medicine, is the most backward and least developed of all the sciences; but in the consideration of this very subject we are forced to admit that pathology is really waiting for organic chemistry to come up and take rank alongside of it. The late Dr. Austin Flint remarked, during the latter years of his life, "that he believed the future of medical progress lay through the domain of chemistry," and the present indications point strongly toward the confirmation of his statement.

The whole subject of ptomaïnology certainly seems like a reversion to the old humoral theory of the causation of disease; but it differs from it in the fact that the later theory is the result of exact, painstaking, and truly scientific methods of research.

Hysterectomy vs. Apostoli's Method.—Dr. E. S. McKee writes in the *American Practitioner and News:* "Keith has recently reported his hysterectomies for fibroid tumor of the uterus, and gives the mortality of all cases of all operators, if they have reported every case, at twenty-five per cent. This he thinks a terrible mortality. He says it may be higher. In comparing the electrical treatment of Apostoli, he remarks: 'I say it deliberately, hysterectomy is an operation which has done more harm than good, and its mortality is out of all proportion to the benefits derived by the few.' Keith accepts *toto animo* the teachings of Apostoli. In less than five months Keith & Son have applied electricity in strong and accurately measured doses more than twelve hundred times upon more than one hundred patients, the majority being cases of uterine fibroid. The labor of these operations was very great, but it opens out a field for study which daily increases in interest. Several patients came to them for hysterectomy for uterine fibroids. After treatment by Apostoli's method, these women have all gone home without operation, with menstruation almost normal, and improving after their return. In every case the tumor was gone; in one instance only has there been a return of hemorrhage. The tumor had gone down two-thirds, and she was allowed to leave town too soon. Should these improvements remain permanent, and from the experience of Apostoli there is every reason to expect they will do so, the field of hysterectomy is reduced to the narrowest possible limits. I would consider myself guilty of a criminal act were I to advise my patient to run the risk of her life before giving this treatment a fair trial."

Progress of Medical Science.

Incision of the Cyst in Hydatid Disease of Liver.—At a late meeting of the Leeds and West Riding Medico-chirurgical Society (*The British Medical Journal*), Mr. Mayo Robson described the case of a patient admitted to the infirmary, with a history of a swelling in the abdomen of fourteen days' duration, with pain for the last five days. He was looking ill and anxious on admission, with a temperature of 101° F., and there was a tumor in the abdomen yielding an impulse on percussion. The cyst was exposed by an incision outside the rectus muscle, and a multitude of small cysts were withdrawn through a trocar, the whole contents amounting to one hundred and twenty ounces. The edges of the sac were stitched to the abdominal wound, and the cyst was irrigated and drained. The patient made a good recovery. Mr. Robson referred to the various methods of treating this condition, namely, simple puncture, puncture with the injection of a solution of mercuric chloride (ʒ ij. of a 1 in 5,000 solution) as advocated by Dr. Sennett, incision *à deux temps*, and opening by means of caustic paste. He preferred in such a case as above, when the symptoms were urgent, to incise the cyst in one operation, and clear out the daughter-cysts. In the ensuing discussion Dr. Eddison thought it was very important to know whether secondary cysts existed, as, if not, recovery would follow tapping. Even if the daughter-cysts were killed by puncture they would remain as foreign bodies. Dr. Major thought that "hydatid fremitus" was rare and fallacious.

Methylal in Delirium Tremens.—Professor v. Krafft-Ebing, of Grätz, is a believer in the value of methylal in delirium tremens. Acting on the advice of Merck, he employed an aqueous solution of the strength of 1 in 10 as a hypodermic injection. Each injection contained one and a half grain of methylal, and in this strength produced only slight and transient smarting. Thus administered it was found that the drug only produced its effect after an interval of about two hours; if sleep was not produced after between two and three hours, the injection was repeated. Twenty-one persons were thus treated, about half the number being slight cases; in 6 instances sleep was induced by one injection, in 10 by from two to four, in 3 by from five to eight, and in 2 by from ten to twenty; deep, physiological, refreshing sleep, which sometimes lasted twenty hours, was then obtained; in other cases, the patient slept for two or three hours, to wake again delirious; but, the treatment being persevered with, the prolonged so-called critical sleep always ensued. Krafft-Ebing considers methylal to be the best sedative and hypnotic in delirium tremens which he has ever used; it has no depressing action on the heart, but rather the contrary, and it is followed by no unpleasant after-effects. He considers that it is likely to be useful in insomnia and restlessness due to inanition or cerebral anæmia, but that it is contraindicated in cases where there is cerebral hyperæmia.—*Therapeutische Monatshefte.*

Loreta's Operation on the Stomach.—Digital dilatation for fibrous stricture of the pylorus, which was first practised by Professor P. Loreta, of Bologna, in 1882, has already in his hands given most satisfactory results in a large number of cases. The operation was recently again performed by Dr. Loreta. In January last a man, fifty-four years of age, but looking much older, owing to his wasted appearance, came under his care with the following history: He had been excessively intemperate both in eating and drinking, and had suffered from severe dyspepsia since 1872. In 1880 he began to be troubled with vomiting, which occurred regularly four or five hours after taking food. The stomach was visibly dilated, and a splashing sound could be heard on succussion. Microscopic examination of the vomited matters gave negative results; neither blood, starch-granules, nor sarcinæ could be detected. No tumor could be felt in the hypochondriac or epigastric regions; the abdomen yielded readily to pressure with the hand, which, however, caused a slight amount of pain. At the place where this tenderness was most pronounced, a hard fibrous cord was felt at a point corresponding to the situation of the pylorus. On January 30th, after washing out the stomach with an alkaline solution, Loreta made an incision along the linea alba from the xiphoid cartilage to the umbilicus, and exposed the stomach, which was drawn partly out of the wound and opened about midway between the greater and lesser curvatures. The index-finger was then passed into the viscus in the direction of the pylorus, through which, however, it could not be pushed. A large-sized urethral bougie and afterward an œsophageal sound were then passed through into the duodenum. By this means the stricture was so far dilated that the operator was able to get his finger through the pylorus and draw it over almost to the abdominal wound. The index of the left hand was then also passed through on the right as a guide. The pyloric orifice was then dilated by forcible divulsion with the two fingers, a proceeding which the tightness of the stricture rendered very difficult. Finally, the wound in the stomach was closed by continuous, and that in the abdominal wall by interrupted, suture, and an antiseptic dressing was applied. On February 9th the wound was healed, and the patient had completely got rid of his troublesome symptoms. Digestion was perfect, vomiting had entirely ceased, and the man had lost the look of suffering which had been so marked before the operation. Dr. Bufalini, who reports this case, says that not a single instance of relapse after Loreta's operation has yet been heard of.—*The British Medical Journal.*

Bilharzial Epicystitis.—At a recent meeting of the Medical Society of London (*The British Medical Journal*) Mr. Hurry Fenwick showed a patient, aged twenty, who had suffered from Cape hæmaturia for five years, and who had come under observation on September 23, 1887, with symptoms of extra-peritoneal perforation of the bladder of nine days' duration. Ten days previously, after severe exercise, the patient suddenly passed large quantities of blood, and was seized with extreme suprapubic pain. The abdomen was tympanitic in its upper two-thirds, but absolutely dull in the suprapubic region. The dulness was not removed by catheterism of eight ounces of clear urine. The entire recto-vesical pouch was found to be filled with a softish fœtal-head-sized mass. He believed that pericystitis had been set up by incomplete perforation of, and leakage through, the posterior wall of the bladder, and that epicystitis and adherence of the intestines had resulted. A suprapubic incision was made for drainage purposes, but the prevesical space was found, on examination, to be free. The swelling in the recto-vesical pouch was gradually absorbed, and the patient recovered. He still passed bilharzial ova. Electric illumination of the bladder revealed multiple punctiform hemorrhages of the base.

The Pathogeny of Bright's Disease.—The Paris correspondent of *The Lancet* writes that, at a recent meeting of the Société des Hôpitaux, Dr. Gaucher read a paper on the "Pathogeny of Bright's Disease," of which the following is a summary: The excessive introduction or the exaggerated production of extractive matters in the organism is the ordinary pathogenic condition of what the author terms *gros rein blanc* (epithelio-parenchymatous nephritis). The exaggerated introduction or the excessive production of extractive matters suffices of itself to produce the epithelial form of Bright's disease; but if chronic nephritis produced by another cause had already existed, the defective elimination of extractive matters will aggravate the renal lesion. From these experimental facts result important therapeutic teachings. In the first place, there is the danger of employing meat broth in nephritis; for those suffering from Bright's disease "bouillon," or broth, is a poisonous solution. It is dangerous in all maladies; and even in healthy individuals, to employ extracts of meat, concentrated broths, and meat powders, which, besides the toxic mineral salts, principally the salts of potash, contain organic poisons and precisely all the excrementitious matters the noxious action of which has been demonstrated by the experiments undertaken by Dr. Gaucher.

Irritation as a Cause of Tumors of the Bladder.—At a late meeting of the London Pathological Society (*The Lancet*), Mr. Hurry Fenwick brought forward a series of specimens to show that irritation of various kinds plays a most important part in the production of vesical growths. He pointed out that the very earliest form of villous papilloma was to be found in a small patch of stunted papilloma known as subvilloid or cropped villi, and in most of these specimens there existed definite evidence of irritation. Thus, in a case of Dr. Beaven Rake's the patch was found at that part of the bladder which impinged against a straw, four inches and a half long, coated with phosphates. In Dr. Newman's case the tumor was at the apex of the bladder, and seemed due to the irritation of a large oval stone. Mr. Fenwick then alluded to the age and position of villous papilloma as corroborative evidence. In carcinoma he believed that the irritation of residual urine was a most important causative factor, and quoted cases from Stockholm, Glasgow, and London.

Injections of Albumen and Albuminuria.—Dr. Paul Snyers has recently completed a series of experiments undertaken for the purpose of controlling the experiments of Semmola on the pathogenesis of Bright's disease. He injected into dogs white of egg diluted with a small quantity of distilled water. The operations were done by means of a syringe of double the capacity of the ordinary Pravaz syringe. The syringe was carefully disinfected before each experiment, and the quantity of albumen injected varied from four to five grams per kilogram of the animal's weight. When this quantity is compared with the amount of albumen excreted daily by the kidneys in the gravest forms of nephritis, it is seen that the quantity injected into the dogs was incomparably greater than that excreted. After the animals were killed the kidneys were examined in the fresh state by congelation, and after the action of osmic acid, absolute alcohol, Müller's fluid, or boiling water. Continuous injections during three, six, nine, and twenty-three days never produced glomerulitis. At certain points albuminous coagula were found, and a little diapedesis on the interior of the capsule. In no case was there any fatty degeneration of the epithelium. These facts led Snyers to draw the following conclusions: 1. The albuminous (albuminuric) dyscrasia determined by the injection of egg-albumen is transitory, and ceases within twenty-four hours after the injections. The albumen found in the urine is only the white of egg that has been injected. It is a useless substance, passes through the organism, and is eliminated naturally by the kidneys without producing any lesion. 2. Histological examination of the kidneys shows no sign of any lesion of these organs, even after the injections have been carried on for thirty days. 3. The fact that injections of white of egg cause an albuminuria that is absolutely transient, and without action on the renal parenchyma, permits the conclusion: Injections of white of egg are incapable of producing either the lesions of nephritis or a pathological albuminuria. These experiments absolutely contradict the experiments and conclusions of Semmola, with regard to the causation of a clinical picture of Bright's disease by subcutaneous injections of white of egg.—*Journal of the American Medical Association.*

The Comparative Antiseptic Values of Chlorides, Nitrates, and Sulphates.—Mr. C. T. Kingzett, F.C.S., records the results of some experiments which he has conducted in order to determine the relative extent to which certain metallic chlorides, nitrates, and sulphates retard the appearance of mould on flour-paste and putrefaction in extract of beef respectively (*The Lancet*). The general bearing of the results is to show that the salts of the alkalies and alkaline earths, excepting magnesium sulphate, appear in many instances to promote and never to retard the growth of mould. The compounds of zinc resemble those of the alkaline earths in their action. On the other hand, the salts of iron, tin, lead, and aluminium exercise distinct but not very powerful effects in preventing the appearance of mould. The chloride of lead is, however, more active, while the most efficient are the chlorides of mercury and copper. In preventing the putrefaction of extract of beef, the chlorides of mercury and copper were also the most effective; while chloride of zinc was more, and chloride of lead less, active than in retarding the growth of mould on flour-paste. The value of the investigation is very much reduced owing to the experiments not having been conducted on the modern lines of bacteriological research. Thus the various test-glasses containing the experimental media were allowed to become accidentally infected from the air to which they were exposed, instead of being all inoculated either with some definite micro-organism or with some definite mixture of microbes, as is now invariably done in experiments of the kind.

The Treatment of Inflammation in the Region of the Ileo-cœcal Valve.—From a study of this subject, Dr. M. H. Richardson has arrived at the following conclusions: 1. In mild cases of inflammation in the region of the appendix there should be no surgical interference till physical examination reveals the presence of an abscess, which should be incised by the post-peritoneal method. 2. In violent cases, where it is evident that there is a general peritonitis, laparotomy should be done immediately, just as soon as a diagnosis of general peritonitis has been made. 3. In violent cases, where it is doubtful whether the general peritoneal cavity has yet been invaded, and where the history and the physical examination favor the presence of an abscess in the ileocæcal region, though it is impossible to locate the exact seat of the inflammatory process, an exploratory incision should first be made in the right iliac fossa, and the ileocœcal region explored post-peritoneally. 4. The best incision to reach the appendix in the average case is along the outer border of the rectus, about four and a half inches from the spine of the pubes. 5. The best incision for extra-peritoneal exploration is parallel and close to Poupart's ligament, beginning in about the centre, and extending outward and backward a sufficient distance.—*The Boston Medical and Surgical Journal.*

Sour Milk in Summer Diarrhœa.—The house surgeon of the Prison Zweibrücken, Dr. Osthoff, has in two annual reports spoken very favorably of the employment of sour, curdled milk in summer diarrhœa, in adults as well as in children. Dr. Osthoff endeavors to explain the beneficial action of sour milk in the following way: He believes that the bacilli of sour milk destroy and overcome, by their rapidity of growth, the other micro-organisms that are the cause of the diarrhœa, and that they thus bring the process to a stand-still. In addition to its value as a dietetic agent in summer diarrhœa, it proved exceedingly useful in all chronic abdominal affections associated with dyspepsia, in chronic intestinal and hepatic diseases with diarrhœa, or constipation, in jaundice, and as an article of diet in typhoid, pneumonia, and erysipelas. In tuberculosis of the intestines, however, it increased the diarrhœa. It forms a valuable means of support to Oertel's treatment in cardiac cases, and cases of emphysema, in small quantities, as a substitute for coffee, wine, beer, and water, as a thirst-quenching drink, as well as a food containing both muscle and fat-forming material in one and the same form. At the instance of the Bavarian Ministry Professor von Voit worked out an official report on this sour-milk therapeutic, and from this some interesting details may be extracted. Sour milk very much resembles fresh milk as a food (four per cent. albumen, three per cent. fat, four per cent. sugar). The use of it is to be recommended as an addition to the needful amount of hydrocarbons. Moreover, especially in summer, it forms a refreshing drink, and may be ordered with advantage in dyspepsia. The action of sour milk is very varied; sometimes it causes constipation and sometimes diarrhœa. For this reason he recommends that in infantile diarrhœa it shall be used with caution. In general, he recognizes the value of sour milk as an article of diet. A writer in the *Deutsche Medizinal Zeitung*, commenting on the above, draws attention to the similarity of sour milk and kefir. Both are used in phthisis. Koumiss at one stage (when fresh) is known to relax the bowels, while at another it constipates. It is the same with kefir, and doubtless it will be the same with sour milk; as it gets older it becomes more constipating. Dr. Osthoff has done well in drawing attention to a neglected and very useful article of food.—*Berlin Correspondence Medical Press.*

Fatal Intoxication from Dilute Solutions of Bichloride of Mercury.—Steffeck, of Hofmeier's Clinic at Giessen, reports the following case, which is instructive as an instance of fatal intoxication after the use of but two intrauterine douches of weak solutions of mercuric chloride. The patient was a multipara, who miscarried at five months with a macerated fœtus. Her antiseptic treatment consisted in a bath on admission to the hospital; cleansing of the external genitals with 1 : 1,000 solution of bichloride of mercury; and vaginal douches of 1 : 3,000 bichloride solution given once daily, in quantity of one quart, during the five days in which her miscarriage occurred. The placenta was retained after the expulsion of the fœtus; as hemorrhage persisted to some extent, the vagina was tamponed with iodoform gauze. After the placental retention had persisted for more than twenty-four hours, the patient was anæsthetized, the customary vaginal douche given, an intrauterine douche of one quart of 1 : 5,000 was used, the placenta removed, and an intrauterine douche of one quart of hot mercurial solution, 1 : 5,000, was employed to check the hemorrhage; ergotin was also administered. One hour after the removal of the placenta pronounced symptoms of mercurial enteritis supervened, followed by stomatitis and acute nephritis, with anuria. Death occurred in seven days after poisoning. The post-mortem examination revealed dysenteric enteritis, acute parenchymatous nephritis, with slight emphysema and pulmonary œdema. The intestinal lesions were so pronounced as to be typical. Steffeck ascribes the poisoning to the intrauterine douche which was given after the removal of the placenta, when he thinks that the mercurial entered the circulation directly through the placental site. In view of the dangers of intrauterine douches of bichloride of mercury, their use has been abandoned at the clinic at Giessen. Vaginal douches only, of bichloride solution, and these preferably before labor, are now permitted. In commenting upon his case, Steffeck emphasizes the fact that every precaution was taken to empty the uterus after the douche, and that uterine contraction after the expulsion of its contents was excellent. The cases reported by Fleischmann and Von Herff are somewhat similar, but not so striking examples of direct intoxication. —*The American Journal of the Medical Sciences*, April, 1888.

The Elimination of Medicines by the Mammary Glands.—From a study of this subject, Dr. John G. Cecil has arrived at the following conclusions: 1. That the practice of medication of the child through its nurse's milk promises very little, and is altogether too uncertain to be relied on. 2. That great caution should be observed in the administration of narcotics to nursing women. 3. That greater care than usual is demanded in the exhibition of drugs during the first few days after parturition, and when, for any reason, the milk is poor and thin in quality.—*The American Practitioner and News.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, May 19, 1888.

PECULIAR TYPES OF PLEURISY.

A STUDY of diaphragmatic pleurisy was made by Dr. Frank Donaldson, Jr., some two years ago (*Amer. Journal of the Med. Sciences*). He showed that primary inflammation of the diaphragm was rare, though it sometimes occurred in acute rheumatism and as the result of wounds. Much more frequently we observe diaphragmatic pleurisy. secondary in character, as the result of general pleurisy, pneumonia, peritonitis, fractured ribs, violent laughter, tight lacing, etc. It occurs, also, in phthisis, and it may result from cysts, abscesses, or tumors of the abdominal wall. It occurs oftener in the young, and in women. The patients suffer from pain along the attachment of the diaphragm, and in the neck and shoulder. The position of the patient is peculiar, the diaphragm is almost motionless, the breathing costal. Dysphagia occurs, but is not pathognomonic. Primary cases run a rapid course, and recovery occurs. Secondary cases are usually fatal. Jaccoud considers that the dry, harassing cough, easily excited by pressure upon the borders of the ribs. is very characteristic of diaphragmatic pleurisy.

This same author, in a clinical lecture delivered recently at La Pitié (*L'Union Médicale*), presented a case of diaphragmatic pleurisy of a typical kind, and dwelt especially upon the relation of such disorder to phthisis. Jaccoud's views upon this subject are well known. Phthisogenic pleurisies are not those attacking the apex especially. They occur rather in antero-lateral portions of the chest. They are dry pleurisies, but there is sufficient exudation because adhesion occurs. This adhesion weakens expansion, and is, in general, the focus of a later-developed tuberculosis. Jaccoud appears to think that diaphragmatic pleurisies may be equally serious as factors in causation of phthisis.

Pulsating pleurisy is a peculiar and rare form of disorder, described by Cornby in 1883, later by Eichorst, and recently discussed by Dr. Alfred Keppler (*Deut. Arch. f. Klin. Med.*, Bd. 41. Heft 3). The last-named author has collected and studied 38 cases. Pulsating pleurisy is generally a suppurating pleurisy, occurring on the left side. The co-existence of pericarditis, of air in the pleural cavity, and of paralysis of the intercostal muscles. are factors called in to explain the phenomenon.

The causes of sudden death in pleurisy have been studied by Dr. Edmond Weill (*Rev. de Médecine*, 1887, No. 1). In 20 cases in which post-mortem was made. myocarditis was found in 2; thrombosis or embolism of the heart in 9 cases; acute œdema of the lung on the healthy side in 6 cases; pericarditis and perforation of the lung were found in the others.

Atrophy of the muscles of the thorax and shoulder has been found by Dr. Desplats (*La Semaine Médicale*, June, 1887) in those who have recovered from pleurisy. This atrophy is often decided, and is, the author thinks, one of the elements which make a pleurisy predispose to subsequent development of phthisis.

LOW MEDICAL FEES.

The Druggists' Circular says: "While we hear a great deal about the evil of counter prescribing, not much is said about the contributory evil of high physicians' fees. As a rule, medical fees are always much too high in proportion to the earning capacity of most people who have to pay them. A man in the humble walks of life, who is compelled to have the visits of a doctor for, say, a week, finds himself with a bill as large as his week's earnings, to say nothing of the added cost of the medicines prescribed, and a consultation with a medical man at his office for five or ten minutes costs as much, at least, as such a patient can earn by a half-day's work."

We have always contended that it would be wiser for physicians to take small fees than to send all their indigent patients to the dispensaries or the drug counters. It might be a much better plan if physicians had certain hours for poor patients. At present the tendency is in cities to make the rich pay exorbitantly in order that the poor may be treated for nothing. And charity treatment is never so good as that rendered in return for some payment, however small.

NASAL STENOSIS AS A CAUSE OF HERNIA.

THE causes of hernia are generally stated to be a congenital deficiency or laxity of those parts of the abdominal parietes which go to form the inguinal, femoral, or umbilical openings. The exciting causes are considered to be sudden increase of intra-abdominal pressure, due to strain, coughing, etc. Roser's lipoma theory of the origin of hernia has not excited very much attention, except among German surgeons. Nor has there been much which is new suggested regarding the exciting causes.

A very laborious study in this last line, however, has recently been made by Dr. W. Freudenthal, of this city, who, in an article "On the Relation between Chronic Obstruction of the Nares and Abdominal Hernia," tries to show that the former condition bears an etiological relation to the latter.

Dr. Freudenthal thinks that nasal stenosis, from hypertrophy, adenoid vegetations, chronic catarrh, etc., is a potent factor in producing hernia.

The constant hawking, coughing, sneezing, and spitting of this class of sufferers raises intra-abdominal pressure, and tends to the development of hernia. He notes the case of a German family which came to this country. A large part of its numerous members developed nasal catarrh, with obstruction and hernia.

He set to work to study the matter systematically, and examined the nose and throat of five hundred ruptured children, patients at the Hospital for Ruptured and Crippled. In a very large proportion serious nasal stenosis existed, while in not a single case was the mucous membrane perfectly healthy!

Whether five hundred New York children, not ruptured, would present the same proportion of nasal disease is not known. It seems somewhat unlikely, despite the fact that nasal and pharyngeal disorders are so prevalent in this city.

If, however, nasal stenosis helps to produce hernia, and if, as is usually believed, nasal catarrh and stenosis are more common in the United States than in Europe, it ought to follow that hernia is more common. This is hardly the case. Among 1,000 recruits for the Northern army, 50 were rejected on account of hernia. In Germany, the proportion of recruits rejected on account of hernia is 82 per 1,000; in France, 65; in Italy, a country that presumably does not suffer from excessive nasal or pharyngeal troubles, it is 76. We can hardly admit, therefore, that Dr. Freudenthal has proved his theory, though the observations which he made are of themselves valuable.

MERYCISM AND THE MERYCOLE.

Two or three years ago attention was called by French writers to a condition termed merycism, or rumination in man. Several cases were reported, and the phenomenon was shown to be not especially rare, and to be possibly on the increase. Dr. E. Martel even claimed that merycism was a condition toward which civilization was forcing man, and that in time we would all be ruminants. The "merycole" was observed to be a person of highly nervous organization, a very rapid and voracious eater, with atonic stomach. The rapid accumulation of food in the stomach paralyzed the secretory function, and caused a sense of oppression. Through a peculiar laxity of the cardiac sphincter, the food could be easily returned to the mouth for complete mastication. The habit of rapid eating, the nervous temperament, and the dyspepsia, all exist in this country. We may well suppose, therefore, that Americans will become "merycoles," if any nation does; and it is well to understand the matter in time.

Two new cases of merycism have recently been reported, and it is significant that one of them was observed in the New World. Dr. J. M. Bandera reports it in the *Gaceta Médica de México*, 1887, p. 480 (*Revue Internationale des Sciences Médicales*, 1888, No. 2). The patient was a physician, fifty years of age. He had a good personal history, and had never suffered from any nervous disorder. The regurgitation of food had taken place since his youth. Meat, cheese, salad, raw fruits, were brought up at intervals of five or ten minutes for two hours after a meal. They were masticated and swallowed again. The patient's digestion was fairly good, but slow.

The second case was reported by Dr. Karl Debio, in the *St. Petersburg Medicin Wochenschrift*, January 14, 1888. The patient was a young man, of nervous temperament and hypochondriacal tendencies. He had ruminated since the age of twelve, the disorder beginning after an attack of whooping-cough. The stomach was found to be slightly enlarged.

In the first case just referred to, rumination developed also in the patient's child, and other cases of hereditary merycism have been observed.

The association of merycism with idiocy and insanity is well known. Bourneville found that about five per cent. of idiots had this disorder. Bouchaud found fourteen cases in an insane asylum containing 572 inmates. Bourneville and Seglas collected a large number of cases occurring in persons not insane, and it has often been observed in persons apparently of sound nervous system.

SULPHO-CYANIDE OF POTASSIUM AND THE URIC-ACID DIATHESIS.

Some time ago attention was called to the diagnostic significance of variations in the amount of sulpho-cyanide of potassium (Civks) in the saliva. This substance averages about one hundred and thirty milligrammes in twenty-four hours (Landois), but is subject to decided changes. It is not found at all in the saliva of many lower mammals. Its presence, significance, and origin have been the subject of much rather fruitless speculation.

Dr. M. G. Bruylants, in a series of communications to the Royal Academy of Medicine of Belgium, claims to have solved in a measure the mystery of the relation of this substance to the economy. He has found sulpho-cyanic acid as a normal ingredient, not only in the saliva, but in various secretions and fluids of the body, viz., the urine, blood, bile, milk, and even in the amniotic fluid. He states that as a rule a litre of urine contains about one-twentieth as much of the acid as a litre of saliva.

Sulpho-cyanic acid is, therefore, a normal product of tissue-disintegration. Its chemical history is therefore to be studied, as possibly throwing light upon pathological changes.

M. Bruylants finds that different persons living upon the same diet excrete different amounts of the acid in the saliva and urine, and the amounts differ while the individual continues on the same diet. Hence, he concludes that it is not introduced in the food. The amount in a litre of saliva is about a grain; in a litre of urine, about one-twentieth of a grain.

A long series of experiments is recorded, intended to determine the exact chemical process by which this compound is formed in the organism. The conclusions are: First, that the sulpho-cyanic acid is formed in the animal organism, and is derived from albuminoid decompositions alone, probably by a combination of the group CN, and of sulphur; second, that the formation of sulpho-cyanic acid depends upon the nature of the nitrogeneous excretion. When this is complete, and urea is in proper amount, the sulpho-cyanide is excreted normally. But in the uric-acid diathesis the sulpho-cyanide almost or entirely disappears from the urine. This furnishes, therefore, another test of the gouty or lithæmic state.

OBLITERATING ARTERITIS.

Among the disorders the knowledge of which modern pathology has furnished us is the so-called obliterating arteritis. This, in its chronic forms, has now been quite thoroughly studied. Certain subacute forms, however, have been recently described, and the studies made upon them furnish an instructive contribution to clinical medicine and pathology.

Some time ago, Dr. Hadden and Mr. Pearce Gould reported three cases of obliterative arteritis affecting the ar teries of one extremity. Recently Dr. W. J. Walsham (*The Lancet*, March 24, 1888) has reported a fourth case, and the symptoms in each instance were so very similar that the disease seems almost to merit a distinct clinical name. In no case was there a history of syphilis or alcoholism, nor could, in fact, any cause be assigned. The disease spread from below upward, reaching as high as an inch below the clavicle. There was the same indurated, tender, and pulseless condition of the radial, ulnar, brachial, and lower portion of the axillary arteries, and the subclavian artery formed an aneurismal-like swelling, the size of a small hen's egg. The swelling could be emptied by pressure, and there was no bruit heard in it. The hand and forearm were cold, and the tips of the fingers cold and bloodless. There was no swelling of the extremity, and no engorgement of the superficial veins of any part of the limb. The pain in the hand and forearm was intense, and the disease, after lasting for several months, subsided spontaneously. In all these respects the cases were alike. In two cases, however, gangrene set in, and in one case the dilatation in the subclavian artery varied greatly from day to day.

Dr. Walsham thinks that the disease has a nervous origin, and it appears to us also that it may have some relation to so-called Raynaud's disease.

Another form of obliterating arteritis, decidedly different in type, is described by MM. Dejerine and E. Huet in the *Revue de Médecine* for March, 1888. The case reported is one of subacute obliterating aortitis affecting the whole arch and part of the thoracic aorta. This part of the circulatory system is known to be especially prone to disease, but more particularly to chronic aortitis ending in atheroma and aneurismal dilatation. Instances in which the aorta is subacutely inflamed, if not rare, are at least rarely diagnosticated. The patient was a man forty-five years of age, who had not had syphilis, but who had drunk to a considerable extent, and had suffered exposures. His illness lasted about nine months. During the last three months the symptoms became marked. He suffered from attacks of angina pectoris, dyspnœa, and great weakness. He showed signs of aortic regurgitation. There was a marked supraclavicular pulsation on the left side, a full bounding pulse in the left radial, while in the right it was almost imperceptible. The precordial pains were very violent. The patient had finally an attack of syncope, and died. The heart presented very few signs of disease, while the aorta, from its beginning as far as its thoracic portion, showed a very intensely marked obliterating subacute inflammation. This inflammation was sharply limited at the points where its branches were given off, but it had merely obstructed the orifices into all these branches. So far as the cerebral circulation was concerned, it was found that the brain was nourished *by only one artery*, and that the vertebral; yet no cerebral symptoms had followed.

The authors collect a few other cases of obliterating aortitis reported by Germoul, Leger, and Ozenne. None are so typical as their own, however, or throw so much light upon the symptomatology of this obscure disorder. Incidentally they affirm that the symptoms of angina pectoris are not as a rule produced by the disease of the coronary arteries, but may be caused by arterial or cardiac disease elsewhere.

HYPEREMESIS GRAVIDARUM.

Dr. Theophil Jaffé, of Frankfort, describes, in Volkmann's *Klinischer Vorträge*, No. 305, a case of uncontrollable vomiting of pregnancy, ending fatally. The disease is, he says, very rare. at least in Germany, and he takes his case as a text for a systematic description of hyperemesis gravidarum.

As Paul of Ægina considered the "vomitus assiduus" of pregnancy not dangerous, it seems that the pernicious form was unknown to him. It was described in the eighteenth century by Mauriceau and Delamoth, and in the beginning of this century by Burns (1809) and Simons (1813). In the last thirty years much has been written upon it, especially by English and American physicians. In this country the trouble is not excessively rare.

Statistics of 118 cases show that it occurred in primiparæ 43 times; in multiparæ 75 times. Studies of reported cases show that the obstinate vomiting may develop directly after conception, or even as late as the seventh month of pregnancy.

The intimate pathology of the disorder is unknown. It is presumed that it must be a reflex neurosis. The stomach is richly supplied with nerves, which come from the left, and part of the right, vagus, and from the sympathetic branches of the cœliac plexus. The uterine organs, also, have a double nerve-supply from the spinal nerves and the utero-vaginal plexus of the sympathetic. There is nothing in this anatomical arrangement that throws much light upon the mechanism of the hyperemesis, except to show that a reflex or transfer of sensations is possible. In some cases of hyperemesis there have been found inflammatory conditions of the uterus, purulent infiltration, exudates, tumors, cysts, etc., but such changes are not always observed, and they may occur without causing uncontrollable vomiting. Malpositions of the uterus, vaginitis, excessive distention from hydramnion, appear to explain the irritation in some cases, but not in all.

The prognosis of hyperemesis gravidarum is very bad, though not absolutely unfavorable. The older authors gave a mortality of forty-four per cent. Joulin, in 121 cases, found that death occurred in 49. Horwitz lost 5 out of 13 cases. Such statistics are not of much value. It is evident enough, however, that about half the cases die.

The treatment consists in using nutrient rectal injections, in the employment of antiemetic drugs, in local applications to the cervix, and, finally, in producing abortion. Copeman's plan of stretching the cervix has sometimes been effective. In other cases it has done no good, and in still others it has produced abortion (Jaffé).

As to the efficiency of this last-named measure there can be no doubt. Statistics collected by Guéniot show that, among 118 cases, 72 were cured; 31 by drugs, etc., 41 after abortion. Carataga found, among 117 cases, only 14 cured. M'Clintock reports 36 cases, of which 27 were cured by abortion. Cohnstein's statistics include 200 cases. Of these, forty per cent. were relieved by abortion, and twelve per cent. died.

Such figures do not throw much light upon the real utility of the operation. It is felt to be very generally true that abortion, if successfully performed, will inevitably relieve the disorder.

The course of the disorder has been divided by some authors (Guéniot, M'Clintock) into three periods; by others (Horwitz), into two.

The first stage is afebrile; the vomiting may now be moderate, and some food can be retained. But there is much thirst, and pains in the stomach; constipation and salivation occur. Horwitz has observed "hyperæmia" in two cases. The patient begins to emaciate.

In the second stage there is slight fever, the pulse is more rapid and weak, the respiration more frequent. The tongue is dry and coated, the breath foul, there are constant epigastric pains. The urine is concentrated, and shows albumin and casts.

In the third stage there is high fever; great emaciation and weakness, delirium, sopor, and death, too often end the scene.

The duration of the fatal cases is about three months. When, by abortion or otherwise, a change occurs, the duration is about two months.

IS THE MODERN TREATMENT OF PNEUMONIA A FAILURE?

We meet at quite regular intervals contributions from writers who laud the ancient methods of treating acute inflammatory disorders by bleeding. Special pleas of this kind receive a perfunctory notice, and then are usually dropped from the memory. Venesection is not the vogue. The laity have been taught for forty years that it is an old-fashioned and dangerous practice. And the doctor who attempts its use is regarded as unsound.

But Dr. Henry Hartshorne has recently brought forward some facts in connection with this subject which deserve more than ordinary attention. In a paper read before the College of Physicians of Philadelphia, February 1st, he advances the following views: First, that pneumonia is much more fatal now than it was when venesection prevailed. Second, that this increased mortality cannot be explained by change in type or change in constitution. Third, it must be due to change in treatment. *Ergo*, the modern treatment of pneumonia is wrong.

With regard to the first point, Dr. Hartshorne publishes the results of treatment of 11,175 cases of pneumonia by between forty and fifty physicians of Great Britain, Ireland, and Europe, in the first half of this century. This shows a mortality under treatment by bleeding of 1 in 11.1 cases; by large bleedings alone, 1 in 11.6. In this country in the United States Army, between 1840 and 1844, when treatment by venesection prevailed, the mortality was 1 in 11.5 among 1,416 cases. Between 1855 and 1859, after venesection was given up, the mortality was 1 in 6.67 among 657 cases.

In the Pennsylvania Hospital, from 1845 to 1847, the mortality was 1 in 16; from 1884 to 1886 it was 1 in 3.2. The ordinary mortality from pneumonia in large general hospitals in this country is now stated to be about 1 in 4. The mortality as determined by the British Collective Investigation Committee was eighteen per cent. In venesection times Skoda's estimate of pneumonia-mortality was 1 in 8. In the hospitals of Europe, 1822 to 1856, the average mortality was 1 in 20.66. The conclusion seems inevitable from the figures given, therefore, that relatively over twice as many persons die now from pneumonia as died fifty years ago.

This is a case, however, in which statistics may be misleading, and very likely an industrious compiler might cite other figures to offset those above given. For example, Warfwinge, among 546 cases (not alcoholic), found the mortality to be 6.2 per cent., and Fraentzel states that he saw 100 cases among soldiers without a death. On the other hand, the average mortality in the Christiana Hospital, from 1845 to 1875, according to Winger, was 16.8 per cent. In the St. Petersburg Hospital it was twenty-one per cent. (Eichorst).

Dr. Hartshorne's opinion that this increase in mortality is due to bad treatment is one that is very hard to prove, but if proven would be a most serious indictment of modern therapeutics. Of late years the treatment of croupous pneumonia has been more and more based upon the expectant and nourishing plan. Opium is sometimes given; so also is quinine, alcohol, and antipyretics. The antipyretic method we consider to have been distinctly pernicious, but fortunately it had but a short career. Instead of expectancy, quinine, alcohol, antipyrin, etc., Dr. Hartshorne recommends that moderate bleeding be employed, except in the aged, the asthenic, alcoholic, and those with Bright's disease. Such bleeding may be local, by means of cups or leeches, or the blood may be taken from the arm. The venesection should always be done early in the disease, and only then. At this time, also, a purgative is indicated. If a change in treatment can improve the mortality-rates in our hospitals and bring them back to those of earlier days, we trust such change will be made. At any rate, Dr. Hartshorne's imputation upon the modern treatment of pneumonia deserves a careful examination.

HYPERARTERIAL TENSION AND ITS TREATMENT.

Much light upon the nature of a patient's condition, and much help in therapeutics, is given by a study of the tension of the arteries. In this particular field the sphygmograph has won what little reputation it possesses for practical utility in medicine. An interesting review of some of the conditions in which hyperarterial tension is found has been given by Dr. J. P. Bramwell in the *Edinburgh Medical and Surgical Journal* for March, 1888. Excessive tension of the arteries is found in a great variety of conditions, of which the following may be particularized:

1. Certain blood-poisons, either introduced from without or generated in the system, may cause abnormal tension. Among the former class are ergot and lead; among the latter are the products of faulty metabolism, like uric acid. Perhaps the high tension in Bright's disease and in pregnancy may be due also to this latter cause.

2. In some acute diseases of a specific character, such as scarlatina, diphtheria, and cholera, we find marked arterial tension; while in others, of which typhoid is a type, the pulse is dicrotic or hyperdicrotic, the arterial tension being very low. But when albumin appears in the urine of typhoid patients, as indicating the presence of intercurrent parenchymatous nephritis, the pulse loses its dicrotic character, and is transformed into one of hypertension.

In acute peritonitis the pulse is, as a rule, of low tension, but, when the abdominal sympathetic is much irritated, the arteries contract and the pulse becomes one of hypertension.

In acute and chronic interstitial nephritis, and in most cases of parenchymatous nephritis, the pulse is one of high tension; but in amyloid kidney it is low. There is an abnormally tense pulse in atheroma of the arteries—endarteritis. The pulse is also hard in cases of angina pectoris, and just before epileptic and migrainous attacks. Hypertonus may be therefore either paroxysmal or constant.

Dr. Bramwell classifies the causes of hypertension as follows:

a. Renal diseases and affections, acute and chronic.
b. Vascular system atheroma.
c. Angina pectoris.
d. Diseases of the blood and anæmia.
e. Acute diseases.

The relation of renal diseases to arterial tension is discussed at length by Dr. Bramwell. Two antagonistic explanations have been given of the hypertonus in these disorders: First, that of Johnston, Dickenson, Goodhart, and others, viz., that prolonged arterial strain produces, as a primary consequence, a thickening of the muscular coat of the arteries; this after a time may be followed by other changes of an inflammatory or degenerative character, such as endarteritis deformans, calcification, atheroma, or arterio-capillary fibrosis. Second, Gull and Sutton contend that strain is not the causation in these changes, and that, besides, the changes referred to are degenerative and not inflammatory. Further, that cases have been observed of extensive arterial degeneration (arterio-capillary fibrosis) where the kidneys have not been implicated at all, nor the heart hypertrophied, but where the arteries of the cord, liver, and brain, have all shown the hyaline degenerative character without any general thickening of the muscular coat at all. By these distinguished physicians the pathological changes referred to are regarded as tangible indications of a general senile degeneration, in which the kidneys may or may not participate—at all events, in which they are not the chief factors.

Our author defends very warmly the older view that the hypertonus is secondary. We believe, however, that while such may be the case in some instances, there is a large class of patients, especially those more advanced in life, in which the fibrous and degenerative changes occur in the arteries and kidneys as the result of a common cause, and the expression of a common condition.

In the treatment of hypertonus, the drugs and other remedial agents which may be employed are nitro-glycerine, nitrite of amyl, sodium nitrite, spiritus etheris nitrosi, and potassium bromide; purgatives, such as compound jalap powder; diaphoretics, as pilocarpine, vapor baths and warm pack; blood-letting, general and local; dietetically, skim or buttermilk in quantity. To this list American physicians would add aconite and veratrum viride.

In the hypertonus of acute nephritis, our author especially insists upon the value of blood-letting, and we can heartily indorse his practice here. Nitro-glycerine is also recommended in the same condition; while, as a prophylactic as well as a curative agent, skim-milk and buttermilk are to be given. We are reminded of the statement of Jaccoud that, since he began to feed his scarlet fever patients on milk alone, he has never had a renal complication. The hypertonus of anæmia is best combated by adding nitro-glycerine to the iron and arsenic which may be given.

In the hypertonus of gouty conditions, diaphoretics and purgatives must be added to the arterial sedatives given. Fat people who try to reduce their weight by living on lean meat get an accumulation of nitrogeneous matter in the blood, which causes high arterial tension, and may even produce apoplexy. Such persons need purgatives and diaphoretics. Dr. Galabin has shown that in some cases of peritonitis there is high arterial tension, and that such persons may need nitro-glycerine as well as free stimulation.

We have touched upon enough of the points in Dr. Bramwell's paper to show the importance and suggestiveness of the topic. The physician of to-day makes no such finical classifications of pulses as were established by Galen, but he has learned that the element of "hardness" may be quite as important as that of strength, frequency, or regularity.

THE MORTALITY-RATE AMONG PHYSICIANS.

The Gotha Life Assurance Bank publishes some statistics of the mortality among its policy-holders during 1887. From these it appears that the mortality of the medical members was 11.53 per cent. above the average of that of all the members taken together. The classes of disease to which this higher rate of mortality was due were diseases of the respiratory organs, phthisis, and infectious diseases—"typhus" having proved especially fatal to the younger members of the profession. There was only one case of post-mortem poisoning out of 1,052 deaths, and that was of a district physician. Cerebral apoplexy was remarkably frequent, beginning as early as thirty six years of age. There were 14 cases of suicide and 4 of accidental death. These are, however, below the general average.

Rutland's Medical College.—*The New England Medical Monthly* gives an account of a curious medical college which exists at Rutland, Vt. The institution was incorporated under the laws of Vermont a year ago, and a class of six has already been graduated. It seems that all the sessions of the school are held in Boston, but the Commencement takes place in Rutland. It is, we are told, nothing more or less than a diploma mill which works in Boston and dumps its products in Rutland. If the facts are correctly stated, the existence of the institution is a reproach to Vermont's medical laws, and we trust that the profession of the State will look into the matter.

"Acromegoly" is the title of a curious disease in which the feet, hands, and face are affected. It is more than a simple "large-footedness," and we would warn envious critics of St. Louis that it is not a disorder peculiar to Chicago, but has recently been described by Marie in France. Friereich also reported cases, and in the last issues of the English journals are accounts of several cases seen in London. One case has been observed also in this country, the patient now earning a steady income in a dime museum.

News of the Week.

The American Society of Microscopists meets in Columbus, O., on August 14th.

State Medical Societies.—During the present week the Illinois State Medical Society met at Rock Island; the Iowa State Medical Society met at Des Moines, and the West Virginia Medical Society, at Huntington. Next week the Connecticut State Medical Society meets at New Haven, beginning May 23d.

John B. McIntyre, M.D., died in this city, on the 6th inst., of acute peritonitis, the result of perforation of the appendix vermiformis. He was graduated from the College of Physicians and Surgeons, of this city, in the class of 1877, and at the time of his death was in his forty fourth year, and in the enjoyment of a lucrative practice. He was born in New York City, was never married, and leaves a father, three sisters, and one brother, Dr. B. C. McIntyre, of this city, to mourn his loss. Dr. McIntyre was a man of fine medical ability and sterling integrity; was devoted to his profession, and was respected and esteemed by all who knew him.

New Remedies.—Phenacitin, an ethylized phenol discovered by Hinsberg and Kast, is claimed to be a safe and efficient antipyretic, acting like antifebrin, but having no dangerous effects. Its dose is from gr. iv. to gr. viij. Sulphonol, a compound of ethylmercaptan with acetone, is said by Professor A. Kast to be a good hypnotic, in doses of forty to sixty grains. Dr. G. Rabbas confirms the results of Kast, and thinks that sulphonol is a more sure and agreeable hypnotic than amylene hydrate, or paraldehyde.

Tetanin is the ptomaine that is produced by the growth of the bacillus which Nicolaier, Flügge, and Rosenbach have all shown to be pathogenic of traumatic tetanus. Professor Brieger recently examined, chemically, the amputated arm of a patient who was suffering from tetanus, and he found *tetanin* in the tissues.

The Ethics of Washing out the Stomach.—Our esteemed contemporary, *Gaillard's Medical Journal*, says: "We are credibly informed that it is not unusual, in the city of Washington, for young men, before going to dinner parties, in order to better prepare themselves to play the part of gluttons, to wash out their stomachs a short time before the appointed hour." Our contemporary is pained at such popularization of a valuable hygienic and therapeutic measure. We venture, however, to say a word in behalf of these young men. The practice of stomach washing is a legitimate one. There is no reason why a young man should not wash his stomach as well as his face before going out to dinner, and there is no doubt that the youth of Washington do both. It might even be regarded as an act of courtesy to the host to bring to his table a stomach that has been scientifically laundried, and which lies in neat and antiseptic emptiness folded beneath the diaphragm. Perhaps America, with the curse of dyspepsia upon it, needs more such young men as are produced in Washington. Our contemporary should not too hastily condemn the fresh enthusiasm for clean mucous membranes that is developing in our nation's capital

The New York Legislature which recently adjourned passed laws empowering the State Board of Health to make rules and regulations for protecting from contamination all public supplies of potable waters and their sources within this State; making it the duty of local Boards of Health to destroy all animals affected with glanders; reducing the fees of the Health Officer of the Port of New York, and fixing his salary at $10,000.

A New Home for Consumptives has recently been opened in Brooklyn. It contains forty-two wards, in each of which there are from one to eight beds. The cost of the building is estimated at $70,000.

Improving the New York Quarantine Stations.—The supply bill of the last State Legislature contains, we are informed, provisions for the better equipment of the quarantine establishment at this port. It provides $50,000 for general repairs, $25,000 for a new hospital ship, $5,000 for the hospital, $2,500 for repairing the docks, $121,843 for putting Hoffman Island, the boarding station, and the Health Officer's residence in order, and $20,000 for a new tug; making a total of $224,343.

Antipyrine and the Salicylates in Rheumatism.—Dr. Charles Bayoux, in a Paris thesis, asserts as the result of his studies under Professor Sée, that in acute rheumatism with albuminuria, or with a highly nervous temperament, antipyrine is preferable. The salicylates fail in chronic rheumatic pains and in gonorrhœal rheumatism, while antipyrine acts promptly in these conditions.

A Vienna Physician, named Horéath, "whose clientèle is essentially aristocratic," says a despatch, has recently been arrested, charged with having produced more than two hundred abortions.

Medical Heroism.—The *British Medical Journal* mentions as an instance of the devotion of medical men to humanity the case of Dr. Landon, a surgeon in the British army. Mortally wounded himself, and with the agonies of death closing in, he heard a wounded soldier shrieking from his sufferings. Forgetful of self, he crept to where the man lay and gave him a hypodermic injection of morphine to relieve his distress, and giving it, died.

In the Death of Professor Edward S. Dunster, of Ann Arbor, Mich., which occurred on May 3d, the profession loses one of its best teachers, and a learned and talented physician. Professor Dunster was for a time editor of the *New York Medical Journal*, but he was best known for his work as professor of obstetrics. He had taught in the University of Vermont, at Dartmouth Medical College, at the Long Island Medical College, and at the University of Michigan.

Statistics of the Medical Profession in France.—According to recent statistics, the number of doctors practising in France is 11,995, and that of officiers de santé 2,794. In Paris alone there are 2,188 doctors and 182 officiers de santé. In some departments there are more officiers de santé than doctors. The number of pharmaciens, or chemists, reaches 7,100, of whom there are 797 in Paris. Consequently there are two doctors for one chemist in the whole republic. The midwives are put down as 13,610, and the herbalists as 1,013.

Flies and the Doctor's Horse.—A large fortune awaits the man who will devise a remedy which will keep flies from worrying the horse in summer, and at the same time not kill the horse. Carbolic-acid washes, the aromatic oils, especially pennyroyal, and various other drugs. to say nothing of mechanical appliances, have all been used, but with only temporary benefit. The oil of bay is said to be particularly efficient, and to be extensively used in Switzerland and the South of France.

Transplanting the Cornea.—We learn from a Philadelphia daily paper that an ophthalmologist of that city has performed Von Hipple's operation upon a woman suffering from opacity of the cornea.

Tolstoi's Views.—Our esteemed contemporary, the *Indiana Medical Journal*, thinks that we were unjust in criticizing Tolstoi's views of the medical profession, because we did not at the same time refer to the literary genius of Tolstoi. It is not the function of a medical journal to call attention to gifted works in general literature. Nor did we think it necessary to say of Tolstoi what must be every reading person's knowledge. We can advise our contemporary to read *Ketio*, if he is fond of noble writing. But, as regards the medical profession, Tolstoi is also "heroically wrong."

A Lady Physician, Dr. Hattie Allen, has been appointed Associate Professor of Medicine in the University of Michigan. Now we hope that Hattie will write herself Harriet.

For forty years Dr. Simon Pollak has occupied one chair in one place in the hall of the St. Louis Medical Society.—*Medical Review*. This quite beats the record of St. Simon Stylites, only St. Simon stood up, instead of sitting down.

A Testimonial for Soap.—We observe that a distinguished ex-President of the American Medical Association has written a testimonial in favor of a certain kind of soap. It is a little apart from the function of a great physician to indorse soaps; but he might have indorsed worse things. and we shall hope that the effect will be to give a fresh impetus to the use of commercial stearates among the numerous friends and admirers of our esteemed colleague.

Dr. C. S. Muscroft, of Cincinnati, O., died on May 1st, in the sixty-eighth year of his age.

The Medical Societies of the United States are said to number about six hundred and forty-eight.

Sulphonal—a New Hypnotic.—This substance is "diethylsulphondimethylmethan," an oxidation product of the union of ethyl-mercaptan with acetone, and has, therefore, the composition represented by the formula $(CH_3)_2 = C = (C_2H_5So_2)_2$. We owe its discovery to Professor E. Baumann, of Freiburg, and its therapeutical application, or, rather, some knowledge of its remarkable physiological properties, to Professor A. Kast, of Freiburg, who has a long article on the subject in the current issue of the *Berliner Klinische Wochenschrift* (April 16, 1888), in which he has nothing but praise for this new addition to the materia medica. The term "sulphonal" is due to a happy suggestion of Herren Fr. Bayer & Co., Elberfeld, who supply it. This substance crystallizes in large colorless tables, and is perfectly devoid of taste and smell. It dissolves in 18 or 20 parts of boiling water, in 100 parts of water at the ordinary temperature, and is easily soluble in alcohol or alcoholic ether. Employed medically, the drug has been given to 60 patients, and 300 observations of its effects were made (Professor Cramer gave it 200 times in the Marburg Lunatic Asylum). The results, almost without exception, were that the patients sank within from half an hour to two hours into a tranquil and sound sleep, lasting from five to eight hours, and awoke feeling perfectly comfortable. A few felt tired and sleepy next day. The digestion, pulse, and temperature were unaffected, and it is curious that no ataxy of any degree or kind was present, whereas this was the most prominent symptom in dogs after large doses. The ordinary dose for man is two grammes (half a drachm). Professor Kries has examined the effect of sulphonal on the blood-pressure, and has established the fact that in dogs, even after very large doses, the blood-pressure is not lowered. Poisonous doses in dogs, to determine the mode of death, caused severe convulsions, then, after a few hours, a heavy sleep, deepening to coma, and ending in death in about ten hours. Spectroscopic and microscopic examination of the blood revealed no alteration of its elements. Sulphonal appeared most efficacious in cases of sleeplessness in nervous subjects, but was given with benefit in all kinds of cases, including even cardiac valvular disease.—*British Medical Journal.*

A New Journal.—The *Revue Illustrée de Polytechnique Médicale et de Chirurgie Orthopédique* is the name of a new journal published in Paris, under the editorship of MM. Leblond and Chenet. It is the French edition of the well-known *Illustrirte Monatsschrift der Aerztlichen Polytechnik*, published by Dr. Beck, of Berne. We would be glad to see an English edition of this most excellent and instructive journal.

Leprosy is said by M. Besnier to be spreading rapidly, instead of dying out, as has commonly been supposed.

Cigarette Smokers will be interested to learn that 1,250,000,000 manufactured cigarettes are annually consumed in the United States. Probably as many more are made by the smokers themselves.

The Attendance at the spring lectures in the colleges of this city is about as good as usual.

Give Us the Quotation.—The physician who fails to have an eye to his fee, *first*, *last*, and *all* the time, will be left. Holy Writ tells us that the man who fails to provide for his family is worse than an infidel.—*The Southern Clinic.* We suspect that the foregoing is bad scripture as well as bad morals.

Dr. Joseph Ernst Hackl died in Toledo, Ohio, April 24, 1888, of laryngeal tuberculosis. He was born in Austria, August 22, 1847, and received his academical education at the University of Gratz. He graduated in medicine at the Starling Medical College in 1880. At the time of his death, and for five years previously, he was Professor of Physiology in the Toledo Medical College.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Thirty-ninth Annual Meeting, held in Cincinnati, O., May 8, 9, 10, *and* 11, 1888.

SECTION ON SURGERY AND ANATOMY.

Tuesday, May 8th—First Day.

Dr. Donald McLean, President, in the Chair.

The first session was called to order by The Chairman, who delivered the annual address, entitled

SOME THOUGHTS ON RETROSPECTIVE AND PROSPECTIVE SURGERY.

Particular reference was made to antiseptics, anæsthetics, and abdominal surgery. To anæsthetics the greatest credit was given, as they not only relieve the pain of the patient, but remove the timidity and terror of the operator. Too much value has perhaps been attached to antiseptics, and they may come to be considered a nuisance. The teachings of Mr. Lister have, however, induced strict cleanliness at least, and, whatever there may be in the germ-theory, there is much to be thankful for in Listerism.

Chloroform, as a rule, is the best anæsthetic, yet there is reason to expect a new and better one in the near future.

An instrument for the administration of anæsthetics was displayed and described.

Mention was made of the microscope in surgical diagnosis and differentiation of tumors, pus, etc.

Electricity in suitable cases is a powerful agent for good, but, like others, is much abused; it offers one of the best methods in stricture of the urethra. An interesting case of such kind was reported cured by electricity. Electrolysis in the treatment of nævus is preferable to other remedies.

Esmarch's bandage and the animal ligature were also referred to. By their use, the speaker said, vessels as large as the femoral may be safely tied.

Joint diseases are now treated by rest, pressure, and resection, even when the disease has passed far beyond the articulation.

The many appliances that have been in use for the

TREATMENT OF FRACTURES

were passed over with the mention of but a few. Plaster of Paris was considered the best of all splint materials. Passive motion is beginning to be used earlier than in former times.

Lithotomy is perhaps being rapidly superseded by lithotrity, but the speaker strongly favored the former.

Dr. Henry Hollingsworth Smith, of Philadelphia, presented a paper on

THE APPENDIX VERMIFORMIS: ITS FUNCTIONS, PATHOLOGICAL CHANGES, AND TREATMENT.

He characterized the appendix as a "singular little organ, singularly placed, physiologically useless."

After a brief anatomical description of the appendix, the speaker referred to its anomalies, and then to its diseases. An early diagnosis in all cases of disease of this organ is of the utmost importance, yet it must often be made by exclusion only.

The prognosis of these affections was always grave.

In the treatment, he usually began with five-grain doses of calomel, repeated until twenty to thirty grains are taken.

Morphia was given hypodermically for the pain. Later in the course of the disease he employed saline purgatives, aided by palpation, to increase peristalsis. If all these measures failed the only recourse left was to operate.

Dr. T. G. Morton, of Philadelphia, said that one ought always to suspect disease of the appendix in any affection in which the symptoms pointed to the ileo-cæcal region as the seat of inflammation. He was strongly in favor of operation in these cases, believing that the general principle held good to evacuate pus whenever it was present, and to attack the seat of its formation in order to cut short the suppurative process when possible.

Wednesday, May 9th—Second Day.

Dr. L. S. McMurtry, of Danville, Ky., reported a case of

TYPHLITIS WITH PERFORATION; LAPAROTOMY; RECOVERY.

The patient was a physician who was subject to attacks of colic, for the relief of which morphine, hypodermically, was used. After a time tenderness was complained of, and a tumor was discovered in the iliac region. This was followed by hemorrhage from the bowels, vomiting, and tympanites, indicating perforation.

An operation was urged, and allowed. The appendix was found to be normal, but the cæcum was gangrenous in spots, with a perforation through which extravasation of fæces had taken place. The edges of the perforations were trimmed, and the openings were made elliptical in shape and were closed by suture.

Recovery.—The patient was a member of the American Medical Association, and was present at the meeting. The speaker said that he had the pleasure of reporting

THE ONLY CASE OF SUCCESSFUL LAPAROTOMY

for the relief of non-traumatic perforation of the cæcum. He maintained that one ought to operate early in these cases, and should not rely on opium.

Dr. Edward Andrews, of Chicago, said that the most interesting point to determine is, in what cases to operate, as there is often great difficulty in making a correct diagnosis. He added that there is much risk in operating in these cases, as there is no time to make preparation, as in ovariotomy. In the latter operation the mortality is one in ten.

There is little chance for recovery in perforation with effusion into the peritoneal cavity, but good prospects when there is simple perforation.

Dr. Gross, of Philadelphia, thought that the early operation was generally best, and that in a walking case of typhoid fever with perforation he would operate. If we wait, the patient dies; if we operate, there is a fair chance to save life.

Dr. Nelson, of New London, Conn., thought there was but little more danger from the use of the knife than from the aspirator.

The line of incision should be over the point of rupture.

The election of officers was then held, with the following result: *Chairman*, Dr. N. P. Dandridge, of Cincinnati; *Secretary*, Dr. M. O. Roberts, of Louisville.

Dr. Charles B. Penrose, of Philadelphia, read a paper on

INTESTINAL OBSTRUCTION IN ITS SURGICAL ASPECTS.

He said that operations are too often delayed by expectant treatment—opium, massage—and that it would be far better to make an exploratory laparotomy.

Enterotomy or colotomy is rarely desirable. The primary incision should be median, as it gives better opportunity to explore the abdominal cavity.

If the bowel is much distended by gas, it should be incised longitudinally, emptied of its contents, and closed by suture.

For the relief of obstruction, the plan recently suggested, of

INTESTINAL ANASTOMOSIS,

was mentioned but not advised. Resection, with the temporary formation of an artificial anus, the speaker thought, would offer the best chance for a good result. Both ends of the bowel should be stitched to the opening, thus giving more surface for the absorption of nutrition, as nourishment can be given by the mouth, and a special preparation can also be injected into the lower portion of the bowel. Especial value was attached to continual irrigation of the abdomen.

Dr. N. Senn, of Milwaukee, read a paper on

RECTAL INSUFFLATION WITH HYDROGEN-GAS AS AN INFALLIBLE DIAGNOSTIC MEASURE

in ascertaining the existence of visceral injury of the gastro-intestinal canal in penetrating wounds of the abdomen. The existence of any wound in the bowel where there is extravasation into the peritoneal sac has always been considered fatal unless laparotomy is done. Punctured penetrating wounds are less serious than gunshot wounds. In order to determine some means by which a clear diagnosis could be made, he had undertaken a number of experiments to find some innocuous gas which could be injected per rectum until the bowel was sufficiently distended for the gas to reach the wound and appear externally.

The first experiment showed that hydrogen-gas could be made to pass the entire length of the gastro-intestinal canal from the anus to the mouth. In a man a pressure of from one-third to two pounds is sufficient to effect the passage of the ileo-cæcal valve. Inflation through the mouth is only used to diagnose wounds of the stomach, as the gas does not easily pass the pylorus.

Hydrogen-gas is perfectly innocuous and unirritating, and is rapidly absorbed when injected into any serous cavity or into the connective tissue.

All that is necessary in using the gas is a rubber balloon holding sixteen litres. Inject gradually. The method not only establishes the diagnosis, but locates the wound of the bowel without tedious handling, and demonstrates whether there be more than one perforation.

A pistol-wound of the abdomen was produced in a dog, and the perforation of the bowel diagnosed, demonstrated, and the number determined by this method.

Dr. P. S. Connor, of Cincinnati, classified obstructions as acute and chronic. Acute cases should be operated upon after a few hours, if they do not yield to other treatment.

He agreed with a former speaker that the operation was not devoid of danger, as was claimed by Dr. Price.

We can sometimes gain much valuable information by opening the bladder, but we cannot always cure the patient by that means.

Dr. L. H. Weeks, of Portland, said that laparotomy is not necessary in every case, but we must nevertheless not put off the operation until it is too late. No physician of to-day should let a patient die from internal obstruction any more than he would from external strangulated hernia.

Dr. Marcy, of Boston, then read a paper on

THE SURGICAL ADVANTAGES OF THE BURIED ANIMAL-SUTURE,

and its adaptability to special purposes. He reviewed at some length the history of this procedure, and also suggested that the operating-room be made aseptic by the use of oxygen; it is refreshing, he said, to the operator, and safer for the patient under ether. He spoke of iodoform collodion painted over the part after the operation is finished, and recommended its use. The future of sutures, he maintained, depends upon the strict carrying out of antiseptic measures.

Thursday, May 10th—Third Day.

Dr. Elmer Lee, of St. Louis, presented a communication on

DRY MEDICATION IN THE TREATMENT OF THE URETHRA AND BLADDER.

There are plenty of drugs, he said, that we can use for this purpose, but the question is, which shall we select and how shall we use them? It was necessary to employ alkaloids, which were pure chemicals in a condensed form. These were best applied in the form of soluble granules made with pure cane-sugar. It was, of course, necessary to apply these in just the right place, for which purpose an instrument was required. The speaker exhibited the granules and instrument employed by him.

Dr. D. S. Campbell, of Detroit, read a paper on

ELECTROLYSIS IN THE TREATMENT OF NASAL AND PHARYNGEAL NEOPLASMS.

He had employed the method in a number of cases, and had found it superior to any other plan of treatment.

Dr. H. Landis Getz, of Marshallton, Ia., exhibited an

ANTISEPTIC SURGICAL CABINET.

It consisted of square frames covered with gauze, wet with a bichloride solution, forming three sides and the roof of a square tent, the window of the apartment forming the fourth side. The window was slightly lowered, and the opening filled by a strip of wood. Through a hole in this wood a tightly fitting soft rubber tube was passed, to which a mouth-piece was attached, thus allowing the patient and the operators to take an occasional inspiration of fresh air. The head and shoulders of the patient are brought out through a closely fitting aperture in the wall of the tent opposite the window. The walls of the tent are kept constantly moistened with bichlorate solution from an atomizer. Operations must often be performed when there is no chance to make the apartment aseptic, in which cases, the speaker thought, this device would prove to be of much value.

Dr. Thomas P. Davis, of Pittsburg, read a paper on

GRADUAL DILATATION OF ŒSOPHAGEAL STRICTURES.

He reported several cases of stricture of the œsophagus caused by swallowing lye. He urged early and very gradual dilatation. He also suggested that measures be taken to suppress the indiscriminate use of concentrated lye, owing to the frequent deaths resulting from the accidental swallowing of this caustic.

Friday, May 11th—Fourth Day.

Dr. Joseph Ransohoff, of Cincinnati, read a paper on

THE CÆCUM AND APPENDIX: THEIR RELATIONS IN HEALTH AND DISEASE.

The speaker considered the subject in its anatomical and physiological aspects, since here, as elsewhere, such knowledge is a prerequisite to the understanding of vital processes, normal and abnormal. He said that the topography of the cæcum, the vermiformis appendix, and the ileum is misunderstood not alone by the profession as a body, but by most anatomical writers. All agree that the cæcum is a blind pouch about three inches in diameter, two and a half inches in length, and is the widest part of the intestine. It is generally agreed that the cæcum is covered by peritoneum in front and on its sides, and that the posterior portion is connected to the iliac fascia by loose connective tissue. The fact is, however, that the cæcum is, with rare exceptions, completely surrounded by peritoneum from the ileo-cæcal valve to its apex. This was discovered as long ago as 1849, from the examination of 160 bodies. In 2 out of 63 bodies which the speaker had examined, he had found the cæcum invested only in front and laterally.

On the postero-lateral aspect of the cæcum, about an inch from its base, springs the appendix. This is not such a wanderer as is often supposed, but usually lies behind the cæcum, and can be seen only by drawing the cæcum aside. It points upward to the left, toward the spleen. In only seven of the examinations made did the speaker find the appendix in part a pelvic organ. Its average length is four inches; its diameter, that of a goose-quill. The appendix is rarely straight in its course. One instance of its complete absence was noted by Bartholin. Since it is nowhere attached to the abdominal wall and, like the cæcum, everywhere covered by peritoneum, abscess of the ileo-cæcal fossa must be limited, and perforation must involve the peritoneum.

If the cæcum and appendix have a function, it can only be inferred by comparative studies. In man the chief function of the cæcum is absorption. The appendix has even stronger facilities for absorption, hence its contents are always of a firmer consistency.

A probable function of the appendix is the secretion of mucus. Like the tonsil, the appendix is a lubricator.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Tuesday, May 8th—First Day.

Dr. Ely van der Warker, President, in the Chair.

Dr. Henry O. Marcy, of Boston, read a paper upon

EXPLORATORY LAPAROTOMY.

Owing to the advances which had been made in recent times in surgical technique and in antiseptic methods, the question of danger has been practically excluded in a consideration of laparotomy. Although there have also been great advances in the clinical differentiation of abdominal diseases, cases are nevertheless constantly occurring in which a correct diagnosis can be arrived at only as a result of operation. And the experience of nearly every practitioner offers abundant illustration of the uncertainty which marks the fatal progress of cases of intestinal obstruction, extra-uterine pregnancy, etc.

Dr. Marcy entered a vigorous protest against the still too common method of waiting and treating symptomatically conditions in which there was the greatest danger to life, and urged a wise consideration of the measures of exploration. He related a series of eleven cases in his own practice, in which exploratory laparotomy had been performed. In no instance did death result, and in two of the cases the knowledge acquired as a result of the operation furnished indications for treatment leading to a cure.

Dr. S. C. Gordon, of Portland, Me., reported three cases of

VAGINAL HYSTERECTOMY FOR CANCER.

The speaker stated that the views of the profession were now in favor of the doctrine of local origin of cancer, and that the consequent practice of surgeons was early operation and entire removal of the organ or part affected. He also claimed that the uterus is no exception to the rule, and if the case is early seen and the uterus alone is involved and movable, the only rational operation is complete removal.

He believed the mortality would not be as great as after laparotomy, inasmuch as drainage acts as an important aid to recovery. Statistics already show as good, or better, results as regards mortality, and the operation is yet in its infancy. Frequent operations by experts will reduce the death-rate materially. Death is certain if the case is left to the natural course. There is every reason to hope more from complete than from partial operation.

Two of the cases recovered without any alarming symptoms. The third one died from obstruction of the intestines.

Dr. William C. Wile, of Danbury, Conn., exhibited a

RETENTION APPARATUS

for supporting the legs in operations about the perineum. It was well adapted to the purpose for which it was devised, and enabled the operator to dispense with the services of two assistants to hold the legs and feet of the patient out of the way.

Dr. W. W. Jaggard, of Chicago, read a paper on the occasional

RELATION OF ENDOMETRITIS TO THE VOMITING OF PREGNANCY.

He reported the case of a woman, aged twenty-nine, who had given birth to four living children, and had had two miscarriages. When the patient was seen she was in the twentieth week of pregnancy, and was suffering from constant vomiting, the slightest muscular exertion occasioning an exacerbation of the trouble. Abortion was induced, and it was found that endometritis existed, which the history of the case showed to be of long standing. The vomiting ceased immediately upon the termination of gestation, and the speaker believed that it was reflex in character, starting from the peripheral irritation of the inflamed endometrium.

Dr. Marcy had carefully studied a number of these cases, and believed that the true pathological condition was one of continued activity and growth of the uterine glands, which should normally atrophy as the placenta becomes developed. If this explanation were correct, the problem of treatment was greatly simplified. The blighted ovum must be removed and the uterine mucosa regenerated. Since the fœtus can hardly survive long enough to arrive at a viable period, early abortion should be the rule, and the case should not be allowed to progress to such an extremity as to jeopardize the life of the mother.

Dr. Joseph Price, of Philadelphia, presented a communication on

A SYSTEM OF FREE NURSING,

as it existed in Philadelphia. The organization was known as the Visiting Nurse Society. Its objects were to furnish visiting nurses to those otherwise unable to procure skilled attendance in time of illness, to teach cleanliness, and the proper care of the sick. The society was established two years ago, and the staff now consists of seven nurses and assistants, and one maternity nurse. During the present year these nurses have attended to about two hundred cases, one hundred of which were surgical. The speaker urged the adoption of this system by other communities.

Dr. William Goodell, of Philadelphia, read a paper entitled

THE NERVOUS RECTUM.

Hysteria is closely allied to insanity, and as the latter frequently consists of a single delusion, while the mind remains clear on all other subjects, so hysteria often exhibits itself chiefly by some localized disorder. It becomes, as it were, a sort of

MUSCULAR INSANITY.

The muscles most liable to become hysterical are the circular ones constituting the inlets or outlets of the hollow viscera. In one form, localized in the rectum, spasm of the sphincter occurs, and the symptoms mimic those of anal fissure. Defecation gives rise to great suffering, and a painful throbbing, which may continue for hours, follows the completion of the act. Patients thus afflicted often become victims of the opium habit. The seat of the pain may be higher up in the rectum, and the attacks may recur with some appearance of periodicity. In other cases there is a throbbing pain when the rectum is loaded, and the act of defecation causes a sickening sensation. The two last-mentioned forms are often dependent on prolapse and tenderness of the ovaries. Sometimes the tonic spasm of the sphincter is so pronounced that it can be overcome only by enemata. In some cases of nervous rectum there may be no pain, but the necessity of going to stool occurs at most unseasonable times, and is occasioned by the most trivial causes.

A disease which is in a measure peculiar to emotional women of a high degree of intelligence is

FOLLICULAR COLITIS.

This may be considered under the general heading of nervous rectum, although its pathology is as yet by no means well understood.

Dr. Goodell said that he knew of nothing which would cure this condition unless the general nervous prostration were first overcome. Various remedies, applied in the form of enemata or suppositories, had, however, a soothing local effect. Among these might be mentioned suppositories of belladonna, iodoform, or antipyrine, and injections of thin starch, flax-seed tea, hamamelis, lime-water, or carron-oil. Opium should not be used, because of the danger of the habit becoming established. The speaker's favorite remedy was a sugar-coated pill, composed of one-fortieth grain of arsenious acid, one grain each of dried sulphate of iron and extract of sumbul, and two grains of assafœtida. Blaud's pills were also useful. If a malarial element were present he prescribed a mixture of one part of Fowler's solution to nine parts of the sirup of the iodide of iron. Of this ten drops were given after each meal, increased by a drop at a time to thirty drops, decreased at the same rate to the original dose, and then discontinued. For sudden paroxysms of rectal pain in the hysterical condition, nothing was so good as antipyrine in five-grain doses, or hyoscine hydrobromate in the dose of $\frac{1}{125}$ grain. The rest-treatment is useful when it is practicable.

WEDNESDAY, MAY 9TH—SECOND DAY.

Dr. L. H. Dunning, of South Bend, Ind., reported a case of

DOUBLE UTERUS AND VAGINA.

and presented a review of the literature of uterine malformations.

He found the uterus bicornus to be the most frequent malformation. When the ovaries were normal and a small amount of the uterine mucosa was present, menstruation usually occurred. Fifty per cent. of the pregnancies in cases of uterus bilocularis resulted in abortion. When a thick vaginal septum existed, if it were recognized before the occurrence of pregnancy, it should be removed. He thought the best plan was to excise the septum and secure the edges of the vaginal mucous membrane with catgut, in order to avoid, as far as possible, the formation of cicatricial tissue in the vagina.

Dr. William H. Taylor, of Cincinnati, reported two cases which he had seen in his practice in the past year. In one of the cases there was a uterus bicornus and a vaginal septum.

THE CHILD STRADDLED THE SEPTUM

and tore it away. The labor was not followed by any bad consequences. The second case was one of double vagina.

Dr. William Goodell, of Philadelphia, related a case of uterus bicornus which he had diagnosed as one of extra-uterine pregnancy, and had lectured upon it for an hour before his class at the University of Pennsylvania. He had watched the case closely from the beginning, and his mistake had convinced him of the ease with which errors in diagnosis could be made in these unusual cases.

The election of officers resulted in the choice of *Chairman:* Dr. W. H. Wathen, of Louisville; *Secretary:* Dr. A. B. Carpenter, Cleveland, O.

Dr. F. H. Martin, of Chicago, read a paper on the

VALUE OF GALVANISM IN THE TREATMENT OF FIBROID TUMORS OF THE UTERUS,

according to Apostoli's method, of which the following is a summary:

1. A means of generating a continuous current of electricity of steady and uniform character, that can give an actual current strength, through a resistance of 200 ohms, of 500 milliampères, is necessary to obtain all the benefits of this treatment.

2. Fibroid tumors of small size can be completely absorbed by the proper application of strong currents of galvanism.

3. Hemorrhages from fibroid tumors can be promptly cured by the local coagulating effect of the positive pole applied to the interior of the uterus. Severe neuralgias, so often accompanying these troubles, can invariably be relieved by three or four applications of this treatment.

4. When the cervical canal cannot be entered by any form of intra-uterine electrode, flexible or otherwise, after repeated trials, a negative galvano-puncture should be made into the presenting part of the obstructing mass of the tumor and an artificial canal opened, which is to take the place of the impermeable uterine canal in all subsequent treatments.

5. The intra-uterine electrode should in all cases be negative, unless there is hemorrhage or excessive leucorrhœa, when the positive pole is required. The same patient may, however, present symptoms demanding the use of both poles at successive operations.

6. The strength of the current should depend entirely upon the area of active surface of the internal electrode, and should be 25 milliampères for each square cubic metre of active surface in actual contact with the endometrium. If more is used, the concentration of the current will be sufficient to cause troublesome cauterization. If less is used, the concentration at any one point will not be enough to cause the necessary coagulation for checking hemorrhage.

7. The duration of each sitting should be five minutes when the maximum current required is employed.

8. The number of operations is necessarily dependent upon, and influenced by, the result to be accomplished. A severe hemorrhage can be checked, and relief to the symptoms often accomplished, by four or five séances, while a general reduction of the tumor necessitates many operations, varied, of course, according to the size and location. In some cases of large multiple tumors a relief of the symptoms, or a symptomatic cure, must be accepted as a substitute for an actual cure.

9. The operation should be intermenstrual, if possible, but if the hemorrhage is continuous, it will be necessary to operate during the flow. The séances may be held every day, with the system of concentration adopted that enables one to attack different portions of the canal at succeeding treatments, or they can be given with advantage as seldom as once a week.

10. Since the adoption of the flexible intra-uterine electrodes and Dr. Apostoli's method of vaginal galvano-puncture, extra-uterine puncture should be practised, if at all, only as a last resort.

11. Galvano-puncture needles and the internal electrodes should be constructed of material that is not injured by coming in contact with strong carbolic acid, or 1 to 1,000 bichloride of mercury solution. All electrodes for internal use should be thoroughly scrubbed with a nail-brush and soap and water after each application, and allowed to remain in one or another of these standard antiseptic solutions until they are to be employed again, when they should be washed in a weaker solution of the same before using. Before a vaginal puncture is made, the vagina should be thoroughly wiped out with a 1 to 3,000 bichloride solution.

12. There is no excuse for any percentage of mortality in the proper application of this treatment. While Dr. Apostoli has had 2 deaths in 275 cases, he candidly admits that they were due to avoidable accidents, and should not be considered as legitimate consequences of the operation.

13. In experienced hands, and by the adoption of the present means of concentration, the most delicate and

sensitive patient can receive, without experiencing any severe discomfort, all the benefits to be derived from this valuable treatment.

Dr. Newman, of New York, thought that indiscriminate piercing might do much harm. A man must know where he is, and must have the proper instruments.

Dr. Marcy, of Boston, thought the subject one of the most important of the new departures. At the last International Medical Congress a whole day was given up to it. He had used the treatment during the past winter with much, though not unqualified, success.

Dr. A. B. Carpenter, of Cleveland, followed with another paper on

APOSTOLI'S METHOD.

He thought it very necessary to commence with a small dosage of galvanism, and then gradually increase it. Rest was also very necessary. He required his patients to remain an hour in the office after treatment. He had found that his patients were stimulated by the treatment, and were inclined to visit their friends and talk too much unless controlled. The speaker exhibited the apparatus employed by him, which created much interest.

Dr. L. S. McMurtry, of Danville, Ky., reported a case of

TYPHLITIS WITH DOUBLE PERFORATION OF THE CÆCUM

and peritonitis, in which laparotomy and suture of the gut were followed by recovery. The patient was a physician (who was present), who was attacked with typhlitis in January last. Symptoms of peritonitis supervened, and, when seen by Dr. McMurtry, he was in collapse, with serous vomiting and bloody stools. Abdominal section was at once performed, the incision being made on a line two inches to the right of the umbilicus and continued obliquely toward the pubes. The peritonitis was limited, but bore evidences of being recent, severe, and spreading. The vermiform appendix was unaltered, but two gangrenous perforations were found in the cæcum. The sloughing edges of the openings in the gut were trimmed away with scissors, and united with silk sutures, applied after Lambert's method. The peritoneum was cleansed, and a rubber drainage-tube inserted. The patient made a rapid and complete recovery.

Dr. McMurtry called attention to the fact that the treatment of non-traumatic perforation of the intestines by abdominal section is of recent date. The first operation of this kind was reported in 1883, by Mikulicz, for perforation of the vermiform appendix. The case terminated fatally. In June, 1887, Weir was able to collect only fifteen cases in which laparotomy was done for perforation of the intestines not due to traumatic causes. Of this number, nine were cases of perforation of the appendix. Two more have been reported since Weir's paper appeared, making a total of eleven cases of laparotomy for perforation of the appendix, with three recoveries. Only one case of laparotomy for peritonitis due to perforation of the cæcum has been reported, the perforation having been discovered only at the autopsy. The case here reported was the first one recorded of peritonitis, caused by perforation of the cæcum, treated successfully by abdominal section.

The speaker called attention to the importance of distinguishing between pericæcal abscess (perityphlitis), where the seat of inflammation and suppuration is extra-peritoneal, and cases of perforative peritonitis. He made a plea for more frequent resort to

EXPLORATORY INCISION,

which he thought superior to aspiration, and involving less danger of peritoneal infection. As soon as the diagnosis of perforative peritonitis had been made, the only hope of recovery lay in an immediate resort to laparotomy.

Dr. Thomas Keith has removed from Edinburgh to London.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE COLLEGE OF SURGEONS—A SUCCESSFUL OPERATION FOR CEREBRAL ABSCESS—THE DISCRIMINATION OF LARGE AND SMALL VALVULAR LESIONS OF THE HEART—LOOSE BODIES IN THE KNEE-JOINT—THE ROYAL MEDICAL BENEVOLENT COLLEGE—THE LATE PROFESSOR DE CHAUMONT.

London, April 21, 1888.

Affairs at the College of Surgeons continue pretty much in *statu quo.* No steps have been taken, as yet, toward meeting the wishes of the members. The ruling body seem to possess a great deal of inertia, and are apparently not to be roused by any outside pressure short of compulsion. One trifling reform has just been initiated by them, but one scarcely deserving of notice. Attention having been directed to the scanty attendance upon the college lectures, the Council have apparently felt it incumbent upon them to pay some attention to the matter. As the result of their lucubrations the lecture hour has been changed from four to five, which latter hour may prove somewhat more convenient to busy practitioners thirsting for college lectures.

At the Medical Society of London, on Monday last, Mr. Damer Harrison, of Liverpool, narrated a case in which he had successfully operated for cerebral abscess. The patient was a boy of fifteen, who had received a severe blow on the left side of the head eleven years previously. A wound was caused from which bone was removed, but no severe symptoms then followed. A year ago, however, twitchings in the right arm were observed. These were confined to the flexors of the wrist, the biceps, and the deltoid. Eight days before he was admitted into the hospital he had received a blow on the *right* side of the head. Three days later convulsions occurred on the right side of the body, first in the arm, and then in the face and leg. Loss of power ensued on the right side, especially marked in the right arm. Similar convulsive attacks followed in the succeeding four days. They were accompanied by giddiness and pain in the head, but by no loss of consciousness. The pain in the head increased and the paralysis became more marked, especially in the face and leg. Vomiting occurred. The intellect was impaired. Vision in the right eye was also affected. The reflexes on the right side were diminished. No ophthalmoscopic examination could be made. A diagnosis was made of cerebral abscess situated in the motor region of the cortex. An operation was determined on, and a circle of bone removed with the trephine, the centre of the trephine-hole being placed three-quarters of an inch in front of the fissure of Rolando, as determined by Thane's method. As there was no bulging of the dura mater it was not incised at once, but the wound was kept open. At the end of four days, the symptoms having become more urgent, a crucial incision one inch in extent was made through the dura mater. A vertical puncture was then made in the brain with a tenotomy knife to the depth of an inch and a quarter. A drop of pus exuded, and an incision an inch in length was then made, along which about four drachms of fetid pus rapidly flowed. The abscess-cavity was washed out with corrosive sublimate lotion, and a horsehair drain inserted. The patient was allowed to get up a month after the operation, and could walk about with assistance. At the present time the patient was perfectly well, the only noticeable symptom being the slightly feebler grip of the right hand as compared with the left.

Mr. Barker adverted to the immense difficulty of examining patients' eyes just at the time when such examination possessed the greatest interest. Dr. Beevor thought the tendency of all these cases of cerebral abscess was to confirm Dr. Ferrier's view as to the cerebral centres. He remarked that abscess, being of rapid growth, might not give rise to optic neuritis, whereas in tumors this was generally present. Dr. Money observed that their experience at University College Hospital, in cases of suppuration of the brain, was that the temperature was invariably subnormal, an opinion which was confirmed by Dr. Herringham.

Dr. Milner Fothergill then read a paper on the discrimination of large and small lesions in cases of cardiac valvular disease. He referred to the evolution of the heart from a mere pulsatile muscular sac, and said that nature compensated a valvular injury by falling back upon the primitive form of heart—the muscular sac. As in evolution valves economized muscular energy, so in dissolution an injury to the valvular mechanism of the higher heart was compensated by muscular growth—a development of the early lower heart—spoken of as compensatory hypertrophy. We realized that we could do nothing for a valvular lesion; our hopes centred on the primitive muscle. If by rest and good food, with cardiac tonics, we could aid nature's attempt to develop the primitive heart, so far so good. A small lesion was easily compensated, and the compensation easily maintained for years. With a large injury, complete compensation was unattainable, and such compensation as was possible soon wore out. It was consequently important to measure the extent of valve-mutilation, and from that to calculate the chances of the patient. A murmur revealed the existence of valvular injury, but was dumb as to its extent. To ascertain that we must examine the case physiologically (especially in mitral lesions) and test the effect of effort. With a small lesion the patient could run, but not very far; with a moderate lesion he could walk on the flat, but not get up hills easily or run; with a large injury all effort would be distressing. In strict proportion to the extent of the lesion was the organism crippled and life shortened.

A somewhat animated discussion took place at the Pathological Society, a few evenings since, on the subject of loose bodies in the knee-joint. Mr. Shattock showed a specimen of a rare form of foreign body which had been removed. It was discoidal in form, and invested by a thin capsule of connective tissue continued into the falciform synovial fold on the right side. At first sight it looked like an overgrowth of fat, such as often occurred in the alar ligaments, but histological examination showed a faintly stained structure with collections of reddish-brown granular pigment in trabeculæ, variously arranged. It was evidently the result of an old hæmatocele into the alar ligament from some injury. Mr. Bowlby referred to a specimen in St. Bartholomew's Hospital Museum, of a hæmatocele which had formed in the knee of a healthy man after injury, and formed a loose body in the joint. It had been removed by operation. He then showed a specimen from one of Mr. Morrant Baker's cases, of a loose body starting from a torn fringe of synovial membrane. Another specimen showed portions of the semilunar cartilages which had been found loose in the knee-joint after injury, and were removed by operation. A jar was also shown containing four hundred and fifteen loose bodies removed from the knee-joint of a man who had suffered from rheumatic fever. They were composed throughout of hyaline cartilage, and only four or five of them had pedicles. A case was mentioned in which, without any history of injury, a loose body was found in the left knee of a lad of eighteen. It was removed by operation, and turned out to be a small portion of cartilage detached from the surface of the femur. The patient made a good recovery, but returned a year later with a similar body in the other knee. The specimen was shown. Mr. Godlee mentioned that he once had the opportunity of removing a very peculiar body from the knee-joint. It had been diagnosed as a loose cartilage, but turned out to be a broadly pedunculated mass growing from the internal ligament. Mr. Clutton referred to a case in which he had removed a loose body from a knee-joint in a boy, and, two years later, another from the opposite knee. Professor Humphrey discussed the possibility of quiet necrosis of the cartilages, leading to suppuration, and observed that the presence of calcareous matter was a difficulty in connection therewith. Up to the present time, no instances had been adduced of a portion of bone or cartilage being chipped off and forming a loose body in the joint, except the case reported by Mr. Simon. Mr. Howard Marsh said quiet necrosis was a rare process, but it certainly did take place, and he thought that of all structures articular cartilage would be the most likely site for it to occur in. Sir James Paget remarked that in his own paper on quiet necrosis he was referring to the process in osseous tissue only, and the credit of first describing the process in cartilage belonged to Teale.

A highly successful festival in aid of the Royal Medical Benevolent College was held a few days since. This is an institution far less widely known than it deserves to be. Its functions are both educational and eleemosynary. In its former capacity it receives two hundred resident pupils, of whom fifty are foundation scholars, and receive a sound education free of all expense. The remainder pay about fifty (or, if not sons of medical men, seventy) pounds annually. There are also fifty pensioners (twenty-four of these being resident), who must be either medical men, or the widows of medical men, in reduced circumstances.

The death is announced of Dr. De Chaumont, Professor of Military Hygiene in the Army Hospital Medical School. Dr. De Chaumont was a well-known worker in the field of sanitary science, and assisted the late Dr. Parkes in his labors at Netley, finally succeeding him in the professorial chair. He edited the last edition of Dr. Parkes' well-known work on hygiene.

OUR PARIS LETTER.

DR. NACHTEL AND THE AMBULANCE SYSTEM IN PARIS—PRODROMIC SIGNS OF LOCOMOTOR ATAXIA.

Paris, April 20, 1888.

There is at last some hope that the system of ambulance proposed some time ago by Dr. Nachtel will soon be adopted in Paris. Authorization has been granted by the Board of Public Assistance to unite, by special telephonic lines, the St. Louis Hospital with twenty-seven warning-posts placed in different quarters of Paris, within a perimeter of eight kilometres (about five English miles), in the chemists' shops and in the bureaus of police. When an accident happens in the public streets, notice will be immediately transmitted to the St. Louis Hospital, where a staff of internes are in constant attendance. The ambulance wagon set apart for the purpose, which is always ready with horses harnessed, will start at the first signal, and the patient will receive medical or surgical aid in from three to ten minutes, according to the distance. The funds collected by Dr. Nachtel are estimated sufficient to give this system a year's trial, after which it will be decided as to whether it shall be permanently adopted or not.

M. Franck communicated the report of a special commission which was charged to examine the work of MM. Henrion and Charles Richet. This work was undertaken to determine the difference of activity in the exchange of gases which takes place in the lungs during natural sleep and hypnotic sleep. It results from these experiments and from the observations of the authors, as was confirmed by the commission, that a diminution of activity and a sort of semi-asphyxia are produced under the influence of hypnotism. This state explains the many phenomena, more or less strange or surprising, which accompany artificial sleep: Slackening of the respiration, weakness, and even the apparent disappearance, of the beats of the heart, general coldness of the body, pallor of the face, lethargic aspect, etc.

At a recent meeting of the Société de Biologie Dr. Galezowski read a paper on the prodromic signs of locomotor ataxy, two of which had particularly attracted his attention during the last few years—these are paralysis of the muscle of accommodation and anæsthesia of the peri-orbital region. He stated that within the last six years he noticed the existence of these two phenomena in a certain number of patients who have since become undoubted ataxics, although at the time they were first examined nothing led him to foresee the appearance of this malady, excepting a weakness of the rotulian or patellar reflex, which was established among some of the patients by Professor Charcot. The paralysis of the muscle of accommodation which Dr. Galezowski observed in his patients was not accompanied by mydriasis, nor paralysis of any of the other muscles supplied by the third pair of nerves. As this paralysis is, moreover, always localized in one eye only, it caused no trouble whatever in the vision whenever the patient looked with both eyes; while the paralysis of accommodation which succeeds diphtheria is, on the contrary, always binocular. That which presents itself after certain contusions of the eye is not accompanied by anæsthesia of the peri-orbital region. The same is the case with that which occurs in the course of syphilis. The author therefore believes that this paralysis, when it is unilateral, and when it is accompanied by anæsthesia of the peri-orbital region, constitutes a precursory pathognomonic sign of locomotor ataxy. Dr. Brown-Séquard observed that, as it has been shown that ninety-eight per cent. of cases of ataxy have a syphilitic origin, he saw no reason why the ocular troubles brought to notice by Dr. Galezowski would not also be of a syphilitic nature. To this Dr. Galezowski replied that, while it was admitted that in the majority of cases the ataxy is of a syphilitic nature, he could affirm that, of 1,016 cases of atrophy of the papilla which he had observed, he counted about eight hundred ataxics, and that, of these 800 cases, more than half had a syphilitic origin. It is, therefore, absolutely established that, in a great number of cases, atrophy of the papilla, in ataxic patients, is of syphilitic origin; whence this practical conclusion, that the ocular lesions of syphilis ought to be treated with great energy as soon as they make their appearance, in order to prevent atrophy of the optic nerves. To a remark made by Dr. Dumontpallier, that the paralysis and the anæsthesia of the peri-orbital region may equally be met with in hysterical patients, Dr. Galezowski responded that, in the latter, the paralysis of the ciliary muscle was always accompanied by mydriasis.

At a subsequent meeting of the same society, Dr. Gellé reported the case of a female patient who was many years affected with paralysis of the right vocal cord, due to the presence of a tumor on the course of the recurrent nerve, and who was suddenly seized with complete deafness. Examination of the ear elicited no appreciable lesion whatever. Thinking that he had to do with a dyscrasic condition, Dr. Gellé had the patient's urine examined, and a slight quantity of albumen was found in it. There was no œdema present, and the patient did not complain of any giddiness, either spontaneous or provoked. Fifteen days later œdema of the legs showed itself. The patient remained deaf for eighteen months afterward, and died with all the classical signs of albuminuria. The author concluded his report with the remark that this case is interesting in many points of view: It proves, in the first place, that the sudden deafness, without any lesion of the auditory apparatus, may be an accident of albuminuria in its incipient stage. This deafness is incurable.

A stomatological society for the scientific study of affections of the mouth and teeth has been founded in Paris. This society will be composed of the members who have founded it, and other national and foreign members. Medical men desirous of becoming members are requested to apply to Dr. Magitot, 8 Rue des Saints-Pères, Paris.

Dr. Baader, editor of the *Correspondenzblatt fur Schweitzer Aerzte*, died recently in Basle.

PROFESSIONAL QUACKERY.

To the Editor of The Medical Record.

Sir: I saw to-day a reprint from the *American Journal of Obstetrics* of an article on laparotomy, which the author had sent to the patient of another physician, with the apparent intention of encouraging the recipient to apply to him for the removal of her ovaries. I say *apparent*, for the reason that numerous paragraphs had been marked on the margin with a lead-pencil, and the pamphlet also contained, in addition to the article as it appeared in the *Journal*, a list, covering several pages, of the books and minor writings by the same author.

I think this subject worthy of bringing to the attention of the profession, because men who resort to this kind of advertising ought not to be eligible candidates for election to any office in our medical societies; and the members ought to be on their guard against allowing them to obtain positions of honor or trust which would indicate an approval by the profession of their methods of drumming up business. ⁂

New York, May 8, 1888.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 6 to 12, 1888.

McKee, James C., Lieutenant-Colonel and Surgeon. Granted leave of absence for one month. S. O. 107, A. G. O., May 9, 1888.

Par. 11, S. O. 104, A. G. O., May 5, is amended by Par. 4, S. O. 108, A. G. O., May 10, 1888.

Major and Surgeon Charles R. Greenleaf; Major and Surgeon Robert M. O'Reilly; and Captain and Assistant Surgeon John O. Skinner, are detailed as a board of medical officers to assemble at the U. S. Military Academy, West Point, N. Y., on June 1, 1888, to examine into the physical qualifications of the candidates for admission to the Academy, and, in connection with the Superintendent of the Academy and Commandant of Cadets, the members of the graduating class. S. O. 104, A. G. O., May 5, 1888.

Brown, Harvey E., Major and Surgeon. The leave of absence for seven days granted by Orders 68, Fort Barrancas, Fla., May 2, 1888, is extended twelve days. S. O. 90, Division of the Atlantic, May 8, 1888.

Loring, Leonard Y., Captain and Assistant Surgeon. Granted leave of absence for three months on Surgeon's certificate of disability. S. O. 105, A. G. O., May 7, 1888.

Brown, Paul R., Captain and Assistant Surgeon. Granted leave of absence for six months, on Surgeon's certificate of disability, with permission to leave the Division of the Atlantic. S. O. 107, A. G. O., May 9, 1888.

Benham, Robert B., Captain and Assistant Surgeon. To proceed from Fort Du Chesne to Fort Douglas, Utah, and report to commanding officer of that post, not later than 25th inst., to accompany battalion of Sixth Infantry to Fort Lewis, Col. Upon completion of this duty, will return to his station, Fort Du Chesne, Utah. S. O. 33, Department of the Platte, May 5, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 12, 1888.

Cabell, A. G., Passed Assistant Surgeon. Detached from U. S. S. Adams, proceed home, and await orders.

Simons, M. H., Surgeon. Detached from Naval Academy and to practice-ship Constellation.

HORWITZ, P. J., Medical Director. Leave of absence for six months, to leave the United States.

A Naval Medical Examining Board is now in session at the Naval Hospital, Philadelphia, for the examination of candidates for admission to the Medical Corps of the Navy. There are eleven vacancies in the list of assistant surgeons. Permits for examination can be obtained on application to the Secretary of the Navy.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT. — Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 12, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	10	3
Scarlet fever	170	42
Cerebro-spinal meningitis	3	3
Measles	150	14
Diphtheria	181	48
Small-pox	17	5
Yellow fever	0	0
Cholera	0	0

THE LATE DR. C. R. AGNEW.—At a meeting of the Alumni Association of the College of Physicians and Surgeons, held May 10, 1888, the following was passed:

Resolved, That the following memorandum be entered upon the minutes of the present meeting, and that a copy of the same be sent by the secretary to the family of the deceased and to the NEW YORK MEDICAL RECORD and the *New York Medical Journal:*

It becomes our sad duty to record the death, on Wednesday, April 18th, at his residence in this city, of our associate CORNELIUS REA AGNEW. He was the first President of this Association after it became incorporated, in 1873, and he served it faithfully in this capacity for a number of years. He held the same office, for the second time, at the time of his death. It was largely through his influence that the Association was changed from a formal and only feebly active society into an agency for the direct and vigorous promotion of the interests of the College in its work of medical education. From the very first, up to the time of his death, he never ceased to contribute time, earnest thought, and liberal offerings of money toward the attainment of this object. It is a pleasure for us now to think that he had the satisfaction, before he died, of witnessing the first-fruits of his own planting and unwearying cultivation. Without his energetic and untiring co-operation and wise counsel it is highly probable that a few spasmodic efforts at the beginning would have soon given place to the lifelessness that characterized the earlier period of the Association's existence.

To his sorrowing widow and children we would extend our sincere and heartfelt sympathy, begging them to accept from us the assurance that the memory of their distinguished husband and father will be warmly cherished by the numerous alumni of the College of Physicians and Surgeons in the City of New York.

NEW YORK, May 9, 1888.
A. H. BUCK,
G. G. WHEELOCK.

Extract from the minutes of the Annual Meeting of the Alumni Association of the College of Physicians and Surgeons. CHARLES HITCHCOCK, *Secretary*.

61 West Thirty-sixth Street, May 10th.

ISOLATION OF CONTAGIOUS DISEASES IN PUBLIC INSTITUTIONS.—Mr. James C. Bayles, the President of the Health Department of the City of New York, calls attention to this important subject by the following circular letter to the authorities of the different public institutions: "I am directed by the Health Board of this city to call your attention to the necessity for the provision of suitable facilities in your institution for the proper isolation of all cases of contagious disease that may come under your charge. It is, of course, evident to you that the inadvertent reception and the necessary temporary retention of cases of contagious disease, in contact with those dissimilarly affected, expose the latter class to a serious but preventable danger. The Commissioners of this Department, and also the Advisory Committee of the Academy of Medicine, consider that immediate steps should be taken to overcome this source of danger to the spread of contagious disease. It is deemed at present only necessary to call your attention to the requirement of this means of protection of the public, in order to secure the necessary action on your part to remedy the evil."

THE LIQUOR AMNII AND FŒTAL NOURISHMENT.—Dr. Opitz, of Chemnitz, in reply to Dr. Ott, who holds that the liquor amnii is concerned in the nutrition of the fœtus, brings forward a case of malformation which is preserved in the museum of the municipal hospital in Chemnitz, which seems to show that the nutrition of the fœtus must be independent of the liquor amnii. An apparently healthy and well-formed child was born, which respired normally and passed meconium and urine. It also sucked, but immediately brought up the milk in a frothy condition. A gum-elastic catheter was introduced into the œsophagus, but it could only be passed as far as the cricoid cartilage, consequently some obstruction of the œsophagus was diagnosed. The child lived six days. At the post-mortem examination it was found that the œsophagus ended abruptly in its middle third. The stomach was filled with meconium. A fine probe could be passed through the cardiac orifice into the trachea.—*The Lancet.*

HOW MUCH MAN EATS.—According to Richard A. Proctor, who writes in the *Cosmopolitan*, it has been calculated that, on the average, each man who attains the age of threescore and ten consumes during the course of his life twenty wagon-loads of food, solid and liquid. At four tons to the wagon, this would correspond to an average of about a hundred ounces of food per day, or, say, some one hundred and twenty ounces per day during adult life and about eighty ounces during infancy and youth. Most modern doctors agree in regarding one hundred and twenty ounces of food per day, corresponding to five or six half-pints of liquid food, and seven or eight pounds of solid food, as in excess of the real daily requirements of a healthy man or woman. Yet probably most of us take more than this, in one way or another, during the day. Dr. Lankester, from an extensive analysis of the dietary of soldiers, sailors, prisoners, and the better paid classes of artisans and professional men in London, found the average daily quantity of solid and liquid food to be one hundred and forty-three ounces. Doubtless many take much less; but unquestionably many take much more than this. When some one mentioned before Sydney Smith the twenty wagon-loads of food calculated for each man's allowance, he turned to Lord Durham, who like himself was corpulent (and not without sufficient reason), with the quaint remark, "I think *our* wagons, Durham, must be four-horsed ones."

CRACKED NIPPLES are treated with great success by Pinard, as follows: As soon as there are any appearances of cracks, or even tenderness of the nipples, a compress, folded in four and steeped in boracic-acid solution, three or four per cent., is applied. Oil silk is placed over the compress to prevent evaporation. Over this a layer of cotton wadding, and the whole secured by a bandage.—*Cor. Amer. Practitioner.*

DIGITALIS should not be given after its use ceases to increase the flow of urine. As to the dose, forty minims, four times daily, will generally secure the diuretic effect. —DR. STEWART, *Iowa. Med.*

The Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 33, No. 21 NEW YORK, MAY 26, 1888 Whole No. 916

Original Articles.

OBSERVATIONS ON THE NORMAL SACCULI OF THE ANAL CANAL, BOTH IN HEALTH AND IN DISEASE, AND ALSO ON THE PRETERNATURAL POUCHES OF THE SAME REGION, AS DESCRIBED BY DR. PHYSICK.

By WILLIAM BODENHAMER, A.M., M.D.,

NEW YORK.

THE anatomy, physiology, and pathology of the normal sacculi of the anal canal, as well as the preternatural pouches of the same locality, as described by Dr. Physick, together with other morbid pouches of the anus and rectum, are not as well understood as they should be, or might be; and they certainly are of sufficient importance, in the estimation of the writer, to justify him, or anyone else, in making an earnest endeavor to further elucidate the subject.

The writer will now proceed to the consideration of the anatomical characteristics of the normal sacculi of the anus, as described by anatomists.

It is positively declared by some writers that, until recently, the normal sacculi of the anus were scarcely known, being neither well understood nor well described by the old anatomists, who considered them to be mere accidental occurrences, being neither normal nor constant. The writer, however, will attempt to demonstrate that the normal structure of the anus denominated *valvulæ*, *lacunæ*, or *sacculi*, as they are severally called, is not a recent discovery, as some who ought to know better would have us believe, but was fully recognized, understood, and well described, as forming a portion of the natural apparatus, by some of the old anatomists, more than a century ago, and since then verified and exemplified by eminent anatomists of recent times, as will now be shown.

Morgagni and Glisson describe the lacunæ of the anus very correctly, but call them semilunar valves—*ani valvulæ semilunares.* Morgagni gives the following drawing of a vertical section of the parietes of the inferior portion of the rectum, showing the bases of the columns of Glisson, or, as they are also called, the columns of Morgagni, and the valves of the anus, as he denominates the lacunæ.[1]

The celebrated Ruysch has also described these semilunar lacunæ of the anus.[2]

Astruc, the author of the most complete treatise on the venereal disease of his time, says that, "in the margin of the anus itself, several short ducts, or rather *lacunæ*, appear, which convey a viscid humor." [3]

The celebrated anatomist Winslow also describes these lacunæ in the following concise manner. He says: "Near the extremity of the rectum, the rugæ, or folds, become in a manner longitudinal, and at last, toward the circumference of the inner margin of the anus, they form little bags, or semilunar lacunæ, the openings of which are turned upward toward the cavity of the intestine." [1]

The distinguished anatomist J. Hippol Cloquet gives a full and clear description of the lacunæ or sacculi of the anus. He says: "The inner surface of the rectum is usually smooth in its superior half, but in the inferior portion there are observed some parallel longitudinal wrinkles which are thicker near the anus, and are of variable length. These wrinkles, whose number varies from four to ten or twelve, and which are called the columns of the rectum, are formed by the mucous membrane and the layer of subjacent cellular tissue. Between the columns there are almost always to be found membranous semilunar folds, more or less numerous, oblique or transverse, of which the floating edge is directed from below upward on the interior of the intestine. These folds form a kind of lacunæ, of which the bottom is narrow and directed downward. There are observed, moreover, on the inside of the rectum, the orifices of mucous follicles, which are directed from above downward, and reddish villosities which belong to the mucous membrane. The follicles in question pour into the rectum a white and pretty thick mucus, so long as they are examined at some distance from the anus, but at the anus itself a hair is seen rising from the centre." [2]

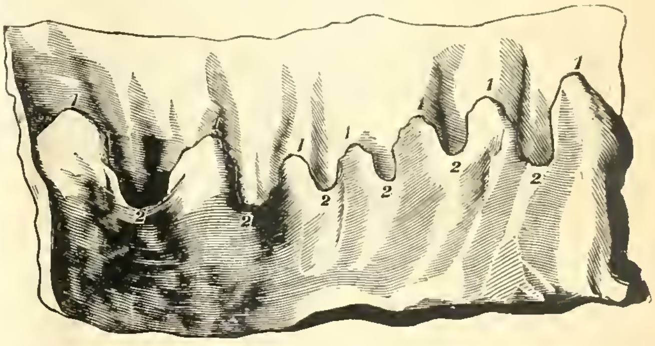

FIG. 1.—1, Ani columnæ; 2, interjectæ iisdem valvulæ semilunares.

M. Ribes describes the semilunar lacunæ, or sacculi of the anus, quite correctly. At one time, however, he denied their existence.[3]

Cruveilhier also describes the lacunæ or sacculi of the anus. He says: "The point at which the skin becomes continuous with the mucous membrane is deserving of notice; it is within the rectum, at the distance of some lines from the anus properly so called, and is marked by a waved line, which forms a series of arches or festoons, having their concavities directed upward. Sometimes there are small pouches in the situation of these arches, opening upward. From the angles at which the arches unite some mucous folds proceed, and small foreign bodies, detached from the fæces, are often detained in the cul-de-sac, and become the causes of fistulæ." [4]

The late eminent anatomist Professor Horner, of our own country, also describes the lacunæ or sacculi of the anus. He says: "The mucous coat of the rectum is thick, red, and fungous, and abounds in mucous lacunæ and glands. It is laid smoothly above, but below it is thrown into superficial longitudinal folds, called columns. At the lower end of the wrinkles, between the columns, are small pouches of from two to four lines in depth, the orifices of which point upward; they are occasionally the seat of disease, and produce, when they are enlarged, a painful itching. An original observation of Dr. Physick, on the nature of this affection, and the remedy for which consists in slitting them open, or removing them, induced me to look for the ordinary natural structure, which I have ascertained to be as now described."[1]

Dr. Horner gives the following drawing, which completely illustrates his description. Dr. Reynell Coates very minutely describes the normal sacculi of the anal canal; indeed, his whole article on the anus, in the "American Cyclopædia of Practical Medicine and Surgery," is the ablest production on the subject the writer has ever read. Dr. Coates says: "Immediately below the margin of the internal sphincter we find a series of membranous pockets, or sacculi, corresponding in number with the grooves between the columns of the rectum, one of which grooves is directed toward, and terminates in, each of the cul-de-sacs. On the outer side the sacculi are lined by the mucous membranes of the grooves, prolonged into the intervals of the hemispherical eminences already noticed, but which are not sufficiently distinct after death to be well represented in a drawing from nature. Internally, or on the side next the canal, the sacculi are completed by portions of loose membrane, which are processes from the reverted integuments lining the canal below. Each of these loose portions is attached, at either end, to the base of one of the columns of the rectum, and its free margin hangs in a curve between these points, thus forming a purse with the mouth presenting upward, and resembling in some degree one of those formed between the valves of the aorta and the parietes of that vessel. Unlike the sacculi said to be sometimes formed by the intersection of the transverse and longitudinal folds of the rectum, near the upper part of the anal canal, these pockets may be compressed, but cannot be obliterated by the distention of the anus. Their number, form, and position must necessarily vary with those of the columns and swellings, which give them attachment; and, like the columns, some of them are frequently rudimentary. The upper margins of these pockets, taken collectively, appear to form the festoon mentioned by Cruveilhier as the termination of the cuticle."[1]

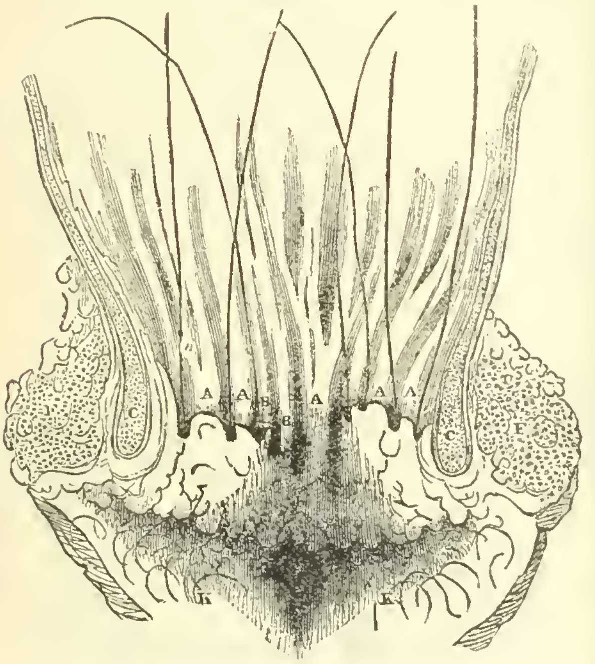

FIG. 1.—A Vertical Section of the Anterior Parietes of the Anus, with the whole Canal displayed so as to show the Relations of the Sacculi of the Middle Region, and their Relations to the Surrounding Parts, their Orifices being marked by Bristles. A, A, Columns of the rectum; B, B, rudiments of columns; C, internal sphincter; F, external sphincter; I, rudimentary or imperfect sacculi; K, K, radiated folds of the skin, terminating on the surface of the nates. *n*. A bristle in one of the sacs.

The writer could give additional authorities on the normal sacculi of the anus, but he deems those which have been presented quite ample to prove that the literature pertaining to this subject is neither scarce nor obscure, as some have declared, but abundant, and well understood by the intelligent portion of the profession. The writer himself has, for a number of years, paid considerable attention to this subject, having frequently examined the normal sacculi of the anus minutely, both in the living and in the dead subject. But these examinations only verified that which had already been demonstrated, namely, that the structure was normal and constant. He published some remarks on the subject in his treatise on "Anal Fissure," published in 1868, and in his work on the "Physical Exploration of the Rectum," published in 1870; and in both works he gave drawings of the probe-hook, and directions how to use it, to detect pouches or pockets of the rectum.

The writer will now consider the morbid condition of the normal sacculi of the anus, with a view to compare it with the preternatural pouches described by Dr. Physick himself, together with other morbid pouches of the rectum. It has always been a question with the writer whether the natural sacculi of the anus, morbidly affected, and the preternatural pouches of the same region described by Dr. Physick, were identical. The question is: Did Dr. Physick, in describing the preternatural pouches, mean the morbid condition of the natural pouches, or did he mean some other morbid production of these parts, independent of the normal sacculi? for it is certain that such pouches are sometimes found in the rectum, which are not occult fistulæ, and which have no connection whatever with, nor originate in, the normal sacculi, as can easily be demonstrated, and will be, further on.

The writer, however, is well aware that all surgical authorities, as far as he knows, claim that the preternatural pouches of Dr. Physick and the natural sacculi morbidly affected are one and the same malady. But the evidence upon which these distinguished authors attempt to establish this claim is, in the opinion of the writer, wanting, or at least is not made out clear, and rests more or less upon assumption; for they certainly do not arrive at such a conclusion from the description which Dr. Physick himself gives.

The writer will now present the pathogeny of the preternatural pouches or cavities of the anal canal, as described by the late and distinguished Dr. Physick, who alternately occupied the Chairs of Surgery and Anatomy in the University of Pennsylvania, and the question might here be asked, Who would be more likely to know than Dr. Physick himself of what he first discovered, described, studied, and successfully treated for a number of years? Was he mistaken?

Dr. Reynell Coates, the friend of Dr. Physick, says: "On the cause of the preternatural pouches or cavities of the anus, Dr. Physick entertains some views which can hardly be regarded as speculative. In his opinion they probably commence in the same manner with one of the forms of hemorrhoidal tumors—the constriction of the sphincters, which embarrasses the venous circulation of the part, aided by the pressure exerted in passing difficult stools, frequently giving rise to ecchymoses beneath the integuments. The effused blood produces no irritation of the cellular tissue in which it is placed, but forms for itself a simple inert receptacle. If the blood is neither absorbed nor discharged, but remains or becomes enlarged by successive ecchymoses, it constitutes (certain authorities to the contrary notwithstanding) one form of hemorrhoids. If, on the other hand, some accident, or the absorption of the integument gives exit to the blood after the cavity has become accustomed to its presence, the cellular tissue shows little disposition to reunite, no obvious marks of inflammation appear, and a preternatural cavity is established."

[1] Special Anatomy and Histology, eighth edition, vol. ii., p. 47. Imp. 8vo. Philadelphia, 1851.

[1] American Cyclopædia of Practical Medicine and Surgery, vol. ii., p. 83. Imp. 8vo. Philadelphia, 1841.

"In support of this explanation Dr. Physick states that in the early part of his practice he has in several instances operated on hemorrhoidal tumors of the same part, in which, after the removal of the coagula, the part presented the same aspect with the preternatural cavities, wanting only the orifice. He refers, also, to the existence of similar cavities, after the discharge of ecchymoses of the scalp, such as most surgeons must have seen, particularly in children, and which often prove tedious and difficult of cure. He has also observed the same accident in other parts of the body. In most cases the first appearance of the cavities was preceded by troublesome piles." [1]

Dr. Physick thus gives a full and graphic description of the origin, nature, cause, and characteristics of the affection which he denominates *preternatural pouches or cavities of the anal canal.* He plainly shows the origin of these pouches to be, first, the formation of hæmatomata, the result of a small quantity of extravasated blood into the loose submucous tissue of the part, from the rupture of a venule or venous capillary, consequent sometimes upon violent straining efforts to expel indurated fæces. A hæmatoma thus formed, and before opening and establishing an orifice, is the first stage of one form of hemorrhoids, and may be called an encysted submucous hemorrhoidal tumor, as the writer has fully explained in his treatise on the hemorrhoidal disease (p. 62). The contents of such bloody tumors may, under favorable circumstances, be in process of time absorbed, and the tumors entirely disappear. But this happy result does not always take place, for if the causes which first produced the tumors continue for a length of time, with the addition of prolonged irritation or inflammation of the parts, the very thin covering of the tumors sooner or later becomes absorbed, or is invaded by ulceration, and their contents escape into the anal canal, and the openings thus made, showing no disposition to heal or close, but remaining permanently open, are then, in reality, what Dr. Physick calls them, preternatural pouches or cavities. And, furthermore, these ecchymoses or hæmatomata, under the mucous membrane, are completely cut off from the circulation; they are not supplied with blood afterward from the same vessels which caused or produced the extravasation, and in this respect they differ very widely from the erectile and the varicose hemorrhoidal tumors, which are so abundantly supplied with blood-vessels. On opening one of these bloody tumors, and emptying it of the blood-clot, which is all that it contains, a little sac will be seen, which is lined with a smooth, soft, and delicate membrane which had, as it were, been thrown around the clot. The structure of such a sac resembles, in almost every particular, that of a degenerated normal sacculus, and which fact can be verified by any student. Furthermore, if anyone will examine the interior of the anal canal soon after forcible dilatation of the anal sphincters, he will find the mucous membrane studded with numerous small, round ecchymoses or hæmatomata, like good-sized bird-shot. These will under favorable circumstances soon spontaneously disappear, leaving no bad sequelæ; they are liable, however, from sufficient morbid causes of the mucous membrane, to degenerate and result in sacculi.

To illustrate this subject still further, in favor of the opinion of Dr. Physick, the writer will give the views of the distinguished French professor, M. Chaussier, on the origin of hemorrhoidal tumors, translating his words from the French as follows: "Hemorrhoidal tumors are due to a rupture of some of the capillary branches, situated in the cellular membrane, between the mucous and the muscular coat of the rectum. The blood being poured out of the ruptured vessels, raises up the mucous membrane, and forms on the spot a bluish or brownish tumor, just what we frequently see to result from the contusion or percussion of the skull, to arise almost instantly—a lump or bloody tumor, more or less voluminous; hence hemorrhoidal tumors, in the commencement, are only an ecchymosis, or an effusion of blood furnished by the rupture of some capillary branches, and which is accumulated, circumscribed, and retained under the membrane lining the inferior extremity of the rectum and margin of the anus. If the causes which have determined the extravasation of blood cease, and are not renewed, resolution occurs spontaneously and the tumor disappears. On the contrary, if constipation prevails, if the efforts of defecation are repeatedly made, if, at the same time, there is plethora, or a particular disposition to it, the tumor remains, it increases, and new ones form from it, either in the interior or on the exterior of the anus." [1]

It is evident from what has been presented that the preternatural pouches of Dr. Physick, whose description of them is very lucid and cannot be misunderstood, is an entirely different morbid production from that of the degenerated normal sacculi, and consequently they cannot be identical, as authors represent them to be; indeed, the opinion of Dr. Physick on this subject is not speculative but demonstrative, and does not in the least depend upon the diseased normal sacculi to sustain it.

The writer will now attempt to show how the normal sacculi become diseased or degenerated. It has been demonstrated that in health they have very small foramina and small cavities, and are in communication with follicles which supply them with mucus, which is poured out at the moment of defecation for the lubrication of the contiguous parts concerned; but, in consequence sometimes of continued excitation, irritation, or chronic inflammation of the mucous membrane in which they are located—they, of course, partake more or less of the same—they become relaxed, weakened, enlarged, and elongated, lose their contractile power, and permit foreign bodies readily to enter into their cavities; for unless their foramina and cavities are relaxed and enlarged by some efficient morbid cause, they are too small, when in health, to admit foreign bodies into them. As soon, however, as such bodies as small seeds, particles of fæces, fluids, or gases enter into any of these morbidly enlarged sacs, they produce great irritation, with a painful sense of distention of their delicate and highly sensitive parietes, attended often with a burning, smarting, itching, or tickling, which occurs soon after stooling, and lasts for an hour or two. It is positively stated by authors that the primary cause of disease in a sacculus is that a foreign body gets into it accidentally; but the writer maintains that this seldom if ever occurs, unless it is relaxed and enlarged by previous disease, so as to admit such a body into it. In the experience of the writer the degeneration of the anal sacculi is rare, he having met with only eleven cases in a practice of many years.

The writer will now name some of the distinguished authors who differed from Dr. Physick's pathogeny of the preternatural pouches, but, strange to say, give no good reasons for, nor any explanations of, the differences, but seem to ignore Dr. Physick's opinion on the subject altogether. If he was in error, it behoved them to point out the error in a plain and unmistakable manner, which they have not done; his opinion, therefore, whether right or wrong, stands unharmed by any sound argument or criticism brought against it.

[1] The American Cyclopædia of Practical Medicine and Surgery, vol. ii., p. 125. Imp. 8vo. Philadelphia, 1841.

[1] Dissertation sur les Hémorroïdes, p. 12. Soutenue par J. B. Lavedan. 8vo. Paris, 1814.

Dr. Gibson was the first author who differed from Dr. Physick, both in regard to the name and to the nature of the affection. According to the testimony of Dr. Reynell Coates, who, in reviewing the fourth edition of Dr. Gibson's "Institutes and Practice of Surgery," in 1835, says: "Among the other additions made since the first appearance of this work, we may name *Encysted Rectum*, a name applied with rather dubious propriety to the preternatural pouches detected by Dr. Physick, as to the true nature of which Dr. Gibson appears to differ from the discoverer."[1]

Dr. Gibson, in his treatise on surgery, after very accurately describing the normal sacculi of the anus, under the head "Encysted Rectum," says: "So far back as the year 1792, Dr. Physick met with a peculiar disease of the rectum, which had never been described or noticed by any writer. It consisted of one or more sacs of different dimensions, which, by bending a probe upon itself, introducing it into the rectum, and hooking it into the mouth of the sac, could be drawn down and made to appear on the outside of the anus. From that period he was accustomed, in his surgical lectures, to speak of this case, and others which he subsequently met with. From what has been said it will be readily inferred that this disease, to which the attention of Dr. Physick was originally drawn, must consist in an expansion or dilatation of the small natural sacs of the rectum described in the commencement of this section. Such we have every reason to believe to be the fact, though, strange as it may seem, no dissection has ever yet been made, so far as we are acquainted, calculated to demonstrate that the preternatural pouch is an actual enlargement of the natural one. From the circumstance, however, of small portions of fæces or of foreign bodies, such as seeds, having been found in the dilated sacs at the time of the operation, it is more than probable that these articles, by finding their way occasionally into the natural pockets, may, by irritating them, cause their expansion and elongation, and produce the disease in question."[2] It will be perceived that Dr. Gibson gives no reason why he applies the term *encysted rectum* to the morbid normal sacculi of the anus. The word *cyst*, in pathology, means a closed cavity, not an open one; and the word *encysted* means a bladder or bag contained within a cyst, as an encysted tumor. The writer agrees with Dr. R. Coates in saying that it is of dubious propriety to apply this term in the manner Dr. Gibson has done in this instance. This term, which originated with Dr. Gibson, has, by several authors, been accredited to Dr. Physick, as will be shown, but it is known that he never used that term to designate the disease which he called preternatural pouches.

Dr. Gibson gives no substantial reason whatever why he believes that the pouches of Dr. Physick and the normal sacculi of the anus are identical, and is candid enough to say that no dissection had ever been made to demonstrate the fact that the preternatural pouch of Dr. Physick is an actual enlargement of the natural one. Indeed, in the opinion of the writer, it is impossible by any process to reconcile the description of Dr. Physick, with the description of the morbid sacculi, so as to make it evident that they describe one and the same affection. Dr. Gibson attempts to explain the manner in which the normal sacculi become diseased, which is by foreign bodies finding their way occasionally into them, and irritating them, and causing their expansion and elongation. The writer has already shown that this expansion and elongation must first take place by disease of the mucous membrane, before the foreign bodies can find their way into the sacs, for unless they are previously diseased and relaxed such bodies will not find their way into them. He seems to think that because foreign bodies are found in the sacs when operated on, that such bodies got into the sacs first, and caused the disease in them, they being the primary cause. All morbid sacs or pouches of the anus or the rectum, especially such as have their orifices or mouths looking upward, as it were, are certain to be invaded by small foreign bodies coming down from above, and entering readily into the previously diseased and relaxed sacculi.

The late Professor Gross, when speaking of the diseased normal sacculi of the anus, says: "A singular affection of the anus, first described by Dr. Physick under the name of encysted rectum, is occasionally met with, though comparatively seldom. A more appropriate appellation for it would be, sacciform disease of the anus, as it consists simply in an altered condition of the sacs, pockets, or pouches naturally existing in this situation."[1]

Dr. Physick never described the disease he called preternatural pouches under any other name; the name encysted rectum has been shown to have originated with Dr. Gibson. Neither did Dr. Physick, in his description, have any reference whatever to the morbidly altered condition of the normal sacculi of the anus, as Dr. Gross implies.

Professor Henry H. Smith, in his "Operative Surgery," under the head "Encysted Rectum," when speaking of the preternatural pouches described by Dr. Physick, says: "These pouches were subsequently minutely examined by the late Dr. Horner, of the University of Pennsylvania, and their anatomical relations strictly defined, so that now they are usually regarded as a normal portion of the gut, which only demands interference when it becomes the subject of disease."[2]

The writer has already, in a previous part of this article, given the whole of Dr. Horner's description of the normal sacculi of the anus, including the very brief remarks he makes relative to Dr. Physick; these few remarks, with their immediate connection, will be repeated here as follows: "At the lower end of the wrinkles between the columns are small pouches, from two to four lines in depth, the orifices of which point upward. They are occasionally the seat of disease, and produce, when they are enlarged, a painful itching. An original observation of Dr. Physick, on the nature of this affection, and the remedy for which consists in slitting them open or removing them, induced me to look for the natural structure which I have ascertained to be as now described."[3] The writer has now fairly presented Dr. Horner's description of the normal structure or sacculi of the anal canal, and Dr. Physick's description of the preternatural pouches of the same region, and the two descriptions disagree entirely. Dr. Horner seems to have taken it for granted, as others have done, that Dr. Physick was in error, and that his pouches must be the morbidly enlarged sacculi. He does not, however, say, in that clear and unmistakable language, as implied by Dr. Smith, that he had by dissection demonstrated the fact that the affection Dr. Physick had described, and the enlarged normal sacculi, were one and the same disease. His language is not clear, and will not, in the opinion of the writer, bear this strict construction.

The writer will repeat that all the authors he has read on this subject differ from Dr. Physick, and seem to take it for granted that there are no preternatural pouches in the anal canal and rectum, except the normal sacculi morbidly relaxed; consequently, that Dr. Physick was wrong, and could not have meant any others but these. But pouches or pockets are sometimes found in the anal canal, and higher up, besides the normal morbid sacculi, and those described by Dr. Physick, for the writer himself has often seen such, and others also have often met with them. They are those which result from chronic dysentery, diarrhœa, or, at the close of exhausting or wasting diseases, causing follicular ulceration, especially in the rectum. The solitary follicles, in such cases, first become inflamed and disintegrated, and finally open on the surface of the canal; the openings, or orifices, at first quite small, and showing no disposition to heal, gradually enlarge, while the little cavities below them penetrate into the submucous tissue and thus become elongated, and finally result in sinuses, pouches, or pockets. The same result may take place from the destruction of small patches of the mucous membrane of the anal canal or rectum, by the same causes, as well as by tubercular or syphilitic ulceration, and, sooner or later, form small pits or pouches. All such, if not detected and treated, are liable, ultimately, to result in occult or other anal fistulæ. All anal and rectal pouches may be detected by a probe-hook, as Dr. Physick has advised. The following drawing represents the instrument used by the writer for this purpose. By such an instrument, carefully manipulated, these pouches may be detected without any injury to the parts. The probe-hook should be passed up into the rectum three or four inches, and then brought slowly back, with the point bearing successively on the different parts of the circumference of the canal; and should any preternatural pouch, morbidly enlarged sacculus, or occult fistula, exist, the reverted point of the probe will pass into its orifice and cavity, and render its existence and character at once sufficiently obvious.

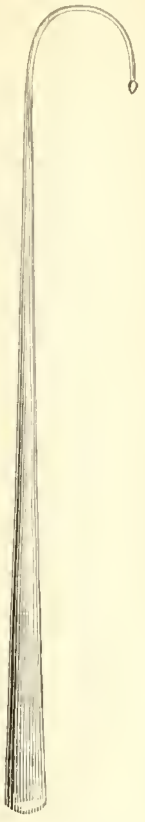

Fig. 3.

A hook for detecting occult anal and rectal fistulæ, and other pouches of the same locality, was used by Dionis and tabulated.[1] Heister also used a similar hook for the same purpose.[2]

The writer must now defer to another occasion the consideration of the subject of the causes, the symptoms, the diagnosis, the pathology, and the treatment of the different morbid pouches of the anus and the rectum.

27 East Forty-sixth Street, March 26, 1888.

Permanent Suppression of the Salivary Secretion.—A case of this rare description is reported by Dr. Rowlands, in *The Lancet*, as follows: The patient is a lady aged sixty, very thin and of a nervous temperament, and, although not vigorous, has always enjoyed fairly good health. She does not consider that the absence of saliva has made any difference to her general health. She gives the following history. About ten years ago, when in apparently good health, with the exception of a nervous shock caused by the news of the sudden death of a friend, she awoke one morning with an intense dryness of the mouth and throat, which prevented her from speaking or swallowing, and caused a sensation of choking. She found relief by constantly sipping cold water; but the distress was so great that for some nights she was unable to sleep. The discomfort gradually abated, but the tongue and mouth have remained perfectly dry ever since. The tongue has now the appearance of a piece of dry raw beef. There are no signs of papillæ on the anterior surface of the tongue, but the circumvallate are distinguishable. It is to be remarked that diminution, or even entire suppression, of the ordinary buccal secretions is sometimes observed in hysteria. But the affection is not a permanent one. In the cases reported above, it has not been conclusively shown that the secretion of saliva was altogether suppressed, for this may go on to a certain extent although the mouth appears quite dry.

SOME OF THE SIMPLE METHODS OF PERFORMING HYSTERO-TRACHELORRHAPHY.[1]

By O. E. HERRICK, M.D.,

LATE PRESIDENT OF THE GRAND RAPIDS ACADEMY OF MEDICINE, GRAND RAPIDS, MICH.

The rapidly advancing specialty known as gynecology seems to have stricken terror into the heads and hearts of certain members of the profession, many of whom are constantly entering protests against all mechanical and surgical interference in the treatment of diseases peculiar to women. Even surgeons who are known to be extremely radical upon the subject of general surgery are among the loudest in lamenting the frequency with which the gynecologist operates upon the female body. They do not seem to comprehend the fact that the same rule which governs ordinary surgery also applies to female surgery, and that conservatism is as likely to act as a check upon the one as upon the other. So long as "conscience makes cowards of us all" there is but little danger of humanity being injured by bold surgery, either general or special, at the hands of educated or reputable men. Each operator's regard for his own success and professional reputation will keep him as conservative as is compatible with his patient's welfare; there is no man so radical that he will knowingly perform a Cæsarean section if he can deliver his patient by ordinary methods; regard for his own welfare, if he care nothing for that of the patient, will keep him sufficiently conservative.

If the general surgeon and practising physician will be careful to keep *their* practice always within the bounds of conservatism, we can safely trust the operations of gynecological surgery in the hands of the eminent men who were present at the accouchement of the young but healthy specialty; and when they are no longer here to look after it, their recorded experience will be handed down as an heirloom to their sons, who will grasp with strong and sure hands the helm of the gynecological ship as it drops from the nerveless fingers of the great masters.

Almost all great things ever accomplished for either medicine or surgery, all great advances made, have been more or less abused and overdone during the stage of incubation: scientific facts are only reached after the explosion of many false theories. Enthusiastic discoverers almost invariably claim too much for their pet theory or hobby, be it operation, drug, instrument, or pathology, and what is good of discoveries is only appropriated after a careful weighing and sifting process by a critical and stern non-partisan jury of professional peers; only then do discoverers occupy their proper places and their discovery receive due credit.

Listerism has recently undergone the ordeal and taken its suitable place among the archives of medicine and surgery, not so high, to be sure, as its confident discoverer expected, but still much better than no place. Someone has said that it was the "best-blown medical bubble of modern times." I cannot agree with the sentiment which calls Listerism a bubble, for antiseptics surely hold an important place in both medicine and surgery, and as auxiliaries will always be useful, if they are not, as Dr. Lister expected they would be, indispensable. Operations upon the lacerated cervix has received a full share of attention since its discoverer first published his experience to the profession and detailed his method of operating. Since that time there have been thousands of lacerations operated upon by Dr. Emmet and other gynecologists; besides, these operations have been by no means confined entirely to specialists, for many surgeons in general practice have tried their hands at the new operations, and with all kinds of results. Emmet and others have claimed a great deal for the operation, and have charged upon the condition it is intended to remedy a multitude of sins, while some other gynecologists think too much is claimed for the operation, and too many abnormal conditions charged up to laceration of the cervix; just what the outcome will eventually be can now only be conjectured.

---

[1] Address of the retiring President, delivered at the Annual Meeting of the Grand Rapids Academy of Medicine, February 7, 1888.

There are, however, some undoubted benefits which have grown out of Emmet's teachings, and if there be no others added. the results have amply paid the investigation. Foremost and chief among these benefits has been the doing away of the old-time *ulceration*, which has been shown to be, in the majority of cases, a simple rolling out of the uterine mucous membrane. In all cases of complete laceration the lips spread apart as soon as the patient assumes the erect posture; this is caused by the weight of the uterus, which is always more or less increased after confinement, and consequently, when the woman rises the uterus presses downward, and its lacerated lips are drawn apart by the posterior lip catching upon the posterior vaginal wall. When the flaps formed by the laceration are once thus separated they are forced farther and farther apart by the anterior lip being forced forward in the axis of the vagina, thus producing constantly increasing traction upon the everted posterior lip. In such cases irritation is immediately established and involution of the whole organ arrested.

The angle of the laceration is the first point attacked, and erosion gradually extends over the entire everted surfaces. These facts being known, the importance of keeping the woman in bed and giving the lacerated parts time to heal before the upright position is assumed must be apparent to all. When this is not done, and the woman is allowed to get up before restoration of the parts has taken place, the uterus will continue to advance more and more toward the vaginal outlet, until in the majority of cases complete prolapse of the organ has taken place. As these conditions are progressing, the uterus will increase in size, and the mucous follicles upon the eroded surfaces will gradually enlarge by the constant irritation produced by rubbing against the posterior vaginal wall. These follicles after a time undergo cystic degeneration, and by bursting produce a profuse cervical leucorrhœa. After they are ruptured their cavities are gradually filled up by contraction, but while one set are undergoing this change others are being developed by the constant irritation, and in this way a constant leucorrhœa is kept up, with every now and then a bloody show, for when these little granular follicles are forming they are distended with blood, and the whole eroded surface bleeds upon the slightest touch. The patient is constantly tormented with all the ordinary symptoms of uterine trouble in general, such as backache, irritation of the bladder, pains down the thighs, ovarian neuralgia, etc., while added to these distressing symptoms there is in most cases marked nervous disturbances of almost every grade. As stated above, this condition of the cervix was, until Dr. Emmet demonstrated the difference, mistaken and treated for ulceration, and so generally has the error been practised that the idea has obtained among women that ulceration is the most frequent abnormal condition of their sex, while the profession all know, or should know, that it is one of the most rare conditions met with in the catalogue of woman's ills. Formerly these cases passed from one physician to another, only to undergo essentially the same treatment at the hands of each, which consisted of the frequent and repeated application of caustics in some form. This kind of treatment continued, in most cases, until either the patient became discouraged and gave up the hope of ever regaining her health, or until the profuse menstruation diminished, and the leucorrhœa ceased, from the cicatrization of the eroded surfaces by the constant application of caustics. They were then dismissed as cured, but, as a rule, they were very far from it, for the reason that with the impairment of their general health from the long continued uterine trouble the nervous system had received irreparable injury, which. together with the hypertrophy of the uterus that always remained, left them, in their anæmic condition, fit subjects for the development of epithelioma at the point of the old injury. Some robust women were enabled to so far regain their health, and the injury became repaired sufficiently to allow them to become pregnant and give birth to another child, perhaps a number of them, and in these parturient states and processes they obtained almost complete relief from their lacerations and its results, as the lacerations became in part or wholly healed during the process of involution.

These cases were of course the exceptions, but occurred with sufficient frequency to produce the belief among many of the older members of the profession that pregnancy was the panacea for ulceration of the os uteri, in common with almost all other non-puerperal uterine diseases.. Had the physicians confined their treatment to such wholesome advice their results would have been much better, and their experience would have robbed Emmet's operation of very much of its glory. That there are many conditions of uterine disease directly chargeable to laceration of the cervix, there can be no doubt at the present writing, especially among those who have taken the pains to investigate the subject.

Among the most frequent disturbances consequent upon laceration may be mentioned cellulitis, menorrhagia, dysmenorrhœa, endo-cervical metritis, metritis, hyperplasia of the cervix, sympathetic ovaritis, hypertrophy, and epithelioma. Besides these, Dr. Emmet, in a long list of tables collected from his cases and those of his colleagues, charges directly upon this condition almost every disease peculiar to women; and among the rest I notice that in his long essay upon menstrual changes, containing three long tables requiring a prodigious amount of study to make them intelligible to the ordinary mind, he concludes that "the general effect of the injury is to increase in after-life the length of the menstrual flow by an average of *nearly one day*." If his deductions are true, the necessity for an operation to remedy such condition will hardly be apparent. Another condition for which he recommends the operation is sterility, which he thinks is brought about by a greater or less degree of retroversion, existing as a result of the laceration extending into the posterior cul-de-sac and causing contraction of the parts or tissues located posteriorly.

Now I am entirely unprepared to deny, or even question, the truth of the pathology as quoted above. In truth, it seems reasonable; but any tyro knows that it is far from being a rule, and must have seen many pregnant women with both single and double lacerations. The liability, however, of the pregnant woman with a lacerated cervix to miscarry can be readily seen. It is beyond the scope of this paper to consider in detail all the conditions which the operation of Dr. Emmet is supposed to relieve, and I would not, if I could, mar in the least the lustre of his discovery, for if it is not all that has been claimed, there is enough good in it to be still a boon to suffering woman.

Perhaps it is strictly in accordance with facts that each condition mentioned above, and all others claimed by its discoverer, may in given cases be produced by a laceration of the cervix; but the point I wish to distinctly emphasize is, that by no means all cases of laceration of the cervix produce post-partum lesions; neither does every woman with a little rent in her cervix require it sewed up.

I am fully convinced that the claim that subinvolution of the uterus is associated with, and caused by, these lacerations is partly, but not universally, true; it does not necessarily follow that because there is a laceration, either single or double, the woman must needs be afflicted with uterine subinvolution. That there is greater liability, under such circumstances, I am ready to admit; but that the arrested involution can only be remedied through the medium of an operation to restore the cervix to its natural condition, I am unwilling to agree to, and for the reason that, through the administration of ergot, and local application of appropriate remedies, we are often able to bring about involution without in any way interfering with the lacerated cervix. In quite a proportion of cases there is entire immunity from any bad results following laceration of the cervix. When they do not heal up promptly and without any interference they will often remain in the lacerated condition for a lifetime without becoming everted in the least, and with neither erosion, hypertrophy, nor any of the other many local manifestations. In such cases it would be idle to interfere, or to charge upon the laceration all the nervous aches and pains which may occur in all parts of the body; where there is a button-hole laceration, or one through either the anterior or posterior lip, it would be meddlesome to attempt any operation, for the reason that the rent is almost sure to unite itself.

The other class of cases, and perhaps the larger class, are intolerant of almost any degree of cervical laceration, and are the cases liable to any and all of the morbid conditions attributed; these are the appropriate cases for operation.

Cicatricial tissue has been charged with causing much reflex irritability, and some teachers of gynecology have taught that morbid conditions were more often produced by the cicatricial tissue which covers the lacerated edges of the lips than from the eversion and consequent irritation of the edges, and have urged this theory in favor of frequent operations for closing them.

Emmet, Goodell, Pallen, Mundé, Skene, and many others, claim that all such tissue should be entirely removed, and especially the wedge-shaped cicatrix at the angle of the laceration. Emmet lays great stress upon the absolute and complete removal of all this tissue, as, he says, "it is often the cause of much reflex disturbance of the nervous system, and is frequently the cause of neuralgia in other parts of the body." He also says that when the parts are brought together without entirely removing the cicatricial tissue "there will be no improvement, even should they unite perfectly;" and, finally, "there will be a marked increase of the anæmia and the neuralgia, owing to the additional irritation to the nervous system, and nutrition becomes still further impaired."

While it is undoubtedly as well to remove the entire cicatrix while denuding the laceration prior to closing, I question the absolute necessity of the procedure, and should expect to get union of the edges even though there were a portion of the cicatricial plug left in the angle.

From the fact that there are in many cases of old lacerations extensive cicatrices without any marked nervous symptoms, and that there is always more or less cicatricial tissue at the line of union in lacerations that have healed spontaneously after childbirth without subsequent nervous disturbance, it would seem to be clearly proven that there are at least some cases with cicatricial tissue at the uterine neck without irritation of the nervous system and with permanent improvement. While Dr. Goodell has frequently advised its removal when practicable, he must have had the facts above stated in his mind when he said: "I have removed wedges of cicatricial tissue without restoring my patient to health. From my observations I am disposed to believe that the painful influence on the system of hard and gristly tissue left after some cervical tears has been overrated."

As Dr. Goodell's ideas upon this subject harmonize so well with the position taken in this paper, I continue to quote from his article in the *American Journal of Obstetrics* for January, 1882, in which he says: "Of the beneficial results of the operation of trachelorrhaphy, I must admit that I am not so sanguine as at first. The good rule may be laid down that when marked ectropion exists, associated with enlarged Nabothian glands, with leucorrhœa and menorrhagia, the issue of the operation will be a happy one. In such cases I have had capital results; when, however, I have operated on a tear without ectropion, or merely on account of cicatricial tissue in the angles of the fissure, I have met with bitter disappointments."

Operations for closing laceration of the cervix, as done by Emmet, Goodell, and many others, are by no means either simple or devoid of difficulties to the operator, or bloodless and free from subsequent danger to the patient, as many operators who, doing the operation for the first time, perhaps without skilled assistants, can testify. In fact, the operation, as described by Emmet in his work upon gynecology, is one of the most delicate and difficult known to female surgery, and whoever attempts it for the first time without professional assistance (which is often necessary in private practice, as many women strongly object to the presence of a second physician) will be quite liable to be in the condition of Dr. O. B. Will, of Dunlap, Ill., who said, in reporting his first case before the Peoria Medical Society: "My gynecological reputation was nearly wrecked. I wished most heartily I had never seen the patient, and she probably entertained like feelings toward me." That the operation as performed is needlessly tedious, and much too numerous in details, full of difficulties for the operator and unnecessarily painful and bloody to the patient, has been fully demonstrated in the last three years by myself and many other operators.

After the lacerated edges are well freshened it takes very little force to hold them sufficiently together to get union; this is often seen in cases where the edges have been touched with caustics, and especially where nitric acid has been used. They will sometimes unite without anything being used to hold the lips in contact, and if pledgets of lint or cotton are packed in closely around the cervix they will generally unite at least a portion of the distance, and sometimes complete union will take place.

Dr. Joseph H. Warren, of Boston, writing in the *Virginia Medical Monthly* for March, 1881, mentions this fact and says: "I have for nearly twenty-five years succeeded in uniting many a case by the application of the fuming nitric acid, after denuding the surfaces with the acid, coapting them in position, packing iodized cotton around the cervix, and inserting a stem pessary or a portion of a bougie."

I have had a similar though not so large an experience, and find that in many cases, especially where the tear is slight or limited to one side of the cervix, that the operation of Dr. Warren is quite sufficient for the purpose. I have also seen a number of cases, where the laceration had even existed for years, that united spontaneously; no doubt a slight inflammation was set up from some cause, and during the process the parts became adherent. One such case recently came to my notice while I was South.

Dr. W. H. Johnston, of Selma, Ala., asked me to see a case of laceration of the cervix which had existed for a number of years, with the view of having me operate upon it. We made an examination with a speculum, when to our great surprise the cervix was found to be intact and without a sign of laceration. He had not examined the case for over a year, but said there was a well-defined laceration nearly down to the juncture the last time he had examined the case. A number of other physicians had also examined the woman and diagnosed laceration of the cervix, and among the number was a specialist, who proposed an operation, but the patient had neglected having it done. The lady and her husband both declared that an operation had never been made. This was certainly a case where the laceration united without any operation. I was also called in consultation with Dr. J. M. Sligh, of this city, on a laceration of the cervix which he had often seen, and when we introduced the speculum we found that complete union had taken place.

Such cases are, of course, exceptional, but these two cases show they do sometimes occur, nevertheless; and while it would not be good practice to always wait for such chance results, it shows that the parts readily unite, and that it requires but little retentive power to secure such union.

In 1880 I reported for the Philadelphia *Medical and Surgical Reporter*, vol. xlii., No. 3, a "Modification of Emmet's Operation," which had for its object the doing away with sutures through the uterine mucous membrane, claiming they were unnecessary, as good union could be had without them, thus saving the patient much pain and the operator no little trouble, and making professional assistance not absolutely necessary, as the patient could be operated upon without being etherized. As the introduction of sutures is the most tedious step of the operation, it is also the most painful to the patient, and is the only part requiring special skill. The modification, in brief, is as follows: The lacerated edges of the cervix are denuded as usual, care being taken that they are properly coapted; then, instead of introducing sutures, a wide elastic rubber band, shaped like the cervix, and large enough to cover the whole os and neck, with the exception of a hole in the end for the secretions to pass through, is slipped over the os, while the lacerated edges are held together by a pair of tenaculum forceps, over which the band is first passed; the band being wide and covering the whole neck, it keeps up equal pressure upon the bloodvessels, thus preventing enough blood getting into the parts at any one time to produce inflammation or swelling, and, as a natural sequence, union takes place much sooner than it otherwise would. The introduction of sutures is often followed by inflammation, and when suppuration follows there is non-union, which is prevented by the use of the elastic band.

The advantages of this method are: 1. As about all the pain experienced during the operation is from the introduction of the sutures, if they are not introduced there is little pain, and hence an anæsthetic may be dispensed with. 2. If the patient is not etherized it is not necessary to have professional assistance, and one can operate upon patients that would not listen to such a proposition if strange physicians were to be present. 3. The parts are kept in just as close contact, and union takes place just as soon. 4. There is less danger of inflammation. 5. There are no stitches to remove. 6. In slight cases patients can be operated upon without their being obliged to keep their beds for a single day, or their knowing they are undergoing an operation. Since the publication of this method of operating in the *Medical and Surgical Reporter* the operation has been frequently performed, as modified, not only by myself but many other surgeons, some of whom have published their results, which have been uniformly successful.

Some have objected that it is somewhat difficult to throw the band around the cervix, and to always get a band that will fit every case. Considerable care is sometimes necessary in its accomplishment, and I have found that there are other ways of retaining the lacerated edges in apposition, and the following is the plan I most frequently adopt, as it does away with that objection, and holds the parts as firmly together as though sutures were introduced through the cervix. I take a piece of block tin about one-sixteenth of an inch thick, and long enough to reach around the cervix, then cut a strip wide enough to cover the cervix from the vaginal juncture to the end of the os; I then punch from three to six holes through each end of the strip, through which I pass silver wires, which are twisted with a pair of forceps until the cervix is grasped sufficiently tight to hold the lacerated edges firmly together. This proceeding is easily accomplished, and answers every purpose of sutures.

NOTES ON GLYCOCHOLIC AND FELLIC ACID.—A German observer, Schotten, says that glycocholic acid can be obtained in colorless crystals from fresh bile in the following simple manner: Add to the fresh bile a drop of hydrochloric acid, shake and filter. Now add to the filtrate ethyl ether and hydrochloric acid in the proportion of 5 parts of acid and 30 of ether to 100 parts of the bile. Shake well and allow to stand. Collect the crystals which will form, and wash them in water containing a small proportion of ether and hydrochloric acid. Dry the crystals in air. According to Schotten the second acid in human bile is neither choleic nor desoxycholic, but an acid of the formula $C_{23}H_{40}O_4$, to which the name of fellic acid is given. With Pettenkofer's reaction, it gives a red and not a violet color.

IMPACTED RENAL CALCULUS, WITH THE REPORT OF A CASE.[1]

BY GEORGE ROE LOCKWOOD, M.D.,

NEW YORK.

THE patient, Mr. President and gentlemen, whose history I bring before you this evening for discussion, is a gentleman forty-four years of age, of good physique and family history. His previous history was unimportant until sixteen years ago, at which time he began to suffer from attacks of renal colic on the *right* side, which recurred at about monthly intervals for a year, and then ceased. He does not remember having passed calculi at that time. He remained a well man until February, 1884, when he suffered from renal colic on the *left* side, convalescing, however, in two weeks. In July, 1884, he was again attacked by renal colic on the left side, and passed into a drowsy, uræmic condition, this uræmic state being relieved in four to five days by a free urinary flow. Just how much urine he had been passing during his uræmic stage is not known. This attack was followed by severe cystitis, which lasted till the following March, 1885, at which time a waterworn uric-acid calculus was passed; the cystitis then subsided until the following September, when it recurred, lasting till April, 1886.

Since this time he has passed gravel in moderate amount; but, except for an occasional aching pain in the left lumbar region, remained in good health until December 23, 1887.

At that time he was confined to the house, with dull pain in the left side, of its usual severity. His urine contained a trace of albumen.

December 27th.—Early on the morning, however, of December 27th he was seized with severe pain in the same location, sharper and more violent that ever before. This pain continued until the forenoon, when he suddenly passed into general convulsions lasting several minutes, the convulsions being followed by stupor of several hours' duration. During the stupor his pupils were contracted; his pulse of high tension.

He was given a hot-air bath, and his bowels freely moved.

For the first twelve hours he passed no urine at all; during the next twelve hours he passed 12 oz. of bloody urine, containing 46 gr. of urea.

December 28th. — On the second day patient was drowsy, pupils contracted, tongue dry. Temperature, 99°-100.2°. Pulse, 112, and of fairly high tension. He sweats freely in the hot-air bath—the sweat having a markedly ammoniacal odor.

Bowels were kept freely open, steaming continued, diuretics added.

During the twenty-four hours of this the second day he passed 18 oz. of clear urine, containing 142½ gr. of urea, albumen in moderate amount, with a small number of hyaline and granular casts.

December 29th.—On this the third day his condition was the same. During the twenty-four hours he passed 4¼ oz. of clear, sparkling urine, containing 35 gr. only of urea.

December 30th.—On the fourth day his condition was unchanged. He dozes most of the time, but is bright and intelligent when awake. There are no additional uræmic symptoms. Pupils still moderately contracted; pulse still of high tension. He sweats well in the vapor-bath, and the treatment is continued.

During this the fourth day he passed 4¼ oz. of urine, containing 39½ gr. of urea.

December 31st.—Condition practically unchanged.

During the fifth day he passed 4¾ oz. of clear urine, containing 48⅓ gr. of urea, and ninety per cent. of albumen, moist volume.

---

[1] Read before the Section on Practice, New York Academy of Medicine, April 17, 1888.

January 1st.—Condition unaltered. Careful physical examination has shown at no time the slightest evidence of abdominal tumor or of bladder distention.

During this the sixth day he passed $4\frac{1}{4}$ oz. of urine, containing 31 gr. of urea, and thirty per cent. of albumin.

January 2d.—Upon the seventh day, from 1 A.M. to 10 A.M., patient experienced several times a desire to urinate, but passed only $1\frac{3}{4}$ oz. during this time.

At 10 A.M. the desire to urinate returned, and, to his intense satisfaction, he passed, within an hour, $47\frac{3}{8}$ oz. of urine, the first few specimens being bloody, the color rapidly becoming clear and sparkling as the flow progressed. The urine was 1.013 spec. grav., and contained $363\frac{4}{5}$ gr. of urea. At the end of the hour he passed a fresh blood-clot, shaped like a plug, 4 ctm. in length.

During the next hour he passed 35 oz.; the next, 23 oz.; the amount passed hourly becoming less and less, until at midnight he was passing 8 oz. an hour.

During the day he passed $235\frac{3}{8}$ oz. of urine—1.012—containing 2,148 gr. of urea ($4\frac{1}{2}$ oz.), and thirty per cent. of albumin.

He had now emerged from his drowsy condition, but complained of great weakness. Paregoric was given to control the diuresis, and stimulants carefully administered.

January 3d.—Mind clear and bright. Pulse, 110, and of less tension. He passed, during the day, $88\frac{1}{2}$ oz. of urine—1.014—containing 1,062 gr. of urea, and forty per cent. of albumin.

Calculating, however, the amount he passed for the first twenty-four hours of his diuresis, we find he passed 299 oz., or $18\frac{3}{4}$ pints, and this amount contained 2,401 gr., or 5 oz., of urea.

January 4th.—During the day patient passed only $68\frac{1}{2}$ oz. of urine, containing $667\frac{1}{4}$ gr. of urea, and only a trace of albumin.

Toward evening he experienced a return of his old pain, which continued, in spite of opiates, until 4 A.M. of the following day. During this period of pain he passed only $1\frac{3}{4}$ oz. of urine.

January 5th.—At 4 A.M. patient experienced a desire to urinate, but passed only ʒ ij. of bloody urine, the first he had passed for four hours.

At 5 A.M., however, a free flow occurred, amounting to $188\frac{1}{4}$ oz. during the remainder of the day. With the occurrence of the flow his pain disappeared. The urine was of specific gravity 1.029, contained 1,220 gr. of urea, and was free from albumin.

January 6th.—Patient passed $139\frac{1}{2}$ oz., containing 1,004 gr. of urea.

January 8th.—Patient passed 110 oz., containing 1,141 gr. of urea and a faint trace of albumin.

From this time his urine became more natural in quantity and in amount of urea excreted, becoming normal in these respects in two weeks, but contained, and still does contain, albumin (one-half to four per cent.) with hyaline and granular casts. His recovery was rapid and satisfactory. About three weeks after his polyuria began, he passed two uric-acid calculi, one the size of a grain of rice, the other slightly larger. His *present* condition is good, and except for remembrances of the past he would consider himself a well man. During his illness either Dr. C. D. Scudder or myself remained in constant attendance, and great care was taken to secure accuracy in clinical data.

From his previous history, from the history of his recent illness, and from the passage of the calculi, I think there can be but little doubt but that he suffered from impacted calculi in the left ureter. Starting from this diagnosis as a basis, we are brought face to face with some interesting clinical problems. Let us consider, *firstly*, the period of anuria, and, *secondly*, the period of polyuria.

I. In the first place, then, why did he have anuria, or practically anuria, at all?

If the other kidney were competent there would have been no such history, as then it would have been able to assume the whole task of urinary secretion.

With such a history, however, as the patient presents, we must consider the other kidney to have been incompetent from either *functional* or *organic* causes.

(*a*) The *functional theory*—the theory that suppression of urine in one kidney may cause a sympathetic suppression in the other—seems a plausible enough one at first glance, but it is not supported either by the records of reported cases or by what we know of reflex inhibitions in general.

The only case I have been able to find where functional incompetence has operated to produce anuria is one reported by J. Rickman Godlee to the Royal Medico-chirurgical Society of London,[1] in which, after an attack of renal colic, anuria set in, and lasted for seven days. At the end of this time patient began to pass scanty, highly albuminous urine, which soon became more natural in quantity and in amount. Patient died, however, five days later from exhaustion. Autopsy revealed impacted calculus in right ureter—slight interstitial nephritis of left kidney.

You will notice that the inhibitory reflex suppression gave out some days before death, and this is in accord with what we know about inhibitory reflexes in general. We can understand inhibitory insufficiency resulting from such an acute irritation as the passage of a renal calculus, but it is difficult to understand how such an inhibition can be operative over a considerable period of time, especially after the acute irritation of the opposite kidney has subsided.

(*b*) Falling back, then, upon the theory of *organic* incompetence, we find more abundant clinical testimony.

Julia Fontanelle[2] and Jonathan Hutchinson[3] have reported a case each in which fatal anuria resulted from calculus impacted in one ureter, the other kidney being congenitally absent.

Dittell[4] reports a horseshoe kidney with double pelvis, each being separately but coincidentally blocked by calculi.

Murbeck[5] reports a fatal case of anuria resulting from impaction of calculus in one ureter, the opposite kidney being previously destroyed by hydatids.

Rayer[6] reports a case of calculous obstruction on one side with hydronephrosis on the other.

By far the most common cause, however, of the organic destruction is previous calculous disease—the impaction of a calculus upon a previous occasion having been followed by atrophy of that kidney.

Roberts[7] reports four such cases. Parker,[8] Nunnely,[9] Rayer,[10] Alberti,[11] Fuller,[12] Paget,[13] Bagshawe,[14] Bischoff,[15] Tenneson,[16] and Dickinson[17] report similar cases.

Reviewing, then, our case at this stage, it seems most likely that sixteen years ago. when he complained of pain in the *right* side, his right ureter became occluded by a calculus; that atrophy of that kidney (not hydronephrosis, as we shall see later) has resulted, and that he has gone on since then with but one working kidney until *its* functions were thus suddenly arrested by occlusion of its duct.

A word in reference to the period of the anuria in these cases. In all the cases reported three noteworthy facts impress us:

1st. The long duration of the anuria.

2d. The immunity from uræmic symptoms.

3d. The possibility of recovery even after a long-continued anuria.

The first two points are well illustrated in Bischoff's case,[1] in which anuria of twenty-three days' duration is recorded, and not until the twenty-first day did uræmic symptoms intervene, and even then they were of mild character.

The possibility of recovery after a long-continued anuria is illustrated by the case I have presented to you. Such a happy conclusion, however, is rare. I have been able to find only twelve cases reported.

Russell[2] narrates a case of recovery after twenty-one days' anuria; Ostrander,[3] recovery after eight days; Reliquet,[4] recovery after fourteen days; Salgado,[5] thirteen days; Roberts,[6] one case, nine days; another case, ten days; Bartels,[7] five days; Hutchinson,[8] six days; Laing,[9] six days; Picard,[10] nine days; Tournadre,[11] eight days; and Peshek,[12] nine days.

It would seem that here we have a striking point in differential diagnosis between the obstructive anuria of impacted calculus and the non-obstructed anuria of inflammatory origin. In the former, a longer period of anuria, and without marked toxic symptoms, from which the patient may recover; in the latter, an anuria with eruptions of severe uræmic symptoms, more rapidly terminating in a fatal issue.

II. When we come to consider the period of polyuria we are led to ask ourselves what the cause was of the sudden and abundant flow of urine. To this there can be but two answers. Either it came from the emptying of a hydronephrotic distention of the urinary tract above the impacted calculus, *or*, it was due to a true *diuresis* without the formation of any hydronephrosis at all.

I am strongly inclined to believe that the latter is the true explanation in our patient.

I will start with the somewhat dogmatic statement that *hydronephrosis never originates* from a sudden and complete occlusion of the ureter. I make this assertion, well aware that it is at variance with many good authorities. For example:

Ralfe,[13] in a recent work on the kidneys, says: "It is when the occlusion is more or less permanent and *complete*, and *has come on suddenly*, that the hydronephrotic distention of the kidney acquires a considerable size."[14]

Henry Morris,[15] in a paper on hydronephrosis, read before the London Medico-chirurgical Society, says that when hydronephrosis exists there has been *sudden* and *complete* obstruction to the urine secreted by a kidney in its full function; that instances occur in cases of impacted calculus. "Up to the time of obstruction," he writes, "the kidney has been rapidly secreting, *it still goes on doing so*,[16] and the urine, finding no exit, dilates the pelvis and upper end of the ureter."

Let us examine this statement more carefully.

In the first place, we know that the extent and rapidity of urinary secretion are directly affected by the arterial pressure within the Malpighian tuft. The greater the excess of arterial pressure within the tuft, over the pressure in the urinary tubule without the tuft, the greater the amount of urine secreted. If, then, we can offer an opposing force which shall so neutralize this arterial tension that the pressure without the tuft equals the pressure within the tuft, there can be no secretion.

This Hermann[1] did by inserting a mercury manometer within the ureter, imitating exactly the conditions produced by impacted calculus. A pressure of 10 mm. of mercury, he found, caused a sensible diminution in the flow of urine, which diminution became more and more marked as the mercury-pressure became raised, until with a column of 60 mm. Hg. (2.4 inches) the two pressures were in equilibrium, and urinary secretion was completely suppressed.

Alexander James,[2] in a paper on the "Mechanism of the Bladder and Ureter," makes the statement that in four hours after complete obstruction to the ureter, the pressure becomes sufficient to arrest the secreting function.

Roberts[3] writes that ʒ ij. to ʒ iij. of pent-up urine are enough to check secretion, and he substantiates his statement by autopsies.

According to Edes,[4] when the ureter of a rabbit is ligated, atrophy of the kidney, with but little dilatation, is observed; the pressure of the urine puts a stop to further secretion.

In the second place, the ureter and pelvis of the kidney are not easily to be distended.

Bennet May,[5] injecting water into the cut end of a human ureter, could only inject one-half ounce. When this amount had entered, resistance to further injection became extreme. On applying more force, the liquid flowed out from the renal vein.

James, in the paper referred to, has proved that the ureter can stand a strain of 5 feet Hg.—the greatest possible pressure exerted by pent-up urine is 2.4 inches. How, then, can dilatation occur?

Thirdly, these statements are substantiated by autopsies. From ʒ ij. to ℥ j. is usually all the urine found pent up in recent cases. In old cases the kidneys are found atrophied and not hydronephrotic.

An occlusion of the ureter, then, causing a back pressure of 2.4 inches Hg., is regularly followed by suppression of urine and atrophy of the kidney. It is only when the back-pressure of the pent-up urine is less than this, and continuous, that hydronephrosis occurs.

We come, then, by exclusion, to find the explanation of the flow in a true diuresis, and we are led to place confidence in the fact that such a diuresis is possible, and probable, for two reasons.

1. That after such a prolonged anuria, with so scanty an urea excretion, there must be an abnormal abundance of urea and urea-like compounds in the blood, and these we know act as direct diuretics.

This was proved by Moutard-Martin and Pichet,[6] in experiments on curarized dogs. The rate of urinary secretion having been determined, urea was injected hypodermically. The amount of urinary secretion was first greatly increased—in one case trebled—and this more abundant urine showed, after some minutes, an excess of urea percentage; the first effect being a diuresis, the second effect being the elimination of the offending irritant itself.

The second reason is one not capable of direct proof, and one which I have not seen mentioned in the literature of the subject. It is this: We notice, for example, the increased vascularity of a limb after the removal of an Esmarch bandage from vaso-motor relaxation. Why should not such a localized congestion take place in the kidney when the pressure of the pent-up urine is suddenly removed? If this *does* follow, we have the most favorable condition for diuresis, viz., a relaxation of the renal artery without compensating relaxation elsewhere.

It seems to me that this vascular condition, with the direct stimulation of the renal epithelium by the increased urea in the blood, would favor both elements of urinary secretion—filtration and secretion proper—and account not only for the amount of urine passed immediately after the dislodgement of the calculus, but for the continuance of diuresis several weeks afterward. This latter the hydronephrotic theory will not account for.

What effect this vascular condition of the kidney had upon the elimination of albumin, I cannot say; but it seems probable that the excessive amount of albumin passed during the first diuresis might well enough be thus accounted for.

In conclusion, I desire to extend my thanks to Dr. Gerardus H. Wynkoop, for the privilege he has given me of bringing the case before you for discussion; to his partner, Dr. Charles D. Scudder, for his invaluable assistance in supplying clinical data, and to Dr. Johnson, of Waverly, N. Y., for the record of previous history.

SOME INTERESTING CLINICAL PHENOMENA OBSERVED IN A CASE OF CIRRHOSIS OF THE LIVER.[1]

By GEORGE R. ELLIOTT, M.D.,
NEW YORK.

THE subject of this communication is a male, thirty-eight years of age, Irish by birth, married, salesman by occupation. Family history is good.

There is a clear history of acquired syphilis, and for years he has drunk freely of the strong alcoholic liquors. Prior to 1876 he was very rugged. Since 1876 he has lost his voice at times, so that he could not speak above a whisper, and these attacks of aphonia would last from a few days to weeks.

I saw him for the first time in November last. He then gave a history of having been jaundiced four months, and sought treatment for his throat, having been unable to speak aloud for months, and having undergone treatment for same by a number of physicians without relief.

Aside from the throat symptoms he did not complain; he could eat and sleep well, and was free from pain and digestive disturbances.

He sought to regain his voice in order to resume his place as a salesman, which he had been compelled to give up from his inability to talk aloud.

Laryngoscopic examination of the throat failed to show sufficient local cause for his profound aphonia.

His slight icteric hue incited me to make a careful examination, which revealed the following:

Area of liver-dulness considerably diminished, while that of the spleen was markedly increased.

There was slight ascites and some œdema about the ankles; the veins about the lower part of the abdomen were enlarged and tortuous. Urine normal. Heart and lungs normal.

The patient was informed that his major difficulty was cirrhosis of the liver, and his loss of voice purely an accompanying symptom.

Treatment was advised to that end. Antisyphilitic treatment was tried, but availed nothing. Under the use of iodide of potassium his condition became decidedly worse.

The abdominal enlargement became enormous, and anasarca developed to a considerable degree, localized in the lower part of the trunk and lower extremities.

There was slight hydrothorax in the right pleural cavity; dyspnœa moderate. Various diuretics were used, without materially increasing the quantity of urine, which did not vary far from two and a half pints daily. It was normal as regards specific gravity, absence of albumin, and casts. Cathartics, causing copious watery stools, were freely used.

At this time Dr. G. L. Peabody saw him in consultation with me. Dr. Peabody confirmed the diagnosis, and agreed that little could be done other than a continuance of the rigorous symptomatic treatment inaugurated. Dr. Peabody advised trying strophanthus, and it was agreed on, as a preliminary step, to use nitro-glycerine. The arterial tension was high, this largely the result of digitalis, but the increased arterial tension seemed rather to decrease than increase the diuresis. Nitro-glycerine tablets, āā gr. $\frac{1}{100}$, were administered every two hours. Almost immediately there followed a decided increase in the quantity of urine voided, the quantity increasing from two to six pints in the twenty-four hours. After twenty-four hours the nitro-glycerine was replaced by strophanthus, which maintained the large quantity of urine voided, and this with arterial tension moderately low.

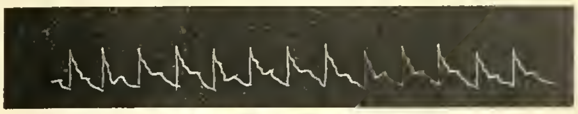

FIG. 1.—Urine, two and one-half pints in twenty-four hours.

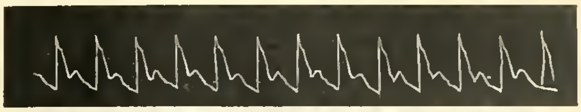

FIG. 2.—After taking nitro-glycerine, gr. $^1/_{100}$, every two hours, for twenty-four hours; arterial tension diminished; urine, six pints in twenty-four hours.

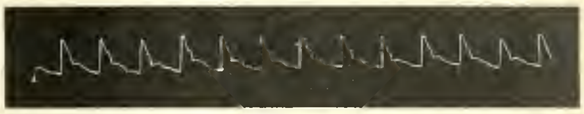

FIG. 3.—After taking digitalin, gr. $^1/_{100}$, every two hours, for twenty-four hours; arterial tension increased; urine, two pints and twelve ounces in twenty-four hours.

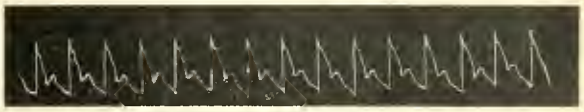

FIG. 4.—After taking tincture of strophanthus, gtt. x., every two hours, for forty-eight hours; arterial tension again diminished; urine, six and one-half pints in twenty-four hours.

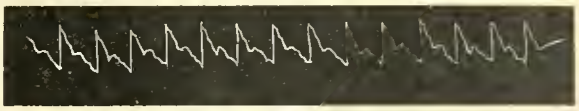

FIG. 5.—After tincture of digitalis, gtt. v., every four hours, for twenty-four hours; urine, three pints in twenty-four hours.

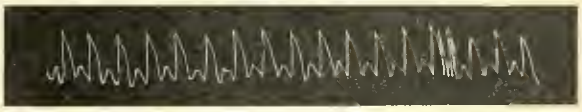

FIG. 6.—Fully dicrotic pulse; has taken neither digitalis nor strophanthus for twenty-four hours; urine, three and one-half pints in twenty-four hours.

By substituting digitalis for the strophanthus the arterial tension would apparently increase decidedly, and the quantity of urine would drop from six pints to three in the twenty-four hours.

By continuing the baths, diuretics, and purgatives the dropsical accumulation entirely disappeared, excepting a slight œdema about the ankles, and the patient became stronger.

Emaciation, however, progressed, and was especially noticeable about the upper extremities, neck, and face. He remained free from dropsical accumulations for some six weeks, during which time his strength improved so that he was able to go out and walk short distances.

With the disappearance of the fluid, it is interesting to note the complete disappearance of the aphonia.

While thus apparently improving, he was suddenly seized with a violent pain, localized in the right axillary line, accompanied by a febrile movement and hacking cough.

---

[1] Read before the New York Academy of Medicine, Section on Practice, April 17, 1888.

Examination revealed pleurisy with effusion.

The pleuritic friction-sound was well marked. Under treatment the pleuritic symptoms subsided.

Now the dropsical condition again gradually returned, and his strength would not admit of the extreme measures being used that had proved so valuable a few days before.

The ascites became now again marked; anasarca manifested itself in the upper as well as in the lower extremities. The right pleural cavity became nearly filled with fluid, and the dyspnœa extreme. The latter symptoms were temporarily relieved by the withdrawal of one gallon of bloody serum from the cavity.

He finally sank into a condition of semi-stupor, and died comatose on the afternoon of March 25, 1888.

The only cardiac symptom was a slight systolic murmur heard at the base of the heart and transmitted a short distance up the great vessels of the neck.

Autopsy.—Autopsy made thirty-two hours after death. Body considerably emaciated, but showing well the condition of general anasarca.

Pericardium contains about two ounces of bloody serum; no evidence of pericarditis. The heart is not materially changed from the normal, either in the thickness of its walls or the size of its cavities.

The aortic valve shows slight thickening at the attached border of its cusps. The other valves of the heart are normal.

The left pleural cavity contains about one ounce of serous fluid. The right pleural cavity contains about three quarts of bloody serum, and its thoracic and diaphragmatic surfaces are covered with lymph.

The left lung is normal.

The right lung is compressed against the spinal column to such an extent that it is not larger than would be represented by a ball three inches in diameter. Its substance presents the condition of carnification.

The abdominal cavity contains about two quarts of serous fluid.

The peritoneum is normal.

The intestinal mucous membrane is congested. Stomach shows evidence of chronic gastritis, and the veins about the pyloric end are very large and tortuous; common bile-duct pervious. The liver is markedly diminished in size, weighing two pounds and eleven ounces. Surface nodular, presenting the well-known "hob-nailed" appearance, and throughout its substance the lesion of cirrhosis is exceedingly well marked.

The spleen is greatly increased in size, weighing three pounds. It appears to be only hyperæmic, showing but very little hyperplasia of the connective tissue; there is also evidence of *perisplenitis.*

The right kidney is enlarged, capsule non-adherent, surface smooth, markings fairly well marked. Left kidney is in a similar condition.

Larynx *normal.*

Microscopical examination of the kidneys shows nothing abnormal, beyond excessive hyperæmia.

Certain clinical phenomena observed in the progress of this case would seem to merit some consideration, and I wish briefly to emphasize the following:

1. *The marked scarcity of gastric symptoms.*—The stomach remained able to digest food up to ten days prior to death, and hæmatemesis occurred but once, at a late stage of the disease. His complaints were few, and he was a decidedly close observer.

2. *The healthy action of the kidneys.*—The urine at no time contained *albumin* or *casts*, or other signs indicative of nephritic complication.

Just prior to death the urine became scanty, and the inability to obtain any of it is to be regretted.

3. *The complete disappearance of the dropsy*, after it had steadily progressed, in spite of treatment up to a point almost incompatible with life, and remaining absent for a period of weeks, and this directly traceable to the action of remedies which apparently decreased the arterial tension.

A steady increase of the dropsy had taken place, in spite of antisyphilitic treatment—in spite of almost heroic medication directed to the end of inducing free catharsis, diuresis, and diaphoresis. As long as digitalis was used, and the arterial tension high through its effect upon the arterioles, the quantity of urine voided was comparatively small; but just as soon as the action of digitalis upon the blood-vessels was rendered *nil* by the aid of nitro-glycerine, and the heart's action sustained by strophanthus, the diuresis was greatly increased.

It is already an established physiological fact that strophanthus exerts a more powerful action upon the heart, and a less powerful action upon the blood-vessels than digitalis.

The case under consideration illustrates well the significance of this action to therapeutics.

Digitalis increased arterial tension, but at the same time diminished, rather than increased, the diuresis.

Strophanthus also increased arterial tension, but caused a very decided increased diuresis.

An explanation would seem to rest upon the fact that in the former case the high arterial tension was due to the action of the drug upon the blood-vessels, and the arterioles of the kidneys, affected in common with other vessels, were practically in a condition of spasm, thus greatly interfering with the *filtration function* of the kidney.

That such was the case is rendered probable by the free diuresis which immediately followed the use of nitro-glycerine, and this is further sustained by sphygmographic tracings of the pulse, which, by the free excursions of the needle, show diminished tonicity of the walls of the blood-vessels.

This free diuresis was maintained by the use of strophanthus.

The substitution of digitalis was followed almost immediately by the same increased arterial tension, the same apparent spasm of the arterioles, the same diminished diuresis—all of which gave way at once upon the re-employment of strophanthus.

This observation at least would seem to show certain advantages of strophanthus over digitalis, in certain conditions where some of the good effects of digitalis would seem to be antagonized by the action it so strongly produces upon the blood-vessels.

4. Not the least interesting fact connected with the progress of this case is the complete restoration of voice following the disappearance of the dropsy, and this, too, without local treatment. Notwithstanding the fact that this patient had been subjected to prolonged courses of treatment by several eminent throat-specialists of this city, on the basis of a local malady, the original supposition that the aphonia was not due to a local lesion *per se*, but purely secondary, and probably dependent upon an œdematous condition of the mucous membrane of the larynx, would seem to be borne out by the complete restoration of the voice with the disappearance of the dropsy and the healthy condition of the larynx revealed at the post-mortem.

48 East Twenty-sixth Street.

Typhoid Fever and Pregnancy.—1. Typhoid fever is rare in pregnant women. 2. It determines abortion in about one-half of the cases; the more surely, the less advanced is the pregnancy. 3. The lightest forms may produce abortion. 4. This complication arises usually in the course of the third week, and sometimes at the beginning of convalescence; it causes no recrudescence nor return of fever. 5. Puerperal accidents are the exception.

A New Symptom Characteristic of Cancer Uteri has been brought out by Petit, Troisier, and Raymond. Each of these gentlemen found the existence of an enlarged lymphatic gland above the left clavicle in cases of cancer of the cervix uteri.—*Cor. Amer. Practitioner.*

VERSION BEFORE LABOR IN MALPOSITIONS OF THE FŒTUS.

By EDWARD A. AYERS, M.D.,

INSTRUCTOR IN OBSTETRICS IN THE NEW YORK POLYCLINIC, N. Y.

Fœtal mortality, maternal lacerations of the cervix and perineum, vesico-vaginal and recto-vaginal fistulæ, uterine ruptures, and pelvic inflammations are so much less frequent, proportionally, in occipito-anterior presentations in labor than in any others, that any procedure that will convert the latter into occipito-anterior presentations without adding new dangers should receive hearty approbation. In occipito-posterior presentations a severe laceration of the perineum, and perhaps the sphincter ani, is the rule where craniotomy is not performed, unless episiotomy be judiciously employed. In addition, the dangers of prolonged and laborious labor fall to the mother's lot.

In breech presentations the necessity of haste in the completion of the second stage imposes great risk to the cervix and perineum. In transverse presentations the dangers to the mother are very great. Spontaneous version or evolution, artificial version or evisceration, are means of relief that are usually obtained only after prolonged exhaustion and pressure, with local blood stasis, have supervened. Generally speaking, the only cases in which occipital presentations may be undesirable are such as can be accomplished by podalic version in preference to cephalic perforation.

We have, then, an argument of almost universal inclusion in favor of the conversion of all presentations to that of occipito-anterior, depending upon the comparative dangers involved in bringing about such changes. Version, when the cervix has dilated and the membranes ruptured, is a difficult and dangerous operation, on account of the active contractions of the uterus, the retraction that has taken place, with loss of space in the uterus, and the risk of sepsis. Wigand, in 1807, argued clearly, forcibly, and effectually in favor of version before labor, and with such complete monographs in our possession to-day as those of Pinard on "Abdominal Palpation," and Mundé on "Obstetrical Palpation," it seems strange that this procedure is not more generally employed.

In version before dilatation of the cervix the conditions that will increase the difficulties are: Scarcity of amniotic fluid, largeness of the child, thickness of the abdominal wall, and firmness or irritability of the uterus. But it is in reverse conditions, *i.e.*, abundance of amniotic fluid, diminutiveness of the fœtus, and laxity of the uterine and abdominal walls, that breech and transverse presentations usually occur. In fact they are frequently the result of such conditions. Therefore, as a rule, the conditions are favorable for turning before labor in those presentations that require correction.

If we hesitate in completing version before labor where the accomplishment is difficult—a situation most apt to exist in breech presentations—we must consider which will be more conservative to both mother and child, the difficult immediate version or the final delivery in the malposition. Immediate version should not always gain our approval. The practical application of early version involves a change of custom with both patient and physician, probably a bigger stumbling-block than the operation itself. Patients must be trained to recognize the early engagement of the accoucheur, and abdominal examinations before labor as the proper custom. Inasmuch as vaginal examinations are usually unnecessary in making a diagnosis of fœtal position in utero, patients will more readily submit to investigation. I have found the following general rules most useful and necessary in making the diagnosis of fœtal position by abdominal palpation.

With the patient lying upon her back, the thighs well flexed, and bladder empty, we should first seek the fœtal head. If it is at the "brim," by passing the fingers of both hands downward and backward, starting two inches above the symphysis, with a space of three inches between the index-fingers, it will be felt as a hard, incompressible body of a diameter corresponding to that of the fœtal head. In most cases after the eighth month the portion of the head lowest in the pelvis will be beyond the fingers' reach. If the head is not at the brim, search for it in other parts until found. It is much the easiest recognized of any of the fœtal parts. If it is at the fundus or at either side it will, in cases of difficulty due to excess of amniotic fluid, be found more readily by *ballottement*. The breech very rarely affords this sign. The hard character of the head, as compared with the fleshy shoulder, back, or breech, will also be recognized in this class of cases, and also when the abdominal walls are thick.

If the walls are thick and the amniotic fluid scarce, cephalic outlines or density can almost invariably be recognized. Having found the head, the back should next be found, not the breech. Following the head there will be found either a large cylindrical body, the back; or small irregular bodies, the extremities. Frequently both can be felt. In such cases the fœtus lies upon one side. Knowing which way the back is turned, we can tell the position of the head or breech at the pelvic inlet, unless it be a transverse presentation. If the back lies forward in cephalic presentations, the occiput will be anterior and right or left, as the back lies to the right or left; or if it is a face presentation, a fact next to be determined, the diagnosis will not be difficult. The position of the back will in the same way give us the position of the fœtal sacrum in breech presentations. To determine the degree of extension or flexion of the occiput, a fact necessary for diagnosticating by abdominal palpation, face, brow, or occipital presentations, ascertain the angle of junction of the head with the shoulders and back. If the angle is very obtuse and unrecognizable, it indicates extension of the occiput; if acute, extension of the chin.

Palpation through the anterior wall of the cervix with the index-finger will serve to confirm judgment as to the *presentation*, but not as to the *position* of the presenting part. The custom in serious cases of introducing the entire hand to diagnosticate "position" cannot become obsolete too soon. The differentiation between the breech and head at the inlet is gained in this way: In head presentations the fingers cannot reach the most inferior portion, as the head rests too low in the pelvis, except in hydrocephalus or pelvic distortion; but in breech presentations the fingers can generally pass below the fœtus and meet with only the maternal tissues between them.

Before attempting version, localization of the placenta would be desirable, but the "bruit" is a diagnostic myth, and recognition of its additional thickness to the uterine wall too difficult. We can only be careful in manipulating the fundus. When to perform version before labor will depend upon individual conditions. The fœtus in many women examined at the seventh month will be found with the breech presenting, but is born at full term with the occiput first.

The proportion of breech and transverse cases is much greater in premature than in full-term labors. But version just before labor is more difficult than it is several weeks earlier. If the amniotic fluid remains relatively large in amount up to the end of pregnancy, then version should be delayed to two weeks before labor, and *vice versa*; if the child is getting large enough to occupy so much space that turning will soon be difficult, then immediate version should be practised.

The possible dangers in version before labor are in the order given: Laceration of the amniotic membranes, of the placenta, cord, uterus, and indirectly from any of these death of the fœtus; labor may be precipitated. None of these dangers are at all imminent. In performing version, if the abdominal walls are tense from intestinal overloading, a half-drachm to a drachm of fl. ext. cascara sagrada will, by emptying the bowels, give more latitude in turning. Emptying of the bladder should never be omitted.

Gentleness, warm hands, cessation of effort during uterine contractions, and absence of all haste, will command success where opposite methods will cause failure and perhaps lacerations of the uterine contents. Anæsthesia is uncalled for. In converting a breech presentation into a cephalic, it will be found more difficult to pass the breech up out of the cervical segment than to bring the cephalic end down to the transverse diameter of the uterus, especially when the cervix rests well down in the pelvis. It may then be found necessary to elevate the intra-vaginal portion.

If it is a left sacro-anterior, the left finger should be introduced, and pressure made upward and to the mother's left, and *vice-versa* in a right sacro-anterior. In swinging the long diameter of the fœtus beyond the transverse diameter of the uterus, an assistant may prove useful by making pressure upon the fundus and cervix, with the object of increasing the transverse diameter. In sacro-posterior positions, rotation of the fœtal back to the front should be undertaken before attempting cephalic version, as it is easier to do in a breech presentation. If much difficulty presents in trying to lift the breech out of the pelvis, place the patient in the knee-chest position, and admit air into the vagina, thus permitting the uterus to fall away from the pelvic inlet. This aids in displacing the presenting part from out the inlet. There is a tendency in transverse positions for the head to glide to the fundus in the genu-pectoral position.

Rotation of the fœtal back to the front is difficult, from a want of leverage. The lower limbs afford the best purchase in rotation on the fœtal axis. If the fœtal back lies to the right posterior side of the uterus, the knees should be pressed downward and backward to the left posterior side. Then, while they are held here with one hand, pressure with the other should be made from as posterior a part as possible on the right side against the fœtal back, and effort directed to lifting it forward and thus over to the left. In performing version before labor we must, to avoid injuries, exercise extreme care not to use one point for pressure too long, or use too great force in displacing the fœtus. When labor has begun, these considerations are of less importance. Version accomplished, if before labor, there is no guarantee that spontaneous reversion to the previous malposition may not ensue. A study of the various causes of the malpositions in each case will aid in directing treatment for retaining the fœtus in place.

In hydrocephalic cases, the condition being recognized, if at all, by manual estimate through the abdominal walls, of the disproportionate size of the head, the frequency of breech presentations is said to be due to the decreased specific gravity of the head permitting the breech to gravitate to the pelvis. Such a cause could scarcely act late in pregnancy, so that version would prove lasting, except for the fact that here, as in contracted pelves, impaction of the head in the inlet is difficult, and much mobility prevails in the presenting part, shoulder presentations are apt to result. Not very much can be done to insure fixation. Mild compression of the lateral abdominal walls, by means of padded splints or bandages, will prove useful. In malpositions due to laxity in the uterine and abdominal walls, a supporter or bandage, such as that recommended by Pinard, which supports the entire abdomen and prevents sagging of the fundus, is needed. In hydramnios, where extreme distention of the uterus exists, bandaging is useless. But it is especially desirable in hydramnios to have an occipital presentation, as the child's vitality is poor, the uterus sluggish and weak, causing delay in breech cases that is very fatal to the child. Having obtained the desired fœtal position, the dangers of a bad result justify, if the pregnancy is within a couple of weeks of full term, artificial precipitation of labor.

Table of Cases of Version before Labor.

No. of Case.	No. of Pregnancy.	Period of Pregnancy.	Position of Fœtus.	Etiology.	Version.	Method.	Presentation when delivered.	Remarks.
1	Third	11 days before labor at full term.	Right sacro anterior.	Unknown.......	Cephalic to left occipital anterior.	Wigand's method. Both hands external.	Left occipital anterior.	First labor was a breech.
2	Second.....	12 days before labor a full term.	Right sacro anterior.	Short conjugate diameter.	Cephalic to left occipital anterior.	Wigand's method.	Left occipital anterior.	Lateral compresses were used for three days after version.
3	Second.....	In labor 2 hours; full term.	Right mento iliac.	Chest very large. Over 3 gallons of amniotic fluid.	Left occipital anterior.	Schatz's method ..	Left occipital anterior.	Head had to be held in place until forceps could be applied and traction enough given to get impaction of occiput, then forceps were removed. Child weighed 13½ pounds.
4	Fourth	5 days before labor at 8½ months.	Do sŏ anterior. Right shoulder.	Small child. Uterus very much relaxed.	Left occipital anterior.	Wigand's method.	Fœtus had returned to former position. Changed to left occipital anterior by Wright's method.	Child weighed 6¾ pounds.
5.	First	In labor at full term.	Right sacro anterior.	Unknown.......	Left occipital anterior.	Knee-chest position until the breech was displaced from the inlet; then dorsal position. Wigand's method.	Left occipital anterior.	Membranes ruptured unintentionally, but this did not prevent external version.
6.	Ninth	2 weeks before labor at full term.	Transverse dorso anterior. Right shoulder to left of inlet.	Unknown.......	Left occipital anterior attempted and given up.	Wigand's method.	....	Uterus was irritable, and fœtus rather immovable. Thought best to wait.
		Second trial. In labor at full term.	Right shoulder presenting, dorso anterior.	....	Left occipital anterior.	Wigand's method.	Left occipital anterior.	Head had to be held in place until fixed in pelvis by dilatation of os and rupture of membranes.

American Association of Medical Editors.—This body met in regular annual session at the Burnet House, Cincinnati, Monday, May 7, 1888. Meeting called to order by the President, Dr. William Porter, of the *Medical Review*, St. Louis, Mo. Dr. William C. Wylie, *New England Medical Gazette*, Danbury, Conn., Secretary, read the minutes. The question was propounded, "How far do Medical Journals distributed by Drug-houses and Manufacturers Interfere with Regular Medical Journalism?" This subject was discussed at length, from all points, by a number of gentlemen. This class of literature was condemned strongly, but many maintained that its effect upon regular journalism was not important. A new constitution and by-laws were adopted. The following officers were elected: President, Dr. W. C. Wylie, of *New England Medical Gazette*, Danbury, Conn.; Vice-President, Dr. Dudley S. Reynolds, of *Progress*, Louisville, Ky.; Secretary and Treasurer, Dr. J. C. Culbertson, *Lancet-Clinic*, Cincinnati; Censors, Dr. Richard J. Dunglison, of Philadelphia, Pa.; Dr. Young H. Bond, of St. Louis, Mo.; and Dr. William Davis, of St. Paul.

Progress of Medical Science.

The Antiseptic Injection of Inflamed Joints.—Dr. Hager advocates, in the *Deutsche Zeitschrift für Chirurgie*, the early use of antiseptic injection in a variety of cases of arthritis. He has used various liquids, but employs 1 : 20 carbolic-acid solution, or 1 : 1,000 sublimate solution, according to the character of the inflammation. He believes that a portion of the good effects realized from the use of the former fluid is due to its astringent property, and cites the practice of Dr. Schede, who has used it as an intra-articular injection in cases of habitual luxation of the shoulder-joint, and with excellent effect. He has himself cured a case of the well-known troublesome relaxation of the temporo-maxillary joint by a series of carbolic injections into the articulation, inserting them between the condyle and the zygoma, while the mouth was widely opened. Of 100 cases of hydrops articuli of the knee, a cure resulted in all but 1, who died of pulmonary tuberculosis a few weeks afterward. In only four instances was it necessary to repeat the injection and washing of the joint, although in nearly fifty per cent. of the cases the disease had existed for from one to ten years. Gonorrhœal arthritis he divides into two groups: 1. Those cases in which there is a pronounced exudation into the joints. 2. Those in which there is intense periarthritis with but trifling fibrinous effusion. His results were, as might be expected, especially good in the first class of cases, nine of which he treated by the injection method. In those of the second group they were, at least, as satisfactory as those attained by the usual methods. He details other cases of rheumatic, tuberculous, and fungous forms of arthritis of various joints, in which more or less complete cures were obtained in relatively very short periods of time. He dwells, in conclusion, upon the simplicity and safety of his method of treatment, which, even in those cases that might have been curable by other means, shortens the time required, and immediately relieves the joint of effusion which otherwise often persists for years.

In other cases incision and drainage would have been thought justifiable, but puncture and washing out answered the same purpose, with much less difficulty and danger. The operation is performed as follows: The region is cleaned and made absolutely aseptic; a trocar is introduced into the joint, together with a cannula fitting the syringe to be employed. After it is evident that it has entered the cavity, the trocar is withdrawn, the fluid evacuated, and the antiseptic solution injected forcibly and repeatedly until it issues clear and free from all mixture with blood or pus. It should be thoroughly diffused, so as to come into contact with the inner surface of the capsule at every point. Strong flexion and extension, made while the trocar-opening is closed with the fingers, and the joint half filled with fluid, aid in bringing this about. Some caution is necessary in performing this part of the operation, as it has happened to as distinguished a surgeon as Billroth to lose a patient by carbolic-acid poisoning from penetration of the intermuscular spaces of the thigh by the liquid forced out of the capsule by too vigorous movement. The little puncture is covered with an antiseptic dressing and the joint immobilized for eight or ten days, after which, at a time depending on the severity of the case, passive motion is begun. He gives details as to the best points of entrance of the various joints. The paper is a valuable contribution to this branch of surgery.—*The American Journal of the Medical Sciences*, April, 1888.

The Pathology of Infectious and Infective Diseases.—An instructive series of articles have recently been published in *The Lancet*, from the pen of the well-known pathologist Joseph Coats. The author states his conclusions as follows: "We have seen that, in the case of a large number of diseases of this class, inheritance, whether we take it more broadly in the race or more particularly in the family, has an undoubted and frequently a very great influence on the susceptibility to infection. This varying degree of susceptibility exists in the case of diseases which are demonstrably due to the action of micro-organisms, and we are driven to the conclusion that a micro-organism, which is pathogenic in the individuals of one race to a high degree, is non-pathogenic, or nearly so, in the individuals of another race. Recurring to our remarks on the general principles of inheritance, it seems necessary to relate this difference in susceptibility to fine differences in the structure and activity of the tissues. We have seen that the differences in the races depend on variations in the details of their tissues, such as singly might seem to be of comparatively little moment. The differences in individuals of the same race are still more minute, and depend on still finer variations in the details of the tissues. Coming to undoubted cases of inheritance of morbid conditions, we saw by illustrations that it was variations in the details of structure and function which are the subject of inheritance. In ichthyosis it is the structure and mode of growth of the epidermic cells; in hæmophilia it is the structure, presumably, of the blood-vessels; in Daltonism, the finer details of the structure and function of the retina. In all these cases it is the structure and activity of the finer elements of the tissues concerned which are at fault. When we find that the varying susceptibility to infectious and infective diseases is also related to inheritance, then we must, I think, relate it to the same kind of variations as those which we have found to be the subject of inheritance both of normal and abnormal structures. It is, again, the structure and vital activity of the elements of the tissues with which we have to do. If, as we have seen, the negro race differs very remarkably in its susceptibility to infectious disease from the European races, then we are led to believe that this depends on fine differences in the structure and activity of its tissues, such as determine the characters of race. It is the living active tissues with which we have to deal, and it is peculiarities in these, determined by inheritance, which, I believe, constitute the differences. Let us take it for granted that some at least of the diseases in question depend on micro-organisms. We know that the living active cells which compose the epidermic and epithelial tissues exercise an important influence in preventing the entrance of micro-organisms. Abundant bacteria are present on the surface of the skin and in the alimentary canal, but the epithelial and epidermic cells inhibit them, and prevent their entrance into the body—that is part of the function of these cells. Similarly, the cells of a granulating wound inhibit the bacteria which may swarm in the pus bathing the wound. These micro-organisms become dangerous when they are carried beyond these surfaces, as when perforation of the stomach or intestine occurs, or when decomposition takes place in a recent wound before granulations have had time to form. The living tissues beneath these surfaces have less power of inhibition, although still possessing it in some degree. It is only certain micro-organisms which will survive, even if introduced in the way mentioned. It is important to remember that each living tissue consists of an immense number of living active cells, each of which has its own vital processes. The micro-organisms also consist of living active cells, which possess an extraordinary power of multiplication by division. I believe we must look for the solution of the problem to the contending activities of the two kinds of cells. No doubt there are intricate chemical problems involved in all this. Each cell has its incomings and outgoings, and it is quite possible that it may be by means of some of the chemical products that the inhibition is effected; but of this we know nothing, and we can only associate it with the vital activity of the elements of the tissues. Of course, it is not to be inferred that inheritance is the only item in determining variations in susceptibility. We know that the same individual will at different times present remarkable variations in the degrees of susceptibility to the same morbific agent. I have chosen inheritance to illustrate the subject, because it appeared to me to offer examples which would serve to indicate the kind of influence concerned in the varying degrees of susceptibility to the class of diseases under consideration. If my remarks are justified by the facts which I have adduced, then I think there can be nothing contradictory in speaking of the varying susceptibility of different persons, or of the same person at different times, to the same infective or infectious disease. We can recognize in all such cases the action, on the one hand, of the morbific agent, and, on the other, the reaction of the living tissues."

PANCREATIC CARCINOMA IN CHILDREN.—Dr. Kühn has placed on record the history and post-mortem examination of a two-year-old female child that was affected with this disease. When the child was brought to him it was anæmic and troubled with constant diarrhœa. The child had been ill for several weeks before this time. Syphilis and other infectious diseases were absent. Physical examination revealed anasarca, slight bronchitis, general anæmia, stools yellow or rather brown in color, lymphatic glands and spleen not enlarged. Before death the stools became colorless and watery. Death ensued from pneumonia. The post-mortem revealed carcinoma of the pancreas with a metastatic deposit in the lower lobe of the left lung. Dr. Kühn concluded that the morbid growth must have commenced during fœtal life, as the disturbance manifested itself in the first year of its existence, after which the pancreas began to act more violently on the digestive organs. The dropsical appearance was caused by the pressure of the tumor on the venous circulation of the liver. The secretion of the bile was consequently diminished by the fatty degeneration of the liver, though not entirely suppressed. There was no jaundice.—*Berliner Klinische Wochenschrift.*

CREOLIN.—According to the Vienna correspondent of *The Lancet*, another antiseptic which Dr. Neudörfer has advantageously tried is creolin. This is a sort of tar which is obtained from the English pit coals by dry distillation, and from which the poisonous hydrocarbons have been eliminated. The chemical constitution is not yet established, but owing to its characteristic qualities it can be very easily recognized by the practitioner. It is derived from the aromatic class of hydrocarbons, and is closely related to creasote, carbolic acid, resorcin, hydrochinon, etc. The very first results which Dr. Neudörfer had obtained with this drug were very favorable, and he had for this reason at last abandoned all the other antiseptics and used only creolin. The first success he had obtained with it was in the case of a girl, aged seven, who suffered from erysipelas bullosum migrans faciei. The skin of the nose, the upper lip, and over both zygomatic arches was greatly stretched and much reddened; some pustules were also present. The lower eyelids were œdematous, the frequency of the pulse and the temperature were increased, and the patient also suffered from headache. Dr. Neudörfer said to the relatives that the erysipelas would spread over the forehead and the ears, and that it would disappear in from seven to ten days. He ordered a two per cent. solution of hydrocarbonate of sodium with syrupus simplex, and directed the erysipelatous parts to be brushed thrice a day with undiluted creolin. The erysipelas did not advance, the pustules dried up, the infiltration of the skin disappeared, and the patient ceased to complain of any pains. The symptoms of fever also disappeared, and the erysipelas was cured in two days and a half. Dr. Neudörfer has, since that time, tried creolin in two other cases of erysipelas with like success. In former times he used always to treat severe cases of erysipelas successfully with subcutaneous injections of carbolic acid, and he had therefore no reason to resort to the method of Krascke. Since he had tried creolin, however, he no longer used subcutaneous injections of carbolic acid, which had recently been again recommended by Fehleisen. The second case which had been antiseptically treated with creolin was that of a butcher, aged twenty-seven, who had cut the last phalanx of his left middle-finger and the terminal front of his ring-finger. After treatment with a two per cent. solution of creolin, and the application of creolin gauze, the wound healed, in eight days, without any suppuration or swelling. In the third case, in which a tumor in the region of the lower jaw was removed from a woman, aged thirty, creolin was used during operation and afterward as a dressing, two silk sutures closed the wound, and no drainage-tube was put in. On the third day the sutures were removed; the wound was already closed, and the dressing could also be removed. The author has since used creolin in several minor operations, both in the Polyklinik and in private practice, and has always observed that it relieved pain, checked the hemorrhage, and limited suppuration. At first he used a two per cent. solution, but he has now found that creolin is efficient in a one-half per cent. solution. Dr. Neudörfer prepares a fresh solution each time by adding two drops of creolin to seven ounces of water. He uses only ungreased gauze, which, being folded from ten to twelve times, is wrung out of the milky solution and applied to the wound, which is afterward covered with several layers of dry gauze. The dressing may be left until healing has taken place. This dressing is very convenient, both for the physician and the patient, and it is also very cheap. The surgeon's wards, the patient's skin, and the instruments can be disinfected with a two per cent. solution of creolin. Dr. Neudörfer concludes his paper by stating that he is so satisfied with creolin that he does not desire any other antiseptic. For country practice, as well as for use in war, creolin is, in his opinion, the most trustworthy and convenient, as well as the cheapest and most harmless antiseptic.

NON-CALCULOUS ANGIOCHOLITIS.—Hepatic suppuration may be due to many causes, and the channels of infection may be as numerous as the tubes entering the liver. M. Ferrand has recorded the case of a tailor, aged thirty-nine, who had been dyspeptic for two years, with increasing constipation and enlargement of the abdomen (*The Lancet*). Sudden attacks of pain and vomiting, with melæna, fever, and tender enlargement of the liver, were the chief clinical signs during the last month of his life. The necropsy exhibited a dilated stomach with slight ulceration of the large curvature near the pylorus. The liver was voluminous, presenting slight projections of its parenchyma, of dark-red color. The autopsy showed a multitude of disseminated abscesses varying in size from a hen's egg to a pea; the largest made a cavity at the root of the Spigelian lobe, and its walls were blackened, tomentose, and gangrenous. The majority contained a yellow-ochreous fluid, evidently composed of biliary matter; the gall-bladder appeared intact and filled with a similar liquid; nowhere could a calculus be discovered; the hepatic substance between the abscesses was of a red and granular aspect, due to a commencing cirrhosis. The case was therefore described as hepatitis with suppurative angiocholitis leading to peritonitis and melæna; the portal system appeared to be innocent of infection.

IODINE IN ASCITES.—Dr. Rivadeneyra, writing in *La Correspondencia Médica* on ascites due not to lesions of the heart, kidneys, or liver, but to the general condition of malarial poisoning, speaks highly of the success of iodine applications. He applies the tincture to the surface of the abdomen in strips or fringes, leaving a breadth of clear skin between each. The untouched parts are similarly painted when the iodine has caused the skin to begin to peel off. In cases where the ascites is very considerable, paracentesis is first performed, and the iodine applications commenced a few hours afterward.

A MAN has been condemned at Carlsruhe for inducing hypnotism in a young man, nineteen years of age. The court regarded it as a case of assault.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place

New York, May 26, 1888.

SOME NEW STUDIES OF THE CARDIAC MOVEMENTS.

MARTINS has made a series of careful and ingenious experiments with the cardiograph, as the result of which he has perfected the instrument, and corrected, as he believes, some errors in the conclusions of previous observers.

The cardiograph is an instrument which has heretofore been little employed in clinical medicine, and it is not likely to become widely used. But it is not difficult of application, and if it can furnish more exact data in obscure cases the fact should be known and taken advantage of. For this reason, we call attention to the subject now. The articles of Martins, published in the *Zeitschrift fur klin. Medicin*, Bd. xiii., Heft 3–6, and in the *Deutsche medicinische Wochenschrift*, No. 13, 1888, are lengthy and technical. We cannot attempt to give even an outline of the author's line of argument, but shall only refer to his results.

There has been considerable difference of opinion among the physiologists Marcy, Landois, Ott, Ziemssen, and others as to the proper interpretation of the cardiogram.

The first part of the tracing produced by placing a cardiograph over the position of the apex-beat consists of a rather sharp ascent, followed by a rather sharp descent. The line of ascent, says Martins, marks the period of the contraction of the ventricle upon the blood which fills its distended cavity. At the moment that the line reaches its highest point the semilunar valves open, and during the descent of the line the blood rushes into the arteries. The systole of the heart is represented by a curve, therefore, consisting of a line of ascent and descent. The ascent marks what Martins calls the systolic closure-time; the descent, the time of the "heart-aortic-stream." This latter line is longer or shorter, according to the amount of pressure in the arteries or the obstruction at the aortic valves. Its course, therefore, is clinically of value in studying arterial pressure or stenotic conditions. A second and smaller curve now follows, whose apex corresponds to the closure of the aortic valves. This curve would be disturbed in regurgitation. Following this, the cardiographic line sinks, corresponding with the relaxation or diastole of the heart. But the diastolic fall is interrupted by an impulse due to the backward impact of the blood on the aortic valves after the arterial systole is completed.

There are therefore three distinct elevations in the cardiographic curve. If the interpretations placed upon them by Martins are correct, a study of their variations in valvular and arterial disease may furnish data of practical interest to the clinician.

THE CLASSIFICATION OF THE DYSPEPSIAS.

THE term "dyspepsia" is rapidly being relegated to the realm of old-fashioned and mystical pathology. It can no longer be used by exact clinicians, except when carefully qualified. To be sure, there are many cases yet in which the particular form of functional stomach disorder from which a patient suffers cannot always be diagnosticated. But such cases are diminishing in number, and the physician who makes a diagnosis of dyspepsia, without further inquiry, must be put down as a loose and careless observer.

There is little excuse, for example, in failing to recognize decided gastric catarrh, or well-marked dilatation. The determination of the functional disturbances is constantly being made easier.

Dr. Julius Glax, in a recent work (*Ueber die Neurosen des Magen—Klinische Zeit- und Streitfragen*, Band 1, Heft 6), has done excellent service in presenting systematically the knowledge so far accumulated regarding many of these different forms.

In fact, under neuroses of the stomach may be included nearly every gastric disorder of a functional kind.

His classification will interest our readers, in showing, if nothing more, the refinement in symptomatological analysis which recent observations have made possible. The classification is as follows:

Group I. Motor neuroses. (a) Hyperkinesis, or irritative forms: (1) Peristaltic and antiperistaltic mobility of the stomach; (2) morbid eructations, belching, etc.; (3) nervous vomiting; (4) cramp of the stomach—general—of cardia, and of pylorus. (b) Hypokinesis, or depressive forms: (1) Atony of the stomach; (2) insufficiency of cardia, regurgitation, merycism; (3) insufficiency of the pylorus.

Group II. Sensory neuroses: (1) Cardialgia, central, reflex; (2) changes in the physiological sensations of hunger and satiety—anorexia nervosa, or gastric hysteria, bulimia, parorexia, or perverted sensations of hunger.

Group III. The secretion neuroses: (1) Irritative forms, hyperacidity, nervous gastroxyusis; (2) depressive forms, deficient secretion.

Besides the above, there occur, no doubt, vaso-motor disturbances, but their independent existence can hardly be recognized. It happens, practically, that many of the above disorders may be united, and that some of them may complicate inflammatory or other organic changes. At the same time, many typical examples of the special forms enumerated are on record and are not difficult to recognize.

INTRAPLEURAL INJECTIONS OF STERILIZED AIR IN THE TREATMENT OF PNEUMO-THORAX.

MUCH interest has been aroused over the presentation by Professor Potain, before the Académie de Médecine, of a patient whom he had cured of pneumo-thorax by the injection of sterilized air. Such a statement seems at first paradoxical, but an account of the case explains it.

The patient, twenty-three years of age, suffering from incipient phthisis, was suddenly attacked with fever, which lasted fourteen days and was accompanied with extensive pleuritic effusion, accompanied, at first, with air in the pleural cavity. As the effusion increased the lung became compressed, and the opening connecting it with the pleura was closed. The effusion finally reached the fossa supraspinata, and the patient's condition called for interference. If the effusion were withdrawn, however, it was thought probable that the connection with the lung would be opened, and the pneumo-thorax would reappear. Professor Potain therefore devised an apparatus, in the shape of a double cannula connected with a manometer, by which, as fast as the liquid was withdrawn, sterilized air took its place. The air was sterilized by being passed through cotton and then through a strong solution of carbolic acid. During the next three months the fluid, which was slightly purulent from the first, was withdrawn twice more. The amounts removed were fourteen hundred, sixteen hundred, and five hundred cubic centimetres. The patient gradually improved, his original pneumo-thorax did not return, and even his tuberculous symptoms disappeared, so that he was discharged cured. Two other cases were treated in a similar manner, one being cured and the other improved.

Professor Potain thinks that his results quite justify him in recommending this new procedure in appropriate cases. It allows one safely to remove a large amount of liquid from the pleural cavity, and thus obviate the danger of repeated evacuations and of producing congestions and rupture of the lungs from sudden expansion.

The prognosis of pneumo-thorax ordinarily is very bad. Among 46 cases of tuberculous origin collected by Professor West, of Heidelberg, 44 died and 2 were cured. Among 11 previous cases of this disease observed by Potain, 8 died and 3 were cured.

AUXILIARY PUBLIC SCHOOLS FOR FEEBLE-MINDED AND BACKWARD CHILDREN.

In several of the larger German towns auxiliary schools have been established for the benefit of children who are unable to bear the strain of the ordinary curriculum. Describing them the *British Medical Journal* says: "Those children who after two years' trial have been shown to be quite unable to follow the instruction given in the classes of the national schools are drafted into these special schools, where, all the pupils being on about the same intellectual level, it becomes possible to place them under the charge of a specially trained teacher, who instructs them in classes not exceeding twenty members, so that some care may be devoted to their individual capacity and requirements. This withdrawal of the feeble and more backward children from the national schools enables more care to be given than to the ordinary children working in the curriculum, a heavy incubus and tax upon the teachers' time being thus removed."

The German schools have been successful, and the *British Medical Journal* urges the adoption of the system elsewhere. It certainly meets a practical want. The only question which arises is, whether the State should undertake to educate the defective classes as well as the healthy. We believe that it should, and that such policy would be the most humane and economical in the end.

THE THERAPY OF GONORRHŒA.

Dr. E. Finger, of Vienna, contributes to the *Internationale klinische Rundschau*, 1888, No. 19, an article upon "some new antiblennorrhagics," in which he shows apparently that Vienna physicians are a little behind the Western world in the treatment of gonorrhœa. Dr. Finger, like most German physicians, accepts the specific bacterial pathology of this disease, and remarks truly that our therapeutics have not advanced in the same measure as our pathology.

Among what Dr. Finger calls recent internal remedies are two which he thinks are of especial value, viz., sandalwood oil and kava-kava. The former, he finds, possesses the same value as copaiba, but has the advantage of not irritating the stomach. He gives it in five-grain capsules, of which four to six are taken daily. The kava-kava is given in doses of twenty to thirty drops of the fluid extract. The indications for both drugs are the same. They are to be given in acute urethritis, anterior or posterior, and in acute urethro-cystitis. Both are contraindicated in the very severe forms of urethritis, the so-called "phlegmonous gonorrhœa."

With regard to topical measures, Dr. Finger speaks in the highest terms of lanolin ointments. Lanolin has the advantage of being aseptic and antiseptic, and also of being absorbed by the mucous membrane, carrying deep into it, therefore, the active agent with which it is united. The ointment is applied by means of a specially constructed syringe, which consists of a catheter—No. 16 to 18—with a single opening at its vesical end. In this is fitted a piston, the whole holding about one decigramme of ointment. Lanolin ointments are indicated only in the ordinary acute forms of gonorrhœa, and not in the chronic types. The formula given by Finger is as follows:

℞.	Nitrat. argenti vel cupri sulph. .	Gm. j. to iij.
	Lanolin	Gm. xcv.
	Olei oliv.	Gm. v.
M.		

In obstinate cases the following is recommended:

℞.	Potas. iodid	Gm. v.
	Iodin.	Gm. j. to iij.
	Lanolin	Gm. xcv.
	Olei oliv.	Gm. v.
M.		

Dr. M. A. Castellan (*Arch. méd. Belges*) has been making some experiments with alkaline injections in gonorrhœa. It has been observed that the gonococcus thrives in acid media, hence he employed eight to ten per cent. solutions bicarbonate of soda three or four times daily. In old cases, in which other remedies failed, the alkaline medication "led to rapid and complete recovery."

Dr. Turpura Impallomenti has been employing one per cent. solutions of creasote in decoction of camomile. His results are, that "five out of seven patients were cured in six days."

Dr. Rohé is quoted by the *Maryland Medical Journal* as recommending ten per cent. dilutions of liquor sodæ chlorinatæ. He finds that "the discharge promptly ceases in the majority of cases."

L'Union Médicale, 1886, p. 664, gives a number of formulæ which are highly recommended by "M. Jones" in the *Rev. de thér. gén. et therm.*, 1888, No. 13. These formulæ amount to little more than those of the Lafayette mixture and weak solutions of sulphate of zinc. We are inclined to think that, after all is said, these two preparations will accomplish as much as any of the therapeutic novelties in the vast majority of cases of gonorrhœa.

THE SANITARY PROTECTIVE LEAGUE.

UNDER this name an organization was formed in this city three years ago, for the purpose of assisting the health-authorities in case of emergency. Members of the society, co-operating with medical and other organizations, secured, in 1887, the passage of important amendments to the tenement-house law and also of the small parks bill.

The league has now been revived again, and proposes: (1) to encourage work in the inspection of tenements, factories, and workshops, and report defects; (2) to employ a corps of women visitors to distribute sanitary tracts, and to teach the poor how to keep their health; (3) to encourage tree-planting and additional small parks; (4) to establish hot public baths for winter use; (5) to encourage the formation of building associations for the erection of small houses for working-men in the suburbs.

These are all objects that deserve a hearty support from those interested in promoting public health and in improving the condition of the poor. Certain figures are given which accentuate this fact: "Some sixteen thousand children under five die every year in New York—just twice the normal mortality for a large city. Last summer four thousand one hundred and nineteen were carried off, and nearly a thousand in a single week—a larger number than in any year since 1872. If viewed rightly, this would be called simply massacre.

"The deaths from diphtheria have doubled in four years (from 1884 to 1887). If cholera were as frequent and fatal, the city would be deserted in a panic."

Just now one would think that the stability and happiness of society depended on the question of a tariff. In reality, we believe that wise sanitary reforms would have a vastly greater influence in saving money and promoting happiness and morality in the nation than the reduction of duty on wool. A truer sense of proportion will doubtless in time be educated into the minds of those who are presumed to mould public opinion. Meantime, we wish success to every sincere effort to promote sanitary reform, and the Sanitary Protective League is one of these.

MIDWIVES IN CLEVELAND, O.—According to the Cleveland *Medical Gazette* there are in that city nearly fifty midwives, mostly Germans, with a number of Bohemians and a few English. "As to qualification, nine-tenths of them have no training whatever, and too many of them have not the recommendation of habits of common, decent cleanliness. A large percentage of the cases of puerperal septicæmia which occur in the city are in the practice of the midwives, and innumerable instances of mismanagement and malpractice occur which never meet the light of investigation, as one may fairly judge by the occasional cases that do come under the observation of physicians." In Ohio, anyone can practise medicine or be a midwife by simply announcing themselves.

News of the Week.

TAKING THE THERMOMETER AND LOSING THE TEMPERATURE.—An Italian patient in one of Dr. Shrady's wards in St. Francis Hospital, deliberately chewed a fever thermometer and swallowed the greater part of it before he was made to understand that the instrument was not intended as a medicine. Luckily, he has had no subsequent increase of temperature, which would make it necessary to risk another thermometer in that way. The rectum will be the next choice.

CALIFORNIA needs laws providing for compulsory vaccination of school-children, and for burial of human bodies only upon the authority of a death-certificate. At the last meeting of the State Society the following resolutions were passed:

"That the Society cordially indorse the efforts of the State Board of Health in their endeavors to procure a law to forbid interment and cremation of human bodies in this State without first having obtained a permit from some proper constituted authority; and also,

"That the Society cordially indorse the efforts of the State Board of Health in their endeavor to procure a law whereby vaccination will be compulsory upon all children entering the public schools, and also in their endeavor to make the law relating to the registration of births, marriages, and deaths effective.

THE LITERARY MACHINE FOR INVALIDS.—It will interest the innumerable admirers of, and sympathizers with, the illustrious German invalid to learn that his comfort has been considerably enhanced by a cleverly constructed apparatus for holding books over a bed, known as the literary machine, which the Kaiserin had herself ordered from the London inventor.

THE LATE DR. EDWARD G. LORING.—At a regular meeting of the Practitioners' Society of New York, held May 4, 1888, it was

Resolved, That in the death of Dr. Edward Greely Loring the Society has lost an eminent colleague, whose contributions to its scientific work were characterized by distinguished ability; whose agreeable companionship contributed largely to the enjoyment of the social entertainments of the Society; and whose absence will long be felt and lamented.

Resolved, That these expressions of regret be entered on the minutes by the Secretary, and that he be requested to furnish a copy of the above resolutions to THE MEDICAL RECORD and Journal for publication, and to send a copy to the family of Dr. Loring, with the sympathy of the members.

SAMUEL SEXTON,
ROBERT F. WEIR,
JAMES B. HUNTER,
Committee.

A NOVEL REASON FOR DECLINING A CONSULTATION.—Professor Kremianski, says *The Lancet*, has recently been invited to take a journey from his residence in Kharkoff in Russia to Xeres in Spain, to attend a consultation in a case of phthisis, the local physicians being disposed to employ his system, which is sometimes, though not very correctly, described as the "aniline treatment." This consultation the professor has declined, on the ground that until his work, entitled "Zarasy i Chakoti" (Infections and Phthisis), which at present exists only in Russian, is translated into some language which the Spanish physicians read it would be useless for him to go such a distance, as his proposed consultees cannot be fully acquainted with the principles on which his treatment is based. He therefore foregoes a very large fee on a somewhat novel ground.

THE MUCH ADVERTISED QUACK MEDICINE, VITA NUOVA, according to the *Boston Journal of Health*, is nothing probably but a native port.

THE PRACTITIONERS' SOCIETY OF NEW YORK, at its last annual meeting, elected Dr. F. P. Kinnicutt President.

A PROVIDENT MEDICAL ASSOCIATION.—A Medical Aid and Co-operative Society has been started in Brooklyn. It has established a graded scale of weekly, monthly, and quarterly dues, according to the ages of members and the number contained in the family, and the prompt payment of which is in lieu of fees for all medical services, surgical and obstetrical services not being included.

THE MICHIGAN STATE MEDICAL SOCIETY will meet in Detroit on June 14th and 15th.

BLOOMINGDALE INSANE ASYLUM TO BE MOVED TO WHITE PLAINS.—The Society of the New York Hospital has resolved upon a removal of the Bloomingdale Insane Asylum to White Plains, the demolition of all the buildings now composing the asylum except the Mrs. John C. Green memorial building, and the sale at auction by lots of the tract now occupied by the asylum for building purposes. The sum of $1,000,000 has been appropriated by the managers for the new building. The present grounds will make about five hundred and fifty-eight city lots, the amount received from the sale of which it is estimated will bring in an income of $200,000, quite enough, it would seem, to run the new asylum. The Green memorial building is to be left, and will probably be utilized as a general hospital. The present site of the asylum was purchased seventy-two years ago for $4,000. It is now worth at least $3,500,000.

THE "CHRISTIAN SCIENTIST," Mrs. Abbie H. Corner, of Malden, Mass., whose daughter and daughter's infant died in childbirth, is being tried for manslaughter. The evidence seems to show that the woman neglected to provide proper medical care for her daughter, but continued praying over her until death occurred. Exactly similar cases have at times come before the English courts. In London, there is a "Peculiar People" who believe in prayer and laying on of hands, but in no medical or surgical treatment. Occasionally the leg of a peculiar person gets broken, or a fever attacks him. If death occurs, the law steps in, as in the Malden case, and it has, so far, decided against the Peculiar People.

THE JOHNS HOPKINS HOSPITAL, at Baltimore, is said to be now completed, and it will be formally opened next fall. The hospital is probably the costliest and most complete in every detail of any institution of the kind in the world. The total number of the buildings is now twenty-three, and their cost has reached among the millions.

A CHINESE SURGEON, named Leon Jack, has recently arrived in this city and established himself.

A NOVEL EXTENSION OF THE USE OF COCAINE.—Mr. E. Hurry Fenwick claims that strong (twenty per cent.) solution of cocaine, injected in small amount into the urethra, will relieve renal, lumbar, and other pains due to slight irritations. The drug acts by reflex inhibition.

THE ENGLISH medical world is shouting with laughter. The last edition of *Fun* speaks of the Galen Club, of London, as a place where doctors may be found "re-Galen" themselves.

THE DONDERS MEMORIAL FUND has reached the sum of $10,000. Professor Donders' seventieth birthday is on Sunday, May 27th; the presentation of the fund to him will be made on the 28th.

ST. ELIZABETH'S HOSPITAL, of this city, formerly, if not now, under the charge of Sisters of the Third Order of St. Francis, is reported to be lapsing into desuetude, owing to some technical religious troubles among its managers. The hospital was at one time a very prosperous one.

MEDICAL OPINION IN ST. LOUIS.—St. Louis seems to be one of those ideal spots in which politicians actually pay some respect to medical opinion. The mayor appointed as health-commissioner a physician of high standing recommended by the St. Louis Medical Society. This society has formally thanked him, and the St. Louis doctors are thinking of putting up a candidate for President of the United States.

THE EMPEROR OF GERMANY has his temperature taken by a half-minute thermometer placed in the mouth. Professor Leyden insists on his eating grape instead of cane sugar.

THE LOUISIANA STATE MEDICAL SOCIETY ON CONTRACT PRACTICE.—At its recent annual meeting the Society passed the following resolution, which has the triple merit of brevity, candor, and truth:

Resolved, That we regret that physicians do contract practice, but the Society cannot do anything to prevent it. Adopted.

THE OVARIES AND THE SEXUAL SENSE.—Certain laparotomists, whose specialty is removal of ovaries, have claimed that such removal does not affect the sexual or maternal feelings of the patient operated upon. Evidence, so far, has come mainly from the gynecologist-operator. Dr. John W. Taylor, in the *Birmingham Medical Review*, cites an illustration of the bad effects of the operation on the natural instincts of the woman. The question is, at any rate, not to be considered settled by the apodictica of our operating oöphiles.

THE BEST ANÆSTHETIC in obstetrical practice, according to Dr. Stephens, of Brighton, is a mixture of equal parts of alcohol and chloroform, to which may be added, if desired, a little cologne water.

THE ILLNESS OF DR. FRANK P. FOSTER.—We learn with deep regret that our friend, Dr. Foster, editor of the *New York Medical Journal*, is suffering from an attack of perityphlitis. Fortunately, the symptoms have not assumed a grave aspect, and there is every reason to hope that his valuable life will be spared.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Thirty-ninth Annual Meeting, held in Cincinnati, O. May 8, 9, 10, *and* 11, 1888.

SECTION ON DERMATOLOGY AND SYPHILOGRAPHY.

Tuesday, May 8th—First Day.

L. D. Bulkley, M.D., President, in the Chair.

At the opening session the question proposed for discussion was

THE ETIOLOGY AND TREATMENT OF ECZEMA.

Dr. L. D. Bulkley, of New York, said that the causes of eczema were twofold, viz., internal and external, and each of these might be again divided into predisposing and exciting causes. Among the internal causes, the predisposing were heredity and various diatheses—the rheumatic, gouty, strumous, and neurotic—and the exciting cause was lowered vitality resulting from overwork or worry, or from digestive disorders and consequent malassimilation. Of the external causes, the most active were climate, occupation, diet, and external irritants.

Dr. Zeissler, of Chicago, referred to the opposing theories concerning the etiology of eczema which were held in Germany and in this country and England. In the former, the predominant theory, most strongly upheld by Hebra, was that eczema is due to purely local causes, and very strong arguments, derived from the results both of experiments and of therapeutics, were advanced in support of this theory. The view most generally held in this country was that eczema is a constitutional affection, but the speaker thought that this was too sweeping, and he was of the opinion that there was a measure of truth in both these theories. It was possible that the disease was due to the

PRESENCE OF MICRO-ORGANISMS;

but if this were so, there must be a large number of these, and consequently it would be necessary to subdivide the affection into several distinct diseases.

As to treatment, the speaker favored the use of internal remedies, but he did not rely upon them to such an extent as formerly. He used arsenic only in the dry form of chronic eczema.

Dr. Shoemaker, of Philadelphia, thought that the rheumatic element in eczema was often ignored. He had seen a number of cases in which benefit had followed the administration of

ARSENIC IN SUPPOSITORIES AND HYPODERMATICALLY,

after the remedy had been given by the mouth without relief. He had also seen remarkable results, in certain cases, follow the employment of massage or electricity. The latter might be given in the form of either galvanism or faradism.

Dr. Ravogli said that it was very necessary to take into consideration the individual characteristics of the patients, their age, the normal condition of their skin, their constitutional tendencies, etc. The symptoms of eczema varied greatly according to the age of the individual, the general tendency being to acute manifestations in infancy, and to a more chronic form in the aged. Anything which interfered with the circulation of a part might act as a cause of local eczema. He thought the disease might well be characterized as a

CATARRH OF THE SKIN.

In the eczema of infancy he had obtained good results from resorcin and salicylic acid.

Dr. Reynolds, of Chicago, relied chiefly upon the

LOCAL TREATMENT OF ECZEMA,

which was soothing or stimulating according to the nature of the disease. He did not, however, neglect constitutional treatment, which was sometimes of very great importance.

Dr. Ricketts, of Cincinnati, had observed a number of cases of eczema in which the urine was found to be highly acid. He was unable to say whether there was any more than an accidental relationship between these two conditions.

Dr. Fleischner, of New Haven, was a firm believer in

ARSENIOUS ECZEMA.

He used arsenic to some extent, but less than in former years.

Dr. W. T. Corlett, of Cleveland, then read a paper on

PRAIRIE ITCH.

There are four features, he said, which are supposed to distinguish this affection: 1, Itching; 2, an eruption; 3, the alleged presence of a parasitic organism; and, 4, the rebelliousness of the affection to antiparasitic remedies. He reported a number of cases, which had come under his observation, of the so-called prairie itch, or lumberman's itch, and came to the conclusion, as a result of a careful study of these cases, that there was no morbid entity which could be called by a separate name, but that the designation had been bestowed, at one time or another, upon almost every affection of the skin which is accompanied with pruritus. The inevitable conclusion was, that practitioners in general were lamentably weak in their powers of diagnosis of cutaneous disorders.

In the discussion which followed, the speakers were in accord with the author of the paper in denying the existence of such a disease, and they thought that the name was only a cloak for the ignorance of the medical adviser.

Wednesday, May 9th—Second Day.

The subject for discussion at this session was announced to be

THE LIMIT OF THE PERIOD DURING WHICH SYPHILIS CAN BE COMMUNICATED BY CONTAGION OR INHERITANCE.

Dr. L. B. Bangs, of New York, had sent a letter in which he concluded, from a study of a number of cases collected by Fourrier, that (1) the so-called tertiary lesions of syphilis are not contagious; (2) the contagious period of syphilis may disappear spontaneously; and (3) the extreme limit of the contagiousness of the disease may be put at five years. He cited several authorities who were inclined to put the limit of contagion at a much earlier period than this. Another argument in support of this view was that derived from

REINFECTION.

A person who is capable of contracting the disease a second time may reasonably be supposed to be so far cured as to be unable to communicate syphilis to another. The writer instanced eleven such cases, the average period at which the reinfection occurred being about five years after the beginning of the first attack.

Dr. Keller reported a case which had come under his own observation. A man married within a few months after having contracted syphilis, and had mucous patches in the mouth some time later. The wife remained perfectly well during her pregnancy, but the child had sniffles immediately after birth, and soon presented a skin eruption. Ten days after its birth the mother presented a well-marked macular eruption over the entire body. The children born subsequently showed no evidences of syphilis.

Dr. Palmer, of St. Louis, did not think that any definite time could be set as the limit of the contagiousness of syphilis.

Dr. Ohmann Dumesnil, of St. Louis, read a paper entitled

DOUBLE CHANCRE À DISTANCE.

He reported two cases, in each of which there were two well-marked hard chancres, one on the prepuce and the other on the lip. Both patients suffered from cracks in the lips. The speaker did not regard the cases as examples of auto-inoculation, but believed that the two chancres had been acquired at the same time, since they were apparently of the same age, the induration and glandular enlargement appearing and disappearing simultaneously.

The speaker then reviewed the evidence for and against the possibility of

AUTO-INOCULATION OF SYPHILIS,

closing his review with the following conclusions:

1. The probability of auto-inoculation in early syphilis has not been demonstrated.
2. While there may be strong presumptive evidence in favor of it, it is only at best a possibility.
3. The most crucial experiments prove that excision of the chancre, at the earliest possible moment, is futile and falls short of its purpose.
4. In multiple chancres *à distance* the lesions are due to the same inoculation, as a rule.
5. In multiple chancres of different ages, it is probable that the younger lesions are merely irritative scleroses.
6. Experiments, so far, apparently prove that syphilis is constitutional at the time the initial sclerosis makes its appearance.

Dr. Palmer, of Louisville, did not believe that syphilis was auto-inoculable, and thought that excision of the chancre was useless as a therapeutic measure.

Dr. Ravogli had seen two cases in which there was a double chancre of the penis, one on each side. He saw no valid argument against the auto-inoculability of syphilis, and he believed that early excision of the indurated chancre would, in many cases at least, prevent a generalization of syphilis. He had performed excision in six cases, and in no instance did the patients present any further manifestations of syphilis, although no other treatment was resorted to. The operation was very simple, and was well worth trying in the light of the results which he had obtained. Care should, of course, be taken to remove thoroughly all the indurated tissue.

Dr. Zeissler, of Chicago, did not believe that excision would prevent syphilis, and those cases in which it had seemingly done so were to be explained by the fact that the constitutional disease did not always follow the appearance of a hard chancre. He had seen a number of such cases, and had also met with others in which the disease followed a chancre without any induration.

Dr. Keller, of Hot Springs, believed in the value of excision, but to be effectual it must be practised within forty-eight hours after the appearance of the lesion.

Dr. Reynolds had no faith in excision, for he did not look upon the evidence alleged in its favor as at all conclusive.

Dr. Palmer thought excision was of sufficient value to at least warrant its execution. He did not think it would cure the syphilis, when once induration had taken place, but he believed that it would lessen the severity of the subsequent symptoms.

Dr. Ohmann Dumesnil said that the mere fact that no secondary symptoms were noted after excision of the chancre proved nothing, for often the secondary manifestations of syphilis were so slight as to escape notice.

Dr. Joseph Zeissler, of Chicago, then read a paper on the importance of the

LOCAL TREATMENT OF SYPHILIS,

which he thought was often underestimated. He had found mercurial plaster useful in promoting the disappearance of the induration. For the roseola he used white precipitate ointment, of a strength of from ten to twenty per cent. Chrysarobin had been recommended for the cure of the papular syphilide of the palms and soles, and for the moist condylomata he had found nothing better than the solid nitrate of silver. The best results of local treatment are seen in the later manifestations.

Dr. Shoemaker, of Philadelphia, was partial to hot baths of water, steam, or air. He had found chromic acid very useful as an application to the mucous lesions.

Dr. Ohmann Dumesnil had obtained excellent results from the use of nitric acid in the treatment of syphilitic lesions of the anus and vulva.

Dr. Keller had found

THE ANIMAL FATS

much better than the mineral as bases for ointments, and he now never made use of vaseline for this purpose.

Dr. Palmer wished to emphasize the remarks of the last speaker, for he had found that the presence of animal fats increased very appreciably the efficacy of ointments.

Thursday, May 10th—Third Day.

Dr. H. J. Reynolds, of Chicago, read a paper on

THE GALVANIC METHOD OF TREATING VEGETABLE PARASITIC DISEASES OF THE SCALP.

The explanation of the want of success in the ordinary methods of treating these diseases was that the remedy could not reach the hair-follicles and destroy the fungus there situated, and his method was designed to effect the penetration of the parasiticide. After having washed the parts, he applied the positive sponge electrode, wet with a one per cent. solution of corrosive sublimate, for about ten minutes, the negative electrode being placed at any indifferent point in the neighborhood. Any other efficient parasiticide might be used in place of the bichloride. The strength of the current varied according to circumstances, the main point being to apply as strong a current as the patient could bear. He had read a paper on this subject before the International Medical Congress, and since that time had had two additional cases. Eight other cases had been reported by Drs. Charon and Gevaert, of Brussels. In all of these a cure had been obtained within three weeks, on the average, although several of them had persisted, in spite of active treatment by the old methods, for years. He believed that this plan solved the problem which had so vexed dermatologists of how to cure parasitic diseases of the scalp.

SECTION ON STATE MEDICINE.

Dr. Henry B. Baker, of Lansing, Mich., Chairman of the Section, delivered the annual address, taking as his subject

RECENT ADVANCES IN STATE MEDICINE.

At the present day, he said, sanitarians may be characterized as disease-preventers rather than nuisance-abaters. Public health officers are becoming in a greater sense instructors, and are less dogmatic and mandatory in their methods than they formerly were. An evidence of progress is seen in the constantly increasing number of sanitary publications and in the more frequent articles on State medicine which appear in the medical journals of the country. The work done by State Boards of Health in spreading among the people knowledge useful in the prevention of the most dangerous diseases is productive of great and immediate good, as is evidenced by the decrease of mortality from preventable diseases.

ORGANIZATION

of those interested in sanitary matters is of great importance, and the steps in that direction which have been taken in many of the States are a hopeful sign of growing popular interest in these subjects. The

NATIONAL CONFERENCE OF THE STATE BOARDS OF HEALTH,

which had just been held in Cincinnati, was not intended to supplant the older American Public Health Association. Its work differed from that of the latter body, being largely concerned with practical questions of public health, and its membership was restricted to officers of health boards, who are in position to put into practice the conclusions reached by the Conference.

The speaker then referred to

LOCAL, STATE, AND NATIONAL LEGISLATION,

the most important part of which was that relating to the collection of facts. It was a cause for regret and for shame that the Government of the United States is apparently less concerned about human health and life than it is about protecting swine and domestic animals from disease. It is behind all other governments in this respect. It is true

THE NATIONAL BOARD OF HEALTH

was established in 1878, and for a time it did excellent service, but it was opposed by some of those in power in Washington, who finally succeeded in crippling it by cutting off the needed appropriations. In Germany and some other countries bacteriological laboratories are maintained by the government, but here the only opportunities for study of this new science are found in a few of the larger medical schools.

Dr. Barker then spoke of the results of

BACTERIOLOGICAL STUDIES

as shown in the new views concerning the nature of typhoid fever, summer diarrhœa, and other diseases.

Great progress has apparently been made in warding off certain diseases by means of

QUARANTINE.

This service in New Orleans has reached a high state of perfection, and even in New York, although the system of that port has been severely criticised, good work has been done during the past year in preventing cholera from gaining a foothold. The cry is now for the general Government to take charge of quarantine at all the ports of the country; but the speaker did not think that past experience in national sanitary legislation held out much hope that such a change would be an improvement, and he preferred to leave the control of such matters where it now rested, at least until the general Government showed itself to be capable of doing the work.

In conclusion, the speaker advocated the collection and publication of statistics of sickness as well as of mortality, and he believed that much could be learned from a comparison of such figures with the records of temperature changes and atmospheric conditions.

Dr. Benjamin Lee, of Philadelphia, read a paper entitled

SHOULD NOT THE NATIONAL GOVERNMENT DEFEND OUR PORTS AGAINST THE NATIONAL ENEMY, CONTAGIOUS DISEASE?

It would seem that there could be but one answer, and that an affirmative one, to such a question; yet the proposal had been opposed by many, some of whom were influenced, possibly, by local interests or sectional jealousy. It had been contended that quarantine was a police regulation, and, as such, belonged to the various States to enforce. But Congress has the power to provide for the general welfare as well as for the common defence of the United States, and the term "common defence" might be more liberally interpreted than as referring solely to protection against the armies and navies of foreign countries.

MILLIONS OF DOLLARS

have been expended for the defence of our coast line, and millions are yet to be spent, but nothing can be of more importance than to protect the entire nation from pestilence introduced from without. During the past twenty years the assaults of foreign contagion have cost this country more lives than were sacrificed in the great war immediately preceding that period, yet most of these lives might have been saved by the expenditure of a sum which is insignificant as compared to what has been spent on coast defences, the navy, etc.

When quarantine was regulated by the local authorities all stations could not be of equal efficiency, but the weakness of one was a source of danger to the whole country. A port of limited commerce could not afford to spend as much for its quarantine as a larger and wealthier place, and the only remedy for this inequality was the assumption of the entire regulation of the matter by the national Government.

A NATIONAL QUARANTINE,

properly conducted by trained officials, would tend to prevent panic, allay undue anxiety, and favor a reasonable sense of security. It would do away with the necessity for the vexatious temporary

INTERSTATE QUARANTINES

which so seriously disturb inland commerce.

In conclusion, he begged leave to offer the following resolution: "That the Section on State Medicine respectfully suggests to the American Medical Association the importance of formally urging upon the National Congress the duty of at once assuming entire control of the maritime quarantine, and taking immediate measures to make such quarantine effective before the advent of hot weather."

SECTION ON PRACTICAL MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

Wednesday, May 9th—Second Day.

The election of officers for the ensuing year resulted as follows:

Dr. F. C. Shattuck, of Boston, Chairman; Dr. G. A. Fackler, of Cincinnati, Secretary.

The topic for discussion at this session was the

DIAGNOSIS AND TREATMENT OF DISEASE OF THE STOMACH.

Dr. William Pepper, of Philadelphia, opened the discussion with some practical remarks on the diagnosis of diseases of the stomach. To illustrate his points he cited a number of cases:

Case I.—A man had been losing two pounds in weight per week for a period of sixteen weeks. No disease could be detected. Blood and urine normal. No affection of heart and lungs. No enlargement of the spleen or glands. Inspection of the fundus of the eye presented no data of significance. No pain, vomiting, or constipation. Teeth had failed and hence mastication was imperfect. Careful diet, with small doses of arsenic, brought about a temporary improvement, but emaciation in time resumed its progress. Only by a process of exclusion did the speaker arrive at a diagnosis of developing cancer in the walls of the stomach. The case resulted fatally three or four months after it was first observed by the speaker, and the walls of the stomach were found to be the seat of general carcinomatous infiltration. Such cases demonstrate the want of something necessary to render a diagnosis accurate. Not only in rare cases like this, but in many others, only one or two symptoms of any importance may be present, and these will not be clear enough to warrant a definite diagnosis.

The speaker had but recently seen a business man, sixty-four years of age, who had previously enjoyed good health, but was suddenly attacked with severe pain in the pit of the stomach, coming on when the organ was empty. It recurred every night, and extended from the pit of the stomach to the back. The bowels were rather inactive. He had lost thirty to forty pounds, and was pale but not cachectic looking.

Most careful search of the epigastrium revealed nothing. The radial arteries were hard; arcus senilis was present; the abdominal aorta pulsated strongly and appeared somewhat enlarged. No evidence of pancreatic disease. Under the institution of a careful diet, the administration of hydrocyanic acid, and the application of the thermo-cautery to the region over the stomach and back, a most remarkable improvement was noted. But it was only transient. Months passed and emaciation advanced, and a hardness could be detected close up to the crura of the diaphragm. Patient died, and an autopsy revealed a fungous epithelioma in the superior and posterior walls of the stomach, doubtless involving nervous filaments in the dense adhesions.

The speaker desired to call attention to the application of organic chemistry in the examination of the contents of the stomach. Vomiting occurs so frequently, and the vomited matter is so mixed with portions of the previous meals or with mucus, etc., that it is necessary to remove the contents of the stomach by aspiration. It should be done at a definite time after the ingestion of a definite meal, consisting of a certain amount of mixed starchy and nitrogeneous food. The matter so obtained should be tested for free hydrochloric acid, lactic acid, and peptic strength, that is, the power it possesses to still further digest albumen. The methyl violet is the best test for hydrochloric acid. It is asserted by Riegel, on evidence furnished by thousands of investigations, that, when cancer is present, no free hydrochloric acid will be found in the contents of the stomach six hours after a test-meal. Here, then, we have a point of enormous importance if it be established.

The secretion of the stomach is just as easily obtained as urine. Here, then, a field has been opened that appears to promise large results. These new diagnostic methods may be accepted as possessing confirmed value, although not regarded as infallible.

Dr. F. C. Shattuck, of Boston, said that these modern methods of diagnosis are very promising, but that, for the present, our position must be a waiting one. The

HYDROCHLORIC-ACID TEST

is not an infallible one, for free hydrochloric acid has been found in undoubted cases of cancer, and has been absent in atrophy of the gastric tubules, in chronic gastric catarrh, and even in an apparently normal state. Another question to be considered is the quantity of the acid present. While the test for the acid is satisfactory and easy of application, yet, unfortunately, we possess no test which can be put to much clinical use to determine the amount.

We know that in cases of

GASTRIC ULCER

there is a condition of undue gastric acidity. A method has been suggested by Ewald to gain some light as to the proper performance of digestion. He has taken advantage of the new remedy, salol, which is a combination of carbolic acid and salicylic acid, and is not broken up into these constituent parts in acid vehicles. It passes, hence, through the stomach as a whole, but when it comes in contact with the alkaline secretions in the duodenum it is broken up into carbolic acid and salicylic acid, the latter of which, or its salts, are absorbed and may be detected in the urine. This experiment is of value especially in cases of supposed gastric dilatation. Ewald's investigations led him to think that salicylic acid can be detected in the urine one hour after the time of its administration. The speaker had administered the remedy in 50 cases, in 27 of which the reaction was obtained in one hour, or less; in 13, in one to one and a half hour; and in 10, in one and a half to three hours. These were cases in which the stomach was in normal condition. He had also given salol in a few cases of gastric disease. In two cases of chronic catarrh the reaction was obtained in one hour. In one case, two hours to three hours and twenty minutes; in a case of gastric irritation, one and a half hour; case of cancer, one and a half hour; and in a second case of cancer, in two and a half hours. The speaker also referred to the cases of gastric dilatation, or suspected dilatation, in the examination of which auscultatory percussion yields the best results.

Dr. Octerlony had for several years made use of chemical analysis in the diagnosis of gastric disease. In no single case did the examination fail to corroborate the diagnosis. In malignant disease free hydrochloric acid was always absent. The speaker referred to some symptoms which are commonly present in malignant disease of the stomach. Hemorrhage is of frequent occurrence, reversion of appetite is an early symptom, and a temperature habitually lower than normal is noticed at a comparatively early period.

Dr. J. Whittaker confined his remarks to the consideration of the presence or absence of free hydrochloric acid. The general practitioner is not content with a method that demands execution by a chemist, but there can be no such objection here, for the test is easy of execution. A piece of congo paper dipped into a solution of gastric juice is turned blue by free hydrochloric acid. This is a very sensitive test. Should there be any doubt, then the methyl-violet test may be applied. These are easily obtained. It is rarely necessary to employ the pump. The contents should be obtained several hours after the ingestion of a meal. Lactic acid is sought for by means of the carbolate of iron test.

DOES THE ABSENCE OF FREE HYDROCHLORIC ACID INDICATE CANCER?

On this point all seem unanimous that the persistent absence of hydrochloric acid, day after day, is an indication of the presence of cancer. The speaker did not mean to assert that this was infallibly true, but it was just as certainly an indication of cancer as the persistent presence of albumin was of Bright's disease. Hyperacidity indicates ulcer. It is no more necessary to send the material to the chemist than to send urine for the detection of sugar or albumin. The intensity with which congo paper is colored points to the degree of acidity. An interesting point in this connection is that hyperacidity may cause ulcer, and also be the factor which prevents the healing of the ulcer.

Dr. E. Cutter, of New York, then read a paper, entitled

FOOD IN NERVOUS AFFECTIONS.

Thursday, May 10th—Third Day.

Dr. W. C. Wile, of Danbury, Conn., read a paper entitled

SIRUP OF HYDRIODIC ACID IN GENERAL PRACTICE.

The form of remedy employed is the unalterable sirup presented to the profession in 1878. It has been the author's favorite remedy in all asthmatic troubles, and was never exhibited without unmistakable evidences of relief. Excellent results have been obtained in chronic bronchitis of long standing, chronic lead-poisoning, scrofulous diseases, obesity, and in all the latest stages and manifestations of syphilis.

Dr. J. McFadden Gaston, of Atlanta, read a paper on

CEREBRO-SPINAL MENINGITIS.

His object in preparing the paper has been to emphasize the great importance of recognizing the gravity of the situation at an early period, by means of the general symptoms indicative of congestion, and not waiting for indication of inflammation to determine upon the nature of the disease.

As to treatment, the speaker thought that while the recourse to opiates has, in some cases, seemed to afford relief, it is evident that in most cases it only soothed the passage to the grave. There is an urgent demand for restoring the functions of the vital organs, and arousing the nerve-centres to action by revulsive applications externally and revolutionary measures internally.

Relying upon the special properties of calomel and quinine, he has employed them for the purpose of jugulating the progressive development of the congestive stage of this disease. Hot mustard baths were applied to the lower extremities, and cold to the head.

Mustard plasters may also be placed along the spine, as an aid in restoring the energy of the nervous system, and mustard applications may be made to the inner portion of the arms and legs for the same purpose.

The speaker cited cases in illustration and proof of the efficacy of this treatment, followed by the administration of salicylate of sodium and fluid extract of jaborandi.

Dr. Didama, of Syracuse, gave in detail five very obstinate cases of

HÆMATURIA,

which, after resisting ordinary and extraordinary treatment for periods of from six weeks to three months, finally yielded in the course of a week or so to large doses of alum—twenty grains three times daily—or smaller quantities every three hours. He called attention to the importance of having the alum dissolved in a large quantity of water, and claimed that, when so diluted—twenty grains to a goblet of water—it found ready access to the blood and urinary passages, and never produced constipation.

Some of his cases had, under the care of the most eminent physicians, received the best known treatment without the slightest benefit. Alum had been used in some instances, but never in the large doses which he had employed with invariable success up to the present.

Dr. N. S. Davis had met with cases of persistent hæmaturia, so severe as to greatly impoverish the patient and endanger life. He reported a case which could not otherwise be explained than upon the theory that there existed a defect in the influence of the vaso-motor nerves over the vessels of the kidney. Acting upon this theory, the speaker had found the only remedies of value to be ergotin in moderately full doses and the fluid extract of hamamelis. It was probable, he said, that alum well diluted, so as not to create gastric disturbance, would pass through the kidneys in sufficient quantity to increase the tonicity of the kidney vessels.

Dr. G. W. McCaskey thought that the majority of cases of persistent hæmaturia were due to an effusion of blood from the parenchyma of the kidneys, or else to local lesions of the urethra, bladder, ureters, or pelvis of the kidney. He thought that Dr. Davis' view was probably the correct one in many cases.

Dr. H. Gradle, of Chicago, read a paper entitled

HEADACHES FROM OVERLOOKED CAUSES IN THE NASO-PHARYNX AND EARS.

Dr. John V. Shoemaker, of Philadelphia, read a paper on

NAPHTHOL,

in which he spoke in favor of beta naphthol, maintaining that it was of value, and that it was undeserving of all the hard words that had been spoken against it.

Dr. V. C. Vaughan, of Ann Arbor, Mich., presented a communication entitled

THE ETIOLOGY OF TYPHOID FEVER,

presenting in detail his experiments with the Eberth bacillus obtained from drinking-water, and the successful inoculation of dogs with the germ.

Dr. John North, of Keokuk, Ia., read a paper upon the part taken by the

SYMPATHETIC NERVOUS SYSTEM IN DISEASE.

The Session was then adjourned.

The Number of Births in Paris in a week averages 1,065, of which 779 are legitimate, and 286 illegitimate.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, April 17, 1888.

SECTION ON PRACTICE OF MEDICINE.

R. C. M. Page, M.D., Chairman.

Dr. G. R. Elliott read a paper (see p. 579) entitled

SOME INTERESTING CLINICAL PHENOMENA OBSERVED IN A CASE OF CIRRHOSIS OF THE LIVER.

Dr. Page asked whether there was a malarial element in the case, or whether the cirrhotic condition of the liver alone would account for the enlargement of the spleen.

Dr. Elliott replied that there was no history of malaria, and quinine was administered without effect. He thought the enlargement of the spleen might be accounted for in part, at least, by the condition of the liver and the interference with the return circulation.

Dr. A. F. Currier thought it important to determine in what cases strophanthus might be contra-indicated. He had, the past few days, used it in a case of supposed fatty heart, the patient being one on whom he had performed Alexander's operation and posterior colporrhaphy. The previous night, while still under the influence of strophanthus, the patient went into profound collapse and was with difficulty revived. The drug had proven so ineffective in this case, both as to its immediate effect upon the heart and its influence upon the arterial tension in general, that he felt sceptical as to its value in fatty degeneration of the heart. The patient was again put upon digitalis, which had previously been employed, and the signs of convalescence again returned.

It was claimed that strophanthus was purely a heart-stimulant, its action being, he supposed, upon the muscular fibre of the heart, and the question had arisen in his mind, why should it not have had more effect in this case?

Dr. Leonard Weber, speaking of the value of strophanthus in general, said he had found Frazer's tincture, used in doses of ten to fifteen drops three or four times a day, an efficacious remedy where a cardiac tonic was indicated. But it was not as uniformly efficacious as was digitalis. He would have expected the result experienced by Dr. Currier, that strophanthus would fail in fatty degeneration of the heart, while digitalis would prove useful as long as a majority of the muscular fibres were capable of responding to its influence. He could testify to what the reader of the paper had stated, that strophanthus had a decided effect upon the heart-muscle without increasing the arterial tension, so far as could be determined by feeling the radial and temporal arteries. He had satisfied himself of this action of the drug in a case of cardiac dilatation resulting from primary cirrhosis of the liver, in which strophanthus proved beneficial while digitalis failed. He had had no experience with it in dropsy due to cirrhosis of the liver. He would mention incidentally, however, two cases in which calomel had proven of much benefit by its diuretic effect. It was well known that the diuretic effect of calomel was most marked in heart disease, particularly that of the mitral variety. It should not be forgotten that in some cases of dropsy diuresis could not be induced until mechanical obstruction had been overcome by tapping.

Dr. George R. Lockwood then read a paper (see p. 576) on

IMPACTED RENAL CALCULUS, WITH REPORT OF A CASE.

Dr. Weber thought the reader of the paper had expressed the belief that neither in his case nor in others could suppression of urine have been due to complete occlusion of one ureter, while the other kidney and ureter remained normal. In opposition to that view, he cited his own case as an example among others in which renal colic had caused suppression of urine for as long as six hours, although neither kidney, so far as could be determined, was the seat of organic disease. The passage of the calculus was followed by an abundant flow of urine, and diuresis for some hours afterward. All must have observed functional suppression of urine in urethral fever following internal urethrotomy, etc. He had seen complete anuria in two cases of scarlet fever in children, which continued five days, yet the patients recovered. Dr. Weber conceived that a calculus completely occluding a ureter, for a period of not two or three hours but of from six to twenty-four hours, might lead to such relaxation of the tissues and such functional disturbance as to allow in that length of time of a certain amount of hydronephrosis. If such cases were spoken of as acute hydronephrosis, of course it would not be expected that the tumor would have attained to the immense size often seen in chronic hydronephrosis. Nor would he suggest that the amount of hydronephrosis in such a case would explain the abundant flow of urine which took place after the passage of the calculus. That and the subsequent diuresis might well be accounted for by the influence upon the blood-vessels as suggested by the author. He asked whether morphine had been administered?

Dr. Lockwood said only half a teaspoonful of paregoric had been administered by the mouth every two or three hours during one period of the attack.

Dr. F. W. Jackson asked Dr. Lockwood whether it was not possible that the diuresis was due to a nervous element such as physicians were accustomed to see in hysterical polyuria.

Dr. Lockwood said the man was not in the least hysterical, and he thought it was unnecessary to fall back on some obscure nervous trouble in explaining the polyuria.

Dr. Page, speaking with reference to hydronephrosis, mentioned the case of a woman whom he first saw six or seven years ago, who had a large tumor in the left lumbar region, determined to contain urine, and which disappeared from time to time on the passage of a large quantity from the bladder. He was unable to trace the hydronephrosis to obstruction of the ureter from a calculus in the first instance.

The discussion then turning upon the general treatment of calculus,

Dr. Weber spoke of the value of the waters of Poland Springs, Me., and of the Cabot Springs, W. Va., expressing the belief, based on personal experience and that of friends and patients, that they were not inferior to those of Vichy or Carlsbad or other alkaline waters. He further expressed the belief that the value of such waters was not due alone to washing out of the system, as simple water taken in large quantity did not have the same beneficial influence. Mineral waters artificially prepared, however, might be equally efficacious.

Dr. Page had made quite a study of the Carlsbad waters in 1885 and 1886, and while there had learned that eminent physicians in Germany did not claim that they possessed solvent power over calculi which had formed in the system, but that they washed the uric acid out of the tissues and thus prevented the formation of large calculi. It was claimed that the Buffalo lithia water in Virginia was a solvent of uric acid, and it had acquired much reputation in Germany as possessing such power.

Dr. A. Jacobi remarked that there was a greater affinity between uric acid and potassium salts than between uric acid and sodium salts. He had found by experience that this was not only chemically true, but that potassium salts were superior to sodium salts when taken internally against gravel. One drachm of bicarbonate of potassium might be taken daily for an indefinite length of time without causing gastric disturbance or affecting the general health. The drachm should be dissolved in a quart of water and be drunk during the day. It cost but a trifle. It might be dissolved in one of the sparkling waters if preferred. Dr. Jacobi remarked that washing out would not be sufficient if a stone were lodged somewhere; the alkaline water should reduce it, permitting of its passage outward, and should prevent the further formation of stone.

Dr. Devlin said that about two years ago an account was published in the *British Medical Journal* of experiments which went to show that salicylic acid and its salts acted in a way to break up the nitrogeneous secreta and reduce the amount of uric-acid deposit. He was in the habit of giving small doses of salicylate of sodium in cases in which there was much deposit in the urine.

Dr. Lockwood, in closing the discussion, said he had admitted in the paper it was quite rational to suppose that pain arising from a calculus lodged in one ureter might for a time cause suppression of urine by its reflex action. But he did not think the anuria due to such reflex action would continue as long as in the cases reported, viz., from one to twenty-three days. Regarding whether sudden and complete obstruction of the ureter would cause hydronephrosis, he had argued only from experiments and the findings at autopsies. Hydronephrosis had been found only in cases of long standing; in none was it acute.

Buffalo lithia and other alkaline waters had been given in his case with negative effects; when Farmville lithia was administered the uric acid in the urine was enormously increased in quantity. It seemed possible it resulted from dissolution of the uric-acid calculus in the kidney.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE SUMMER SESSION—RECENT MEETINGS OF THE SOCIETIES—INCISION VS. EXCISION OF JOINTS—PERI-HEPATITIS—OVARIAN TUMOR WITH PRECOCIOUS PUBERTY—PRIMARY CANCER OF FALLOPIAN TUBE—CASE OF MULTIPLE CANCER—CANCER OF THE BRAIN—THE PARKES MUSEUM OF HYGIENE—THE ROYAL COMMISSION ON UNIVERSITY EDUCATION IN LONDON.

London, May 7, 1888.

The summer session of the medical schools began nominally on Tuesday last. Practically, real work will begin with this week. The commencement of work at the medical schools is singularly synchronous with the advent of warmer weather, to-day being almost the first real warm day we have had. We are not usually troubled with excessive heat, in this country, even in the summer, though I have heard a medical student exclaim, as a reason for not working in the summer session, that it was "too hot!" Such an excuse would not be of much use now, for the increased stringency of almost all the examinations has rendered it necessary for students to work as hard in the summer as in the winter. Several of the most important examinations, also, are held within the next three months. When it gets to the middle of July, however, the benches will begin to thin, and both teachers and students will be looking forward with eagerness to the vacation. At one of the metropolitan schools, so difficult is it to get a class in July that it has for several years become the custom to bring the summer courses of lectures to a close during the second week of that month. The medical societies will cease to meet at a much earlier date. Some, in fact, have already closed for the session.

An interesting case was described by Mr. Wainewright at the last meeting of the Clinical Society. The patient was a boy, three years of age, who was admitted into the West London Hospital with a large superficial abscess on the outer aspect of the left thigh. This was said to have resulted from a fall. It was opened and drained, but, a fortnight later (before the incision had healed), the right hip became inflamed. At the end of another month, distinct fluctuation being detected in four of his joints, the right hip-joint was opened, a quantity of pus evacuated, and some carious bone removed by scraping from the anterior part of the neck of the femur. The wound was dressed antiseptically, and healed in a month, leaving a movable joint. The left knee then became tender and painful; it was freely incised and the cartilaginous surfaces freed from an overgrowth of synovial membrane by means of a sharp spoon and scissors. Antiseptic dressings and drainage were employed, and the child left the hospital six weeks later with a plaster splint on the knee, the wound having healed. Seven months afterward he was readmitted, and a small exfoliation of bone was removed from a granulation-cavity just above the left knee. The sinus healed, but the knee became partially flexed, from the splint having been removed by the parents against orders. An effort had been made to correct this by extension and another plaster splint, but considerable deformity still existed. The knee was nearly immovable, but the movements of the right hip were perfect. Some discussion followed the reading of the case. Mr. Bennett questioned whether the condition of the joint was better than would have followed excision. Mr. Lucas thought that so far as the hip was concerned he would agree with what Mr. Wainewright had advocated; viz., incision, examination, and removal of any carious bone in the neighborhood. He remarked that, as at present practised, excision was a very different operation from what it used to be. He always clipped away the synovial membrane all round before proceeding to remove the bone. Mr. Howard Marsh thought the question was whether the disease of the joint was tubercular or pyæmic. He had often seen good results follow Mr. Wainewright's treatment in pyæmic abscesses, but doubted whether this would be the case in tubercular disease. He had himself been much disappointed with the results obtained from excision of the hip, and thought excision was destined to become more rare. Mr. Symonds said his own experience was in favor of the method adopted by Mr. Wainewright, but there were a number of cases in which excision was the only operation.

At the same meeting of the Society, Dr. Hale White read a paper on peri-hepatitis in which he expressed the opinion that universal peri-hepatitis was, in the great majority of cases, part of a general disease consisting of chronic peritonitis and universal capsulitis of spleen and liver, and that it was almost invariably associated with granular kidneys, and frequently with gout, syphilis, alcoholic excess, or diseases of the heart or lungs causing backward pressure. Mr. Lucas read a paper on a case of malignant tumor of the ovary in a child of seven, associated with precocious puberty. Ovariotomy was performed, and the tumor proved to be a round-celled sarcoma. The child made a good recovery, and when seen, two years and nine months after the operation, was in good health.

At the Pathological Society Mr. Alban Doran exhibited a specimen of cancer of the Fallopian tube which he believed to be an example of primary cancer. The tumor-substance was made up of collections of large polymorphous cells, surrounded by trabeculæ which were infiltrated with small cells. Only three cases of primary malignant disease of the tube had been placed on record, viz.: (1) A doubtful one by Scanzoni; (2) a case of sarcoma by Dr. Senger, of Breslau; and (3) a case of Dr. Martins, described by Dr. Orthmann as an instance of true cancerous papilloma. Dr. Joseph Coats showed a specimen of multiple cancer of various organs. There was an old cavity with cancerous walls in the right lung, which he regarded as a primary ulcerating cancer of the lung. There were secondary tumors in the bones, liver, pancreas, and kidneys. In the brain, there were twenty-four cysts of various sizes, ranging from one-fourth of an inch to two inches in diameter; the cysts had a definite lining of epithelium. The bones were also affected, the expanded ends of the femur being largely occupied by cysts in various stages of development, from simple collections of epithelium to large spaces filled with colloid material. Dr. Coats also exhibited a specimen of primary cancer of the brain. The tumor was oval, and measured an inch and a half in diameter. It was situated above the pons and peduncles, apparently growing in the aqueduct of Sylvius, distending it and projecting into the fourth ventricle. The anterior part of the aqueduct was unaffected, and the third ventricle normal. Microscopic examination showed the principal constituents to be cylindrical epithelium cells arranged in rows and enclosing spaces. Dr. Coats suggested that the tumor originated from the epithelium of the aqueduct. The patient had been under Professor Gairdner, and the clinical history of the patient was that she had suffered from "weak turns," pain in the head, vomiting, and retraction of the head. She gradually became very lethargic and difficult to rouse, and became more and more emaciated, until death.

The Parkes Museum of Hygiene has not yet been able to attain a satisfactory financial position, in spite of its added strength due to amalgamation with the Sanitary Institute. It is now proposed to unite with it several other institutions; viz., the National Health Society, the School of Cookery, and the Smoke Abatement Society. It is hoped thereby to form an establishment for the practical teaching of hygiene in all its branches. At a meeting held at the Parkes Museum on Saturday last, at which the Duchess of Albany presided, Sir Douglas Galton said that if those institutions would combine there was reason to believe that ample funds for the endowment of a great national college of hygiene would be forthcoming.

The constitution of the forthcoming Royal Commission on University Education in London has been now definitely settled. Lord Selborne, a former Lord Chancellor, is to be the chairman, and all the members of the commission may fairly be regarded both as men of eminence and representative of varied interests. It is, however, a disappointment to find that no medical man is to sit on the commission.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE ETIOLOGY OF GOUT—RESULTS OF OPERATIONS FOR CATARACT.

Paris, May 4, 1888.

Various views prevail concerning the etiology of gout. Most English and American authors attribute it to troubles, more or less pronounced, of the liver or of the stomach, or of both organs a tthe same time—troubles which almost always precede an attack of gout.

At a recent meeting of the Société de Biologie, Dr. Leven endeavored to show that gout is not a malady in itself, that it is caused by a trouble of the nervous centres. The author explained that in health the blood, which is an alkaline liquid, eliminates in twenty-four hours forty or fifty centigrammes of uric acid. When an attack of gout is about to occur, the blood loses its alkalinity, owing to the presence of organic acids—lactic acid, oxalic acid, etc., and particularly in consequence of the presence of the urates of soda which accumulate in it. The blood, surcharged with uratic salts, gets rid of them either by depositing them in the kidneys or in the articulations, and in that of the great toe in preference, or in the tissues. The blood, when rid of its urates, recuperates its alkalinity until, by some excess of the table, the urates reappear in excess, to prepare a fresh attack of gout. It is by this chemical fact, which characterizes an attack of gout, that clinicians endeavor to explain the innumerable maladies with which a gouty subject is affected in the course of his existence. Uricæmia is made responsible for headaches, giddiness, asthma, angina pectoris, dyspepsia, enteralgia; but Dr. Leven considers that the excess of urates is only an accidental transitory circumstance, whereas the diseases named are the results of neurosis, which succeed and evolve long before the appearance of the uricæmia. Thus a child who would become gouty only at the age of twenty or thirty years, suffers for a long time before from headache, giddiness, etc.; that is, long before the first attack of gout. It is under the influence of neurosis that the nutrition is troubled, and that the urates accumulate at certain periods. The neurosis begins either in the brain, the solar plexus, or in the spinal marrow, or in the nerves which emanate from one of the centres. It is for this reason that the individual is affected with headache, giddiness, etc. The author therefore concludes that gout should not be considered as a malady, but as a neurosis; and that it would disappear when the nervous centres are re-established; consequently the treatment of gout should have in view particularly the treatment of the nervous system.

In this connection it may be interesting to place before your readers an extract from a work recently published by Dr. Robson Roose, on gout and its relations to the diseases of the liver and of the kidneys. This author insists particularly on the derangements of the liver or of the stomach which almost always precede an attack of gout, as having a very great importance in the etiology of the malady. He refuses to admit the neuropathic origin of gout. "I would not ask for better," he said, "than to admit that, behind a good number of symptoms, there is a trouble of the nervous system; but these latter are due to the toxic action on the nervous centres of excrementitious materials engendered in the blood by imperfect metabolic transformations. The varied neuroses which often torment gouty subjects are probably dependent on an analogous cause. In any case, the hypothesis of antecedent nervous lesions has no demonstrative fact." Uric acid under the form of urate of soda constitutes the materies morbi of gout, its production in excess is the result of a transformation of albuminoid substances, and the cause of this imperfection is for a great part due to the functional trouble of the hepatic gland. As to the kidneys, they are implicated in the lesions only in a secondary manner, although the distinct attacks of gout may be subdued as long as the renal function is adequate to the work of the elimination of this uric acid in excess. According to this theory, the therapeutic indication would be the neutralization of the materies morbi by the aid of alkalies, and particularly by the restoration in their integrity of the functions of the liver.

Dr. Landolt, the well-known ophthalmologist, lately made an interesting communication to the Academy of Medicine, proposing certain reforms in the treatment of strabismus. The author looks upon, as one of the predisposing causes of strabismus, a defect of harmony in the development of the different parts of the visual organ. He includes also, in the etiology of strabismus, contractures and hysterical paralysis of the ocular muscles, a cause that is frequent but scarcely known, and which necessarily demands a particular treatment. As regards the diagnosis, Dr. Landolt exacts a good deal of precision in the measure of the degree of strabismus, of the movements of the eyes, and of their function, whether isolated or simultaneous. But the principal reforms which he proposes bear on the therapeutics of strabismus. The treatment, based on complete and exact observations, should consist in the combination of all the means appropriate to diminish the tendency to strabismus, to fortify the muscles, and, above all, to develop the binocular vision. By these means the number of operations will be reduced, and if surgical intervention be necessary, it will be less extensive, more efficacious, more durable, and more complete. Although the operative procedures have been improved, Dr. Landolt has recourse to them only after having reduced the strabismus, as much as possible, by methods to which he has given the name of orthoptics. He continues these even after the necessary operations, as a sort of finish, not only in an æsthetic point of view, but principally as regards the function of the eyes. Without binocular vision, says the author, we give the patient only an apparent cure; if, on the contrary, we succeed in rendering to him the harmonious function of his two eyes, he will have, besides the considerable advantages of this faculty, that of being guaranteed against a return of the strabismus.

In a paper giving the results of operations for cataract, performed by Professor Panas, he stated that, of 480 cases during the last three years, success was complete in 427. The learned professor attributes these happy results to the antiseptic "lavage" (washing out) of the anterior chamber. Formerly, he employed for this purpose a solution of the biniodide of mercury; he now prefers a saturated solution of boric acid of three or four per cent. In concluding his paper, M. Panas remarked that "antisepsis, properly practised, had not only rendered the optical success constant, but it permitted a complete return to the operative ideal, to the method altogether French of our immortal David."

THE DIAGNOSIS OF VESICAL TUMOR BY THE CYSTOSCOPE.

To the Editor of The Medical Record.

Sir: In The Medical Record of May 5th last, Dr. Fessenden N. Otis reports a case of diagnosis of tumor of the male bladder by the use of Leiter's cystoscope, and considers it especially interesting as being the first case of tumor thus diagnosed and verified by subsequent operation in America. Undoubtedly Dr. Otis did not happen to see an article of mine published in the *Boston Medical and Surgical Journal* of December 1, 1887, on "The Endoscopic Instruments of Joseph Leiter, of Vienna, and the Present Development of Endoscopy." He will there find that I have twice diagnosed a tumor of the bladder with the cystoscope of Leiter. I did not then go into the details of the cases, as they were seen in consultation and are to be published later. The first case was diagnosed on October 23, 1887, and operated upon four days later by Dr. M. H. Richardson, at the Massachusetts General Hospital. The second case was seen on the 10th of the following December, at the same hospital, in consultation with Dr C. B. Porter. It was a recurrent villous tumor, the original growth of which Dr. Porter removed by suprapubic cystotomy, September 29, 1886. The microscopic examination by Dr. W. W. Gannett, at that time, showed the tumor to be a papillary growth from the mucous membrane of the bladder, composed of delicate loops of vessels covered by a many-layered epithelium. The patient, who is kept under observation, was seen last Thursday, May 17th, and still has no symptoms which incline him to another operation. Dr. Richardson's case, in which the tumor was also removed by suprapubic cystotomy, will soon be reported in full in the *Boston Medical and Surgical Journal*.

Very truly yours,

Otis K. Newell.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 19, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	5	4
Scarlet fever	175	29
Cerebro-spinal meningitis	7	6
Measles	191	8
Diphtheria	211	63
Small-pox	19	5
Yellow fever	0	0
Cholera	0	0

The Solubility of Benzoic Acid.—Dr. G. W. Tinkham, of Weymouth, writes that he prescribed a mixture of benzoic acid, ʒ ij.; borax, ʒ iij.; in water, ℥ xij., as recommended by Dr. Chunn, for irritable bladder, but was informed by his druggist that the benzoic acid would not dissolve in that quantity of water. Benzoic acid is soluble in 500 parts of cold water, and in 15 parts of boiling water, but its solubility is largely increased by the addition of one and a half part of borax.

The Medical Record

A Weekly Journal of Medicine and Surgery

Vol. 33, No. 22 New York, June 2, 1888 Whole No. 917

Original Articles.

SULFONAL, A NEW HYPNOTIC.

By EDMUND CHARLES WENDT, M.D.,

VISITING PHYSICIAN ST. JOSEPH'S ASYLUM; CURATOR AND PATHOLOGIST OF THE ST. FRANCIS HOSPITAL, AND OF THE NEW YORK INFANT ASYLUM, ETC.

Among the class of so-called "troublesome" affections, insomnia is entitled to a foremost place. If medical statistics are to be trusted, idiopathic sleeplessness is certainly on the increase all the world over. And perhaps this is true to a larger extent in our own country than anywhere else. So long as the pathology of the condition in question, if it has a pathology, is so little understood, we must be content to deal with it in an empirical way. For neither the assumption of cerebral anæmia, nor of cerebral plethora, nor of any other single morbid state, will suffice to explain many of those cases that prove alike troublesome to the practitioner, to the patient, and to his family.

These facts have for some time been so clearly understood, that earnest and persevering researches have been undertaken, with the view of finding some remedy that would meet the symptomatic indications of the disorder, without possessing, at the same time, properties that involved actual or potential danger. It is, unfortunately, only too true that our best-known narcotics are potent for mischief in both directions. Baneful habits are encouraged by their unstinted employment, and in more moderate dosage they fail to afford the desired relief.

Thus it has happened that, within the past few years a number of new remedies have been introduced, the action of which, we have been told, was unlike opium, chloral, cannabis, or the bromides. Most of these drugs belong to the acetal group of compounds. They include methylal, acetophenon (better known as hypnon), urethan, paraldehyd, and hydrate of amylen. The two last named have found some favor at the hands of the profession, although none of the remedies named have proved uniformly satisfactory.

The most recent drug of this kind comes to us with the endorsement of eminent German authority. But it comes to us unheralded by the usual exaggerated accounts of hitherto unheard-of efficacy and universal applicability. According to Professor Kast,[1] of Freiburg, sulfonal is a hypnotic pure and simple. It does not compel sleep through a paralytic effect on the nerve-centres, nor through a profound impression produced upon the vascular system. From numerous experiments on animals, and many clinical observations on man, the action of this new remedy would appear to consist merely in the intensification of those factors that lead to natural sleep in the physiological sense, or in supplying the periodical desire for sleep in those cases where it is wanting. It is for this reason, probably, that the range of applicability of sulfonal is a more limited one than that of some other drugs employed as hypnotics.

But sulfonal, we are informed, has none of the disadvantages inherent in the deadly narcotics, and it is much more reliable than any of the bromides. This new body does not disturb digestion, it is not constipating, it has no unpleasant after-effects, it is perfectly harmless, it does not invite the formation of "a habit," and, finally, it does not appear to lose its efficacy, even when employed for a long period. Surely this is enough to recommend sulfonal to our attention, and if the profession will confirm the claims put forth by its sponsors, there can be no doubt that an extremely valuable addition will have been made to our stock of remedies.

Sulfonal was first prepared by Baumann,[1] formerly assistant to Hoppe-Seyler, and well known for his numerous researches concerning organic compounds. It would appear that, like so many of our newer drugs, this body was found only partly in consequence of a definitely understood purpose, and in part as the result of accident.

Professors Kast and Baumann had been engaged in investigating a series of bodies known as disulfones. Almost the first substance submitted to a more detailed analysis and examination was the product of oxidation of a compound, resulting from the action of acetone or æthylmercaptan. It was this body that later was found to be the valuable hypnotic under consideration.

Chemically this substance enjoys the euphonious designation of "diæthylsulfondimethylmethan." We fully concur in the opinion expressed by Professor Kast, that "sulfonal" is a more comfortable name. The formula of the new drug is $(CH_3)_2 = C = (SO_2C_2H_5)_2$. It occurs in the form of large flat, colorless crystals, which are tasteless and devoid of smell. Sulfonal is soluble in 18 to 20 parts of boiling water. In tepid water the solubility is only about one to one hundred. The crystals dissolve more readily in alcohol and alcohol mixed with ether. Acids and alkalies do not affect the composition of the body, which appears to possess considerable chemical stability. The crystals melt at a temperature of 257° to 260° F.

As regards dosage, we learn that fifteen to sixty grains usually suffice to insure several hours of refreshing sleep. The hypnotic effect is observed from half an hour to two hours after the exhibition of the drug. It is best administered mixed with a little water, or in wafers or capsules. An average dose to begin with is fifteen grains.

It appears that sulfonal is specially applicable to the simple insomnia so often witnessed in neurotics. But it has also been found useful in febrile wakefulness, in the restlessness of organic heart disease, and even in the delirium of dementia.

Sulfonal has already been largely employed in the treatment of mental disorders. Dr. Rabbas,[2] of the Marburg Lunatic Asylum, has published a special report in which he speaks very highly of this new remedy. He has used it over two hundred times, with uniformly gratifying results. He emphasizes particularly its absolute harmlessness, which contrasts favorably with the greater or less danger of the hypnotics hitherto usually employed in lunacy practice.

The best time to administer sulfonal would appear to be the late afternoon and evening hours. From five to eight, or even ten, hours of profound sleep usually follow its use. Women are more readily influenced by the drug than men, and fifteen grains is generally sufficient to put them to sleep.

Professor Kast believes that sulfonal affects the gray matter of the brain, but in what way he does not state. From carefully conducted microscopical and spectroscopical examinations, it is asserted that this substance has no ill effect on the blood. This holds good even in the case of animals actually poisoned by its use. The mucous membrane of the alimentary canal likewise remains unaffected by its internal administration.

[1] Sulfonal, ein neues Schlafmittel. Von Prof. A. Kast, in Freiburg i. B. Separat Abdruck aus Berliner Klin. Woch., No. 16, 1888.

[1] Ber. der deutschen Chem. Gesel., vol. xix.

[2] Ueber die Wirkung des Sulfonals, von Dr. J. Rabbas. Separat Abdruck aus Berlin. klin. Woch., No. 17, 1888.

I have not hitherto been able to obtain the drug in this city, and I have, consequently, no personal experience concerning its efficacy.

Through the kindness of my friend Dr. Kammerer, of New York, I am able to state that a supply of this drug, sufficient for clinical trials, has already been shipped by Professor Kast to him, and is daily expected by us.[1]

I have not hesitated to give to the readers of THE MEDICAL RECORD early information regarding sulfonal, because it has the endorsement of gentlemen whose professional standing offers a guarantee of the trustworthiness of their assertions. It goes without saying that we will require the confirmatory evidence of the profession at large, before we can state positively that, in the discovery of sulfonal, we have really found the much-sought-for desideratum, namely, a safe, unfailing, and yet powerful hypnotic.

712 MADISON AVENUE,
May 21. 1888.

ON THE CHEMICAL EXAMINATION OF THE GASTRIC SECRETIONS FOR DIAGNOSTIC AND THERAPEUTIC PURPOSES.[2]

By FRANCIS KINNICUTT, M.D.,

PHYSICIAN TO ST. LUKE'S HOSPITAL AND THE NEW YORK CANCER HOSPITAL.

IN view of the interest shown, at the present time, in investigations of the character of the gastric secretions in various derangements of the stomach, a practical demonstration of the methods most recently employed in these studies, with a statement of some of the conclusions deduced from the latter may be of interest. With a knowledge of the part which hydrochloric acid takes in stomach digestion, any means which will enable us to determine with accuracy its presence or absence in the gastric juice, and with approximate correctness an excess or diminution in its secretion, must be regarded of much practical importance. Various chemical tests have been employed in the examination for free hydrochloric acid and the organic acids in the gastric secretions; the best known qualitative tests for the former are the methyl-violet, the Congo-red, the tropæolin, and, finally, the phloroglucin-vanillin test of Günzberg. A thorough trial of these, extending over a period of two years, has led me to rely wholly, at present, upon the last mentioned, which is of comparatively recent introduction. Its advantages, which do not obtain with the other tests, are that it is not affected by the organic acids or by the chlorides in combination with these acids, and, finally, that its delicacy is not impaired by the presence of peptones. The formula [3] for its preparation and the technique for its application are now comparatively well-known.

The delicacy of the test is sufficient to invariably detect the presence of one-twentieth of one per cent. of free hydrochloric acid. I have repeatedly detected with it the presence of one-fortieth of one per cent. in artificial solutions.

Uffelmann's carbolized chloride-of-iron test for organic acids may be regarded as sufficiently accurate for clinical purposes. The formula for its preparation is as follows: Mix three drops of liquor ferri chloridi (German Pharmacopœia), three drops of a very concentrated solution of carbolic acid, and twenty cubic centimetres of distilled water.[1]

The solution thus prepared has an amethyst-blue color. It becomes yellow, and is finally decolorized in the presence of minute quantities of lactic acid, the organic acid most commonly found in the gastric secretions. The methods employed for the quantitative estimation of hydrochloric and lactic acids will be considered later.

For a number of months a systematic examination of the contents of the stomach in all patients suffering from gastric disorders has been made in my wards in St. Luke's Hospital. Many analyses have been made in the same and different patients, and the results obtained have been instructive in many ways and of assistance in diagnosis and therapeusis. The technique of the examinations is very simple. A test meal, consisting of bouillon, meat, and a small quantity of well-cooked rice, is given, and the contents of the stomach withdrawn, *undiluted*, by means of a stomach-pump, from three to four hours later. They are then filtered, and a few drops of the phloroglucin-vanillin solution added to an equal amount of the filtrate, which is gently heated in a white porcelain dish. The reactions previously described demonstrate the presence or absence of free hydrochloric acid. A test for the organic acids is then employed, and finally a quantitative estimation of the hydrochloric acid, if present, is made. I shall not detain you, this evening, with a detailed report of cases, but wish simply, with a practical demonstration of the methods employed, to point out certain sources of error in these examinations, chiefly learned by personal experience; to state the rules of procedure which I have adopted in consequence, and finally, to refer to such conclusions as seem reasonably justified by the work in this field up to the present time.

As the stomach frequently has been found to be empty five or six hours after the ingestion of food, the time recommended by Riegel for examinations, I have adopted the rule of examining its contents between the third and fourth hours after a meal. Occasionally an absence of hydrochloric acid has been found in an analysis made at this time, and its presence detected in a re-examination at a later period. I am, therefore, in the habit of again employing the stomach-pump as late as the sixth or seventh hour after a meal, if hydrochloric acid has not been found in the earlier analysis. The non-observance of such a rule may possibly explain some of the contradictory statements which have been made in regard to the absence of hydrochloric acid in apparently similar gastric derangements. I have accepted the statements of German observers in regard to the percentage amount of free hydrochloric acid present in normal digestion. As it apparently fluctuates within certain limits, a range between 0.22 and 0.28 per cent. has been regarded by me as normal. The quantitative estimation of hydrochloric acid in the gastric secretions, in the *absence* of organic acids, is a comparatively simple process. The well-known titration method is employed for this purpose.[2] My experience, however, leads me to believe that very frequently organic acids are *present* in the contents of the stomach in many of its derangements. In this case all methods for the quantitative determination of hydrochloric acid *without the previous elimination of the organic acids are quite worthless for correct conclusions.*

From a very careful review of the work of many German observers in this field of investigation, the conclusion has been forced upon me that the presence of organic acids is frequently disregarded by them. The quantitative estimation of hydrochloric acid in such cases necessarily, therefore, is only one of the *absolute* acidity of the gastric contents.

---

[1] The druggists Eimer & Amend have, at my suggestion, also ordered an adequate supply of the drug from the German manufacturers, Fr. Bayer & Co., in Elberfeld.

[2] Read before the Practitioners' Society, May 4, 1888.

[3] One part vanillin, two parts phloroglucin, are dissolved in thirty parts of absolute alcohol; one drop of this solution in the presence of concentrated HCl gives a bright red color, with the formation of cherry red crystals. With the dilute acid a similar reaction occurs only after gently heating the fluid, preferably in a white porcelain dish, when a red zone or streaks appear at the edge of the evaporating fluid.

[1] It is necessary to prepare the test fluid fresh each time before using.

[2] To estimate the amount of hydrochloric acid in a given amount of a solution (for example, 50 c.c.), ascertain how many cubic centimetres of a standard alkaline solution are required to neutralize it. The alkaline solution usually employed is a deci-normal solution of sodium hydrate. Each cubic centimetre of this contains .004 gramme of caustic soda, and will exactly neutralize .00364 gramme of absolute hydrochloric acid. The test alkali is slowly added from a burette, with constant stirring, until a neutral reaction is obtained with litmus or any other suitable indicator. The number of cubic centimetres so used, multiplied by .00364, gives the number of grammes of absolute hydrochloric acid contained in the 50 c.c., from which the percentage can be readily calculated.

The only accurate method for the estimation of the percentage of hydrochloric acid in solution with the organic acids, I am convinced, is that described by Cahn and Meering. The details of their method are as follows:

1. A given quantity (for example 50 c.c.) of the gastric filtrate is carefully distilled in an ordinary distilling apparatus, until it is evaporated down to 10 c.c. By these means the filtrate is freed from the volatile organic acids (viz., acetic, butyric, etc.).

2. The lactic acid [1] is now abstracted from the concentrated residue by agitating it with a large volume of ether and removing the ethereal stratum. Several successive portions must be used to insure that all the lactic acid is taken up.

3. The amount of hydrochloric acid in the sour, watery fluid remaining after the removal of the ether, and therefore in the original portion of gastric filtrate used, can now be ascertained by titration as above described.

I need not call your attention to the fact that a diagnosis of gastric hypersecretion, in contra-distinction to hyperacidity, is only justified by a *demonstration* of the presence of a considerable quantity of fluid, giving the reactions of hydrochloric acid and capable of rapidly digesting albumin, in the stomach quite empty of food. For such an examination the stomach should be thoroughly washed out, preferably in the evening, and the patient should be compelled to fast until the following morning, when the stomach-tube is again introduced. In a patient present this evening such a demonstrable condition exists, associated with dilatation of the stomach. The true position of Riegel and several other observers on the much discussed question of the absence of free hydrochloric acid in cancer of the stomach, it seems to me, is misunderstood. In the absence of hydrochloric acid in the gastric secretion, Riegel by no means finds proof of the existence of cancer, as this condition obtains in several diseases of the stomach. It is in the *constant presence* of free hydrochloric acid that he finds the strongest proof of the absence of cancerous disease. This conclusion is apparently borne out by the great majority of observations up to the present time.

In conclusion, I would earnestly urge the importance of further observations in this comparatively new field of investigation. My own observations, up to the present time, lead me to believe that much assistance is to be gained from such examinations for diagnostic and therapeutic purposes. The determination of the presence or absence of free hydrochloric acid and the organic acids in the gastric secretions is entirely practicable for the practitioner, requiring merely a knowledge of the tests and no more time than is demanded for urinary analyses. Only the quantitative estimation of hydrochloric acid in solution with the organic acids, is possibly impracticable without hospital or laboratory facilities.

The following table embraces the conclusions which seem at present reasonably justified by the chemical examination of the gastric secretions in certain disorders of the stomach:

H Cl, absent or present in minimum amount in the presence of a considerable quantity of bile in the stomach.
H.Cl, absent or present in minimum amount in toxic gastritis.
H.Cl, absent or present in minimum amount in cancer of the stomach.
H.Cl, present in diminished amount in chronic gastritis.
H.Cl, present in excessive amount in ulcer of the stomach.
H.Cl, present in normal amount in nervous dyspepsia (so-called).

I desire to express my indebtedness to Dr. Collins, the house-physician of St. Luke's Hospital, and to Dr. Robert J. Devlin, for their very efficient assistance and co-operation in my investigations.

---

[1] To estimate the amount, if desired, of lactic acid in the ethereal solution, evaporate the combined portions of ether, dilute the residue with a convenient quantity of distilled water, neutralize as in the estimation of HCl, and multiply the number of cubic centimetres of the test alkali used by .009 to determine the number of grammes of absolute lactic acid in the residue.

I. A CASE OF CORTICAL HEMIANOPSIA, WITH AUTOPSY.—II. A CASE OF ARSENICAL PARALYSIS; MULTIPLE NEURITIS.[1]

By L. PUTZEL, M.D.,
NEW YORK.

CASE I.—A. B——, aged fifty-four, merchant, regular habits; while a student drank considerably, but has been a very moderate drinker since graduation; family history unimportant. For a couple of years before death he presented the classical symptoms of chronic diffuse nephritis (abundant urine, of low specific gravity, with a trace of albumin and medium-sized hyaline casts; cardiac hypertrophy and dilatation; uræmic dyspnœa). A year ago the disturbance of the renal and cardiac functions began to approach a climax, and since then they have almost always been performed very poorly. It is an interesting feature, in connection with the Bright's disease, that toward the end of life the daily amount of urea excreted, which was usually much below normal and occasionally would fall to 80 grains, rose on two occasions to 480 grains.

On December 3, 1887, the patient, who was very much constipated, rose during the night and strained very hard at stool, until his eyes seemed bursting from their sockets. On the following morning he informed his wife that he could not see distinctly with the right eye. I did not see the patient until the following day, and he then told me that he had noticed some dimness of vision on the evening preceding the violent straining at stool. On examination I found complete right hemianopsia, the boundary of the blind half of the field of vision passing through the point of fixation. The pupillary reactions were apparently normal. At first I thought there was slight blunting of sensation and paresis of the right arm, but subsequent examination (on the following day) proved that this was probably erroneous. The patient remained in *statu quo* for ten days, when he began to have visual hallucinations on the blind side. He saw men, with whom he conversed, immense flies, spiders, and other insects, etc. For a few days he recognized the deceptiveness of these hallucinations when spoken to on the subject, but then he became convinced of their reality. The delusions were present almost constantly during his waking moments, but attention could be diverted from them at times for a little while. Vision in the opposite halves of the field of vision appeared to be perfectly normal.

The number of hallucinations increased in frequency, and at the end of a few weeks they kept constantly trooping across the blind side. At this time the patient became extremely suspicious of everyone about him, and could not be kept quiet in bed. He would walk about the rooms for an hour at a time, looking in closets and corners for the monsters that tormented him. Occasionally he would have long lucid intervals, and during these I was told by him that the hallucinations always seemed to travel from left to right, but I do not know how much credence should be attached to this statement.

Uræmic dyspnœa now became constant, and the patient was compelled to sit upright in bed while sleeping. When the asthmatic attacks were at their worst, he was afraid to fall asleep for fear that he would suffocate.

On December 14th he began to manifest the Cheyne-Stokes type of breathing, and this persisted almost continuously until death. The periods of apnœa generally lasted from thirty to sixty seconds.

On December 30th he began to suffer from involuntary twitchings of the neck, which generally drew the head violently toward the right shoulder. At the same time the entire head was red and hot. Every few minutes the patient gave utterance to the following explosive sounds—rat-a-put-a-kee, repeated a number of times, and terminating in a sort of whoop. His wife informed me that he had been in the habit of uttering these sounds years before while playing with his children and tossing them in the air.

---

[1] Read before the Neurological Section of the New York Academy of Medicine, May 11, 1888.

This condition lasted for a few days, after which it was found that the right arm and leg were paralyzed. Sensation seemed to be unaffected. The arm was much weaker than the leg, and could only be raised with the aid of the other arm. The muscles of the forearm and hand were less affected than those of the arm and shoulder.

After the occurrence of the right hemiplegia (probably on January 3d) the mental symptoms cleared up to a considerable degree, and the twitchings of the head grew less violent and continuous, but the visual hallucinations still persisted. But even when the mental disturbance was at its height it was evident that the hallucinations were seen on the right side, because the head was always turned to the right in looking at them and speaking to them.

Three days before death the twitching of the head and the restlessness again made their appearance, retention of urine occurred, and the pulse became extremely feeble. Apathy set in and deepened into coma, in which the patient died on January 15th.

The following diagnosis was made: Chronic diffuse nephritis, cardiac hypertrophy and dilatation, hemorrhage or softening of the left cuneus, and a later focus in the left internal capsule. I leaned more strongly toward the diagnosis of hemorrhage than of softening, on account of the existence of Bright's disease, the age of the patient, and the apparently normal condition of the arteries at the wrist.

The autopsy, in which I was kindly assisted by Dr. E. A. Maxwell, was made forty hours after death, and disclosed the following appearances:

The body was very much wasted; the abundant adipose had disappeared, in great part.

The calvarium was unusually thick, and the cancellous tissue firm and solid.

The dura mater was slightly adherent to the skull.

Rather more than the usual amount of subdural fluid was present. The vessels at the base of the brain were uniformly dilated and excessively atheromatous, but contained no ante-mortem thrombi, nor could I discover a plug in any of the other vessels.

The pia mater was slightly cloudy, but not more than is common at this period of life.

The cortex seemed to be normal, with the exception of the left cuneus. This presented a slightly yellowish tinge, and was boggy to the feel. On cutting through it a spot of softening was found, the interior of which contained a rather turbid serum and some fine meshes, apparently composed of connective tissue. The wall of the cyst was nearly one-eighth of an inch thick, and much firmer than surrounding parts. The cyst was nearly three-fourths of an inch in diameter, and extended forward exactly to the parieto-occipital fissure; inferiorly it extended just across the calcarine fissure, and posteriorly to within one-fourth of an inch, or perhaps a little more, of the posterior extremity of the cuneus. It extended inward nearly half an inch. The pia mater was slightly adherent in this locality. The plugged vessel could not be discovered.

In the internal capsule of the same side, at the genu, was found a small yellowish patch, a little softer than surrounding parts. In the external part of the lenticular nucleus, at the junction of the anterior and middle thirds, was a minute cavity, with sharply defined borders and without any contents. Dr. Maxwell and I were unable to decide whether this was the remains of a small spot of softening or an indication of the etat criblé.

Apart from the lesions mentioned, the brain tissue appeared to be entirely normal.

The heart was enormously hypertrophied and dilated in all its parts; it was judged to weigh about thirty-five ounces. The mitral valve was somewhat thickened, and the leaflets slightly adherent to one another.

The kidneys presented an exquisite picture of advanced chronic diffuse nephritis (small size, adherent capsule, granular surface, extreme atrophy of cortex, Malpighian bodies barely visible and apparently destroyed in great numbers, markings very indistinct, and numerous vessels with thickened walls).

With the exception of a calculus in the gall-bladder, the other organs presented no changes worthy of note.

Remarks.—This case is interesting and important in several respects. In the first place, it adds a strong argument to those already adduced by clinico-pathological experience in support of the position that the cuneus is the cortical centre for sight. Cases in which such circumscribed lesions are confined to the occipital cortex are rare, and since the publication of Seguin's very important and interesting paper, in which four cases of this kind, including his own. are collected, only one other has been reported. Even in this, which is described by Wilbrand, the lesion was more extensive than in those referred to above. It included the cuneus and entire occipital lobe behind the calcarine fissure; also the posterior half of the third temporal convolution and the gyrus hippocampi. In our patient the lesion was exactly limited to the cuneus, except that it passed across the calcarine fissure, although it did not extend into any adjacent convolution.

These cases, taken with the large number of other less decisive ones, seem to warrant the inference that lesion of the cuneus is the essential element in the visual disorder under consideration.

In one respect our case appears to be unique, so far as we have been able to discover in our unfortunately incomplete examination of the literature—we refer to the occurrence of visual hallucinations on the blind side of the field of vision. Cases have been reported in which the development of the hemianopsia was attended with faint impressions of light in the field which was becoming blind. But in these it cannot be said that the destruction of the cortical centre was yet complete, inasmuch as the visual impressions ceased when the hemianopsia was fully developed. In our case, on the other hand, the visual hallucinations—which, it is well to remember, were of a very complex character, and, furthermore, were projected into space, as is shown by the fact that the patient hunted for the spectra in closets, etc.—did not appear until ten days after the hemianoptic attack. This was at a time, therefore, when it may be assumed that the irritative process around the focus of softening (which was evident at the autopsy) was beginning to make itself apparent. This forces us to the conclusion that there must be other and higher centres for sight. We are compelled to assume, it seems to me, that the stimulation of fibres passing from the cuneus (by the irritative process around the softened spot) was conveyed to some other centre, in which, in accordance with the doctrine of the specific energy of the nervous elements, it was converted into a visual conception. The cuneus, accordingly, is a visual perceptive centre, while visual concepts must be located in some other region, probably in other parts of the occipital cortex, whose exact localization is not known at present.

This higher visual centre must possess connections with numerous other centres, because it can be stimulated through the agency of the centres of all the special senses, and also of tactile sensation.

Quite a number of instances in which the higher visual centres have been injured (so-called mind blindness or psychical blindness), either combined with hemianopsia or independent of the latter, have been reported.

Charcot describes a remarkably interesting example of the latter variety, of which we will give a brief abstract.

Mr. X——, a highly cultured man, born in Vienna, versed in German, Spanish, French, Latin, and Greek, also acquainted with modern Greek.

Until a year ago he had an excellent memory. This consisted, as also in his father and son, of a visual representation of objects. Simple memory awakened in him the images of persons, the form and color of objects, with as much clearness, distinctness, and accuracy as in reality.

If he wished to recall a certain sentence in any letter, the entire letter appeared to him as an image, which he could read like the original.

It was impossible for him to think of any portion of a drama without seeing in his mind the stage, scenery, actors, and audience. He could draw an entire landscape from memory. Memory of auditory impressions was much inferior to visual memory.

A year and a half ago he had great business worry, lost his appetite, and suffered from insomnia. One day he was frightened by a remarkable change which had taken place in himself. Although he could see everything distinctly, he had lost completely the optical memory for forms and colors.

Whenever he returns to town after a journey, it seems to him as if he has entered a strange city. He looks at the streets and buildings as if he had seen them for the first time. But memory gradually returns, and finally he can find his way in the labyrinth of streets.

He now draws buildings, persons, etc., in a very primitive manner, as if it were done by a child. He is unable to remember the physiognomies of his wife and children, and even his own person. A short time ago, while in a public gallery, he asked an individual to allow him to pass, and found it was his own image in a mirror.

Examination of the eyes revealed nothing beyond slight uniform impairment in the perception of colors.

Formerly he could add long columns of figures by mental images, now he only ventures on short columns, and repeats them at the same time in a gentle tone.

He now relies upon his auditory memory. The words seem to resound in his ears—an entirely new sensation. In order to write down a few lines which he had read in a newspaper, he was compelled to appeal to the auditory sphere. When he reads, he makes the corresponding movements with his lips, and must rely upon the inner voice and the movements of articulation in order to understand what he reads.

In order to learn a series of phrases, he repeats them several times in a loud tone, and thus impresses them upon the ear. When he repeats these phrases later, he experiences the sensation of an internal voice before articulation. This sensation he had never experienced formerly. Mr. X—— now dreams only in words, almost exclusively in Spanish.

In addition to the loss of mental images, there is also a certain degree of word blindness. The patient states that his condition has made him less impressionable to anger or grief, and less enthusiastic.

Wilbrand, who has written a very learned treatise on mind blindness, reports a very similar case, except that the condition was associated with left homonymous hemianopsia.

Quite a large number of such cases have been observed in the insane; but, as a matter of course, these do not possess the clinical value which attaches to the history of the affection in intelligent sane individuals. So far as we can judge from the teachings of pathological anatomy, the lesion of mind blindness is situated in the convexity of the occipital lobe; perhaps, also, in the posterior part of the parietal lobe, but, in the majority of cases, the lesions have been too diffuse to permit rigorous localization.

We have merely referred to this condition here, in order to awaken an interest in the subject. Without conscious attention it is apt to be overlooked, or to be mistaken for some other form of mental derangement. We know from our own experience that even such a simple condition as hemianopsia is overlooked time and again by the physician as well as the patient.

Our knowledge of this subject is still in its earliest infancy, and, even in regard to disorders of the purely perceptive centres, much remains to be learned. For example, a few cases have been reported in which cerebral lesions have given rise to crossed amblyopia, not to hemianopsia.

In conclusion, we will give a brief note on an instance of this kind, and will ask the members of the Section for their opinion on the causal lesion.

Mrs. H——, aged forty, exceedingly stupid, contracted syphilis six months ago. On Christmas she fell to the sidewalk and became unconscious. Since then, has been paralyzed in the left arm and leg, and also lost vision of left eye. Examination by my colleague, Dr. Hepburn, shows in both eyes retinal atrophy, veins normal, not tortuous, arteries smaller than normal, no choked disk. He could find no ocular cause for the blindness. In the right eye, central vision is good, but a hurried examination seemed to show impairment at the periphery.

Is the lesion in this case single or double, and where is it situated?

CASE II.—ARSENICAL PARALYSIS; MULTIPLE NEURITIS.—Charles B——, single, aged twenty-eight, native of France, fencing-master; family history unimportant. Patient drank considerably from the age of eighteen to twenty-five. Does not remember to have had any diseases of childhood. Had gonorrhœa once. Denies syphilis.

In 1883 he took a position as master in a gymnasium. His duties entailed a great deal of muscular exercise, which lasted eight hours a day. In the morning he would be very tired and hardly able to rise from bed on account of stiffness in the muscles. The back was constantly painful. He was engaged in this occupation about two months.

On July 26, 1884, he took about four grammes of arsenic by mistake. Three hours later he began vomiting severely, and had great pain in the epigastrium. The following day, he was seen by a physician, who gave him an antidote and mucilage. On this day he felt great tingling throughout the body. On the third and fourth days he was greatly constipated, rectal injections being often of no use. The pain and vomiting continued, he had some fever, and was so much prostrated that his life was despaired of. On the fifth day he vomited fecal matter once. After this the vomiting diminished, and stopped entirely on the seventh day. Constipation remained obstinate for two weeks. About two weeks, or a little earlier, after taking the arsenic, he began to have pricking sensations, formication, and very severe shooting pains, first in the upper extremities, and a week later in the lower extremities. The pains were sufficiently severe to prevent sleep, and were shooting in character, coming on every few minutes. The limbs ached greatly when free from the darts; the muscles were quite soft and tender on pressure. About three weeks after the poisoning he noticed trouble in using the hands. He could not lift a glass from the table on account of inability to grasp it, but had the power of raising the limb. Could not button his trousers or pick up small objects. At the same time noticed diminished power in the lower limbs. He could not walk well because the limbs gave way under him. At the end of the first month could not use the hands at all in picking up small objects, and the other movements of the upper limbs were also diminished in vigor. He was unable to walk, although he could perform some movements with the lower limbs when sitting or lying down. He states that the hands presented somewhat of the claw appearance; could not straighten the fingers, but could close the hand fairly well. The co-ordination of the thumb and fingers was said to be much impaired. There was a feeling of numbness, and some loss of tactile sensation in these parts. The movements at the wrist, elbow, and shoulder-joints were fair, but by no means normal. All the muscles of the arms were wasted. The pains were still intense. The pricking sensations and formication stopped in the lower limbs. The feet were extended at the ankle-joints, and the toes were strongly flexed, so that flexion of the foot or extension of the toes was very imperfect. The movements at the knee and hip-joints were tolerably fair. The muscles were wasted, soft, and very tender on pressure. The pains in the lower limbs were still severe.

At the end of the first month the patient was admitted to the French Hospital, where he was put on large doses of potassium iodide and tinct. ferri chloridi, and the actual cautery was applied to the spine once a week. Remained there thirteen months. Improvement began in the upper limbs during the fourth and fifth months after admission. The pains ceased entirely, he could use the hands better, the muscles grew firmer, and lost their tenderness. Improvement in the lower limbs did not begin until the ninth month. He then began to flex the foot and extend the toes a little. Nine months after the accident he got out of bed, and continued improving until his admission to Randall's Island Hospital, September 10. 1885.

Present condition, September 10, 1885: The patient is a well-developed, healthy-looking man; intelligence excellent; fair power in upper and lower limbs; can pick up small objects with ease, button and unbutton coat, etc.; flexion and extension of fingers not quite up to the normal; a slight feeling of numbness in the fingers, but tactile sensation apparently normal. Dynamometer: Right hand, 38; left hand, 43; has always used the left hand more than the right; electrical reactions normal.

Lower extremities: Feet partly extended and cannot be flexed on account of rigid contracture of the Achilles tendons, except when the limbs are held straight; they can then be flexed slightly. The toes are flexed, especially the big toes, from contracture of the flexor tendons. The patient does not stand well, partly on account of the flexion of the toes, partly from weakness of the leg muscles. Thigh muscles well developed, and act normally. Sensation slightly diminished on the toes; can feel a fly better than a sharp point.

Right anterior tibial nerve responds to a strong galvanic, but not to a faradic current; the left anterior tibial responds to both currents, but a stronger current than normal is required. Electrical contractions of the muscles of the anterior and posterior groups of both legs are slower than normal, and more ready to the galvanic current, very slight contraction being obtained from the faradic current, especially on the right side.

Cutaneous reflex from soles of feet is very slight. Cremaster reflex of left side is fair; of right side *nil*.

The following tendons were divided by my colleague, Dr. F. Heuel: Both Achilles tendons, the left flexor longus pollicis, and part of the left plantar fascia. Three weeks after the operation, he was allowed to leave the bed, and could walk quite well with the aid of crutches. During this time the interrupted galvanic current was applied, every other day, to the anterior tibial groups, the constant current to the calf muscles. The patient improved steadily and quite rapidly, and was soon able to walk some distance without the aid of a cane. The upper limbs also acquired their normal power, but sensation in the upper limbs, as well as in the lower, did not improve materially. The patient was soon able to perform satisfactorily the duties of an orderly.

We presume there can be little doubt that this was a case of arsenical multiple neuritis, and we shall therefore not attempt to fortify the diagnosis. Another case, of a somewhat similar character, has also come under our observation; but in this the sensory symptoms were far more prominent than the motor disturbances, and recovery was much more rapid and complete than in the case described above. We may also refer briefly to a case in which a patient, while taking arsenious acid for diabetes, suffered, in addition to the ordinary symptoms of the physiological effects of arsenic, from numbness and paresis in the distribution of the right ulnar nerve. In this case, also, we are justified in assuming the production of a peripheral neuritis as one of the toxic effects of the administration of arsenic.

Quite a number of cases have been reported by various writers, and attributed to multiple neuritis. We believe, however, that it would be one-sided to regard all cases of arsenical paralysis as peripheral in their nature. In 1880 we had under observation a patient in whom there developed, after acute poisoning with Paris green, an incomplete motor paraplegia of the lower limbs, attended with great pain in these parts, and some numbness, but also accompanied by paralysis of the bladder and rectum. In such a case it is more plausible to assume a subacute myelitis as the real lesion.

In the majority of the reported cases, however, it is very probable that the lesion was a peripheral one.

Dr. Seguin, who has reported three very interesting cases, believes that arsenical paralysis is due to diffused central myelitis, with special involvement of the anterior gray matter. We must confess, however, that the clinical histories which he furnishes seem to us to be explained better on the assumption of a peripheral than a central lesion. The chief points in favor of the former view are the prominence of the sensory symptoms, the absence of bladder symptoms, and the completeness of recovery.

The theory that arsenical paralysis is the result of a myelitis received strong support from the experiments of Popow on dogs, and in which post-mortem examination showed evidences of inflammation of the spinal cord. But these results have been disputed by Kreyssig and Schultze, who maintain that the appearances described by Popow are, in great part, artefacts, and they obtained negative results in their experiments on dogs and rabbits. Vulpian also obtained negative results in his experiments. So far as we know, no autopsy has been obtained hitherto in a case of arsenical paralysis in man.

OXALATE OF CERIUM AS A REMEDY FOR COUGH.[1]

By HOBART CHEESMAN, M.D.,

ATTENDING PHYSICIAN TO THE NORTHWESTERN DISPENSARY, N. Y.

Mr. President and Gentlemen: About eight years ago I read a paper on this subject before the County Medical Society, which was published in The Medical Record. The subject attracted some notice at the time, but I believe merits more careful and general attention than it has yet received. Since then, having had further experience with the remedy and accumulated quite a large number of cases, and, furthermore, since many of you are probably unfamiliar with that paper, I venture to present the subject to-night. To do it justice necessitates a review of the experience which is the basis of the former paper.

The importance of alleviating cough in phthisis and in other diseases is recognized. Watson says: "Cough is usually present, more or less, during all the stages of phthisis, and is often that symptom which most harasses both the patient and his family." Another authority remarks that, "in many cases, it is the chief cause of annoyance throughout the disease. The violent efforts exhaust the invalid, induce perspiration, disturb sleep, and excite vomiting; they also inflict direct injury, and, unless moderated by treatment, may hasten the course of the disease." The constant unrest caused by frequent and violent paroxysms of cough, the exhausting efforts attending them, and the direct injury done the delicate and diseased organs, not only present formidable obstacles to any possible success in treatment of the disease, but are potent active factors in hastening the fatal issue. The demand is for a remedy which can be relied on with reasonable certainty to reduce the cough to a minimum; which will not derange digestion, impair nutrition, nor disorder nervous function, but which will allay gastric disturbance and aid digestion; one which will not clog the lungs, nor lose its effect by prolonged use. Such is the ideal cough medicine, to discover which the ambitious therapeutist may still find employment. To anticipate, it it is not fully realized in the oxalate of cerium.

In 1859, Sir J. Y. Simpson introduced the oxalate of cerium for the vomiting of pregnancy. The evidence of its efficacy in this disorder rests upon testimony too general and reliable to be questioned. Ramskill has noted its successful use in cases of epilepsy, having, as an aura, some gastric commotion. Previous to 1868 it had been employed in the vomiting of laryngeal and in pulmonary phthisis, hysteria, and in various dyspeptic conditions, with good results. In 1878, Dr. Clark, of London, first recorded its beneficial effects in chronic cough and shortness of breathing, observed in several cases of phthisis. In 1879, Dr. Morjé used it, with success, in whooping-cough.

---

[1] Read before a meeting of the Manhattan Medical and Surgical Society, May 5, 1888.

According to current authority, the cerous oxalate has the power, like some other insoluble metallic powders, to allay local nervous irritability. Dr. Ramskill, of the London Hospital, thus formulated its apparent mode of action: "It is a sedative and conserver of nervous force; the sedative action, being exerted on the periphery of the pneumo-gastric, conveys the influence to the grand centre of excito-motor action, the medulla, and thus not only prevents an attack, but diminishes the chances of future ones, by lessening the morbid excito-motor sensibility."

Perhaps, not enough stress is ordinarily laid on gastric and hepatic disturbance as the cause of cough; and, especially in cases of evident disease of the respiratory organs, may not other causes be too frequently overlooked? The respiratory organs being free from disease, we are ready enough to search a disordered stomach or liver for the irritant which excites the cough. But may not the stomach and liver be just as active agents in exciting cough, when disordered during the course of phthisis, as at other times, when the lungs are healthy? It has appeared, in my experience with phthisis, that these patients are very subject to "bilious" attacks. Such attack, being attended by aggravation of cough and other distressing symptoms, may be mistaken for exacerbation of the disease. But the symptoms subside on removal of the "biliousness," like attacks of asthma in bilious subjects. This might partly explain the mode of action of the oxalate in relieving spasmodic asthma, a fact noted in a number of cases. At least, treatment of asthma directed to the stomach and liver, meets with ready response in a large number of cases in my experience. But whether much of the cough present during pulmonary disease arises from disturbance in the digestive organs or not, theoretically, the oxalate of cerium would seem an appropriate remedy for it, by its sedative action exerted through the pneumogastric.

My experience with the oxalate of cerium for the relief of cough began in 1879, at St. Luke's Hospital, during my service as house physician, and it was there that the data for my former article were collected. In order to attach proper value to the results, it should be known how they were obtained. There were at the time in the wards a daily average of about twenty or twenty-five patients requiring cough remedies. The coughing of so many made the wards very noisy at certain periods of the day, which, while harassing to themselves, was annoying to others, and a continual reminder to the physician of the inadequacy of his resources. In seeking for something more satisfactory than the conventional cough remedies, or at least, to prove whether opiates might not for the most part be dispensed with, the oxalate of cerium was put on trial. I recognized that phthisis is not the most satisfactory condition under which to test the merits of a cough remedy, knowing how intermittent the cough usually is, and that it may cease to give much trouble for long intervals without medication. In the hospital some experiments were made for which, in other circumstances, there is not opportunity, and which were particularly intended to meet this difficulty. It does not seem probable that all the patients would simultaneously experience relief, unless it were due to the drug. The effects on each patient could be observed, and simultaneously on all in the wards. As a measure of the latter, I tried to estimate whether the noise in the wards became less when all those requiring cough remedies were taking the oxalate, than when they were not. To make surer on this point its use was interrupted two or three times for several days. It evidently made a difference, for when all were taking it the wards became comparatively quiet; while within twenty-four or forty-eight hours after stopping it, increase in noise and complaining became evident. The same course was pursued in individual cases, the remedy being frequently suspended to observe the effect of its withdrawal. At first the oxalate was employed in a desultory way in a few stubborn and distressing cases, with such good effect that the more thorough and systematic trials were begun. For a period of three months all other sedatives, opiates and cough medicines, with rare exceptions, were abandoned, the oxalate of cerium alone being employed for cough; without, however, the general treatment being interrupted. Twenty-six different patients were experimented on, about sixty separate trials of the oxalate being made, none of which extended over periods of less than a week or ten days, and many of them were continued several weeks without interruption. During this time I visited the wards frequently day and night to make observations, noting them myself; also, instructing orderlies and nurses to watch particular cases and report their observations. In a matter of this kind more satisfactory results are thus possible than in private or dispensary practice, where the testimony of patients is accepted, in large part unsupported and unqualified by the physician's own constant observation.

My subsequent experience has been of this character, embracing quite a number and variety of diseases, while the hospital cases were confined to phthisis, bronchitis, and two or three anomalous conditions. But in many of the more recent cases no such complete records have been kept, and in others none at all. They have, however, on the whole, sustained the conclusions reached in the former paper, extending the scope and modifying impressions here and there, but not altering essentially the results. A few months after completing my service at St. Luke's, Dr. A. H. Smith, on reading my notes which were handed him, became interested in the subject and collected about fifty additional cases from physicians whom he induced to make trials of the remedy. These trials added nothing new except in variety. A report of results was read by Dr. Smith before the Therapeutical Society, and published, about the time of mine, in the *New York Medical Journal.* Through Dr. Smith's courtesy, these additional cases were cited in my paper previous to their being printed. Since then, so far as I know, nothing has appeared on the subject.

In over half of my trials with the oxalate decided relief to the cough, and often to other symptoms, has occurred; in some of them only moderate effects were apparent; while in a few the drug has proved nearly or entirely ineffective. Some cases do not yield readily to any measure, but often in them the oxalate has proved, after all, most satisfactory. It should be persisted in for a number of days, in increasing doses, before being abandoned as useless.

The oxalate of cerium has proved a remedy for cough in every stage of phthisis, but, perhaps, the best effects are seen in the irritant cough of the earlier stages. It is impossible to know just how much of the cough of advanced stages is due to irritation in freshly invaded portions of lung, or to gastric and hepatic disturbance. However this may be, I have often noticed a hoarse, deep, and harassing cough in the third stage lose its harsh character under the use of the oxalate, after which the cavities were emptied with less effort. It is an error, I think, to suppose that violent and exhausting cough is best left unchecked, because there is abundant secretion to remove. The cough of laryngeal phthisis has been successfully treated with it, also other forms of laryngeal cough. Dr. George Bayes reports, in a case mentioned in my former paper, that "a chronic laryngeal cough of a croupy quality was entirely and permanently relieved by its use." In the vomiting of laryngeal and pulmonary phthisis it is beneficial. In chronic bronchitis it has been used with good results, and in cough associated with an asthmatic condition, of phthisis, or of bronchitis, it may relieve both the cough and dyspnœa; and it has proved effective in spasmodic asthma, as already mentioned. An interesting case was quoted in my former article, of "a very distressing cough in empyema which immediately subsided" under the use of the oxalate, "after which the pus which was being discharged through the lungs was expectorated with less effort." It has been used with some effect in whooping-cough and in the cough of measles, and also in cases of cough of obscure origin without assignable lesion. It has been recommended chiefly in chronic cough, but in acute bronchitis my experience is that it often moderates the cough and lessens discomfort.

I have never seen any dangerous symptoms attributable to the drug, although I have given twenty grains several times in one day. A sensation of dryness in the mouth and throat is the only symptom noticed by patients, and they ceased to mind this after the drug had been taken a few days. Generally patients sleep and rest better while taking the oxalate, and in a few instances moderate drowsiness has accompanied its use. But I am undecided whether this was the direct effect of the drug, or due to the fact that "tired nature's sweet restorer" was making up for lost time. It might be supposed, the drug being a sedative, that the sedative action, being collected and transmitted by the pneumo-gastric to the grand centre of excito-motor action, the medulla, would be reflected with most effect on those functions in direct association with the pneumo-gastric, while less directly and in less degree as a general sedative.

Administering the drug dry seems the most satisfactory method. Tablet triturates I have not tried. The effects seem better when it is given on an empty stomach and in fairly large doses, rather than the same quantity distributed in smaller ones. The initial dose being five grains, to be given early in the morning, at bed-time, or both, with intervening ones as required, may be increased, unless relief is obtained, to ten grains, or more, several times a day. Large doses may succeed where smaller ones have no effect, or the cough, being for the time relieved by small doses, may return and be again moderated by increasing them. It loses its effects with continued use in some cases altogether, while in others the effects last so long, at least, as it is found necessary to employ the remedy. Its benefits may be prolonged by stopping or reducing the doses as soon as relief is obtained, and resuming them on return of the cough. One or more failures may be followed, in the same subject, with subsequent success.

Had I read all my cases instead of the imperfect conclusions, my subject might have been more fully presented; but they are too many and extended to permit it. Begging your indulgence, I will read a few, as examples:

CASE I. *Phthisis pulmonalis, second and third stages.*—J. A. S——; aged thirty-five; United States; painter.

August 13th.—Has been coughing for many weeks. Physical examination shows consolidation and softening in upper and middle portions of left lung.

August 25th.—Has had hard, loud, and distressing cough, worse at night, no vomiting. Expectorates but little and with much effort. Ordered *ten grains* of oxalate every night.

August 26th.—Coughed less and rested better last night, but coughed two or three times pretty hard.

August 27th.—Only one hard coughing spell last night.

August 28th.—No distressing cough last night; rest not broken.

August 29th.—Same report.

August 31st.—No more complaints of coughing, general condition improved.

September 2d.—Same report as to cough, which has seemed at its minimum for some time. Expectoration has suddenly become copious and characteristic, and physical examinations show a cavity in left lung.

To omit particulars, patient coughed only moderately and expectorated with little effort for two weeks.

September 18th.—More coughing, for several days, at night; night dose of oxalate increased to twenty grains.

September 22d.—Better; cough moderate, but expectoration profuse; oxalate stopped to observe the effect.

September 27th.—Five days later; worse; asking for "the powders," meaning the oxalate, but it is still withheld.

October 1st.—Coughs a great deal and sleeps little. Oxalate resumed, five grains twice a day, but a different preparation is used.

October 3d.—Distressing cough night and day; oxalate increased to ten grains twice a day.

October 5th.—No improvement; oxalate being given in water. Changed and given dry.

October 6th.—Rather better.

October 8th.—About the same.

October 12th.—No better; coughs hard and frequently. *Oxalate changed to Merck's.*

October 13th.—Better.

October 16th.—Better.

October 17th.—Passed a good night.

October 18th.—Same.

October 21st.—Improvement continues; rest is better, and improvement general.

October 30th.—Cough continues moderate, and the patient fairly comfortable.

CASE II. *Cough and dyspnœa without discoverable lesion or assignable cause.*—L. T——; aged twenty-five; United States; no occupation. Family scrofulous; she has rachitic deformity of bones; never has had good health; looks fairly well; has neurotic tendencies, which are inherited. Suffered for many weeks from severe paroxysms of cough and dyspnœa, alternating—when the cough ceases the dyspnœa is worse, and *vice versa.* Paroxysms come on suddenly after intervals of quiet; sometimes sits up much of the night coughing or gasping for breath. Recently has had several attacks of syncope.

From September 7th to the 26th many different remedies were tried in vain for the cough and for the dyspnœa. On the latter date the oxalate of cerium was ordered three times a day in ten-grain doses.

October 1st.—Five days later there was no improvement, and the oxalate was stopped. Repeated examinations of thorax, larynx, and other organs failed to discover any cause for the symptoms. The cough is loud, deep, and hoarse, of a quality suggestive of aneurism.

October 16th.—Two weeks later the oxalate was again ordered, twenty grains at night and ten grains morning and noon, but with no effect after over a week's trial.

CASE III. *Phthisis pulmonalis, third stage.*—George H——; aged thirty; United States; clerk. Family phthisical; has been complaining for a year or more. Physical examination shows cavity at right apex, consolidation at left.

October 5th.—Has annoying hacking cough, worse at night. Ordered ten grains of oxalate every night, dry.

October 16th.—Cough has been better, but of late is more troublesome again. Oxalate increased to ten grains twice a day.

October 22d.—Cough has been less troublesome for several days. Oxalate stopped to observe the effect.

October 25th.—Coughing quite hard in the afternoon, yesterday almost continuously, when the oxalate was resumed, in ten-grain doses at night and five in the morning.

October 26th.—In the evening reports: not much coughing at night, but still considerable in the afternoon. Morning dose of oxalate increased to ten grains.

October 27th.—Better. October 30th.—Same report. Oxalate reduced to five grains twice a day. Three days later patient was complaining again and continued to grow worse. A Philadelphia oxalate was used at this period. After using it fifteen days with no effect, Merck's was substituted on the 16th, five grains twice a day.

November 17th.—Some better.

November 19th.—Better, but still cough is at times annoying. Expectorates with less effort. Oxalate increased to ten grains twice a day.

November 30th.—Complains no more—is quite comfortable. On questioning the patient, who is unusually intelligent, says that the only unpleasant symptom noticed by him on taking the oxalate is a sensation of dryness in the mouth and throat, but that he ceased to mind this after taking the drug a few days. He is enthusiastic in its praise, believing that it relieves the cough much, excepting the Philadelphia preparation, which, if anything, makes him worse.

Case IV. *Localized gangrene of lung.*—Ellen B——; aged twenty-nine; domestic; Ireland. September 18th. Previously robust. Had a chill three weeks ago, followed by fever, sweating, short breathing, cough, and pain in right side of chest. Temperature, 102°; pulse, 88. Dulness and pain on percussion near edge of right scapula, and a few days later moist râles were audible in the same region. Patient expectorates a tenacious matter of brownish color and cadaverous odor, but with much effort and frequent and severe paroxysms of coughing and gagging.

September 23d.—Same symptoms. Other cough medicines stopped and oxalate of cerium substituted in ten-grain doses twice a day.

September 26th.—Better. Coughed hard but once all last night. Expectorates with less effort, and the cough is no longer teasing, and gagging has ceased.

October 1st.—Sputum still fetid. Cough has been no longer distressing. Oxalate stopped.

October 3d.—Much the same.

October 6th.—Coughing hard again. Oxalate resumed in ten-grain doses at night only.

October 7th.—Did not cough last night. Oxalate to be given in the morning hereafter instead of at night.

October 8th.—Evening cough not so troublesome of late.

October 16th.—Has not complained until to-day of cough. Last night had one rather severe paroxysm. Oxalate increased to ten grains twice a day.

October 18th.—Cough gives no more trouble.

October 25th.—Same report. To be brief, cough did not return while patient was under observation, although there was still expectoration.

Finally, I would say that it has not been my intention to raise extravagant expectations on the part of those who may use the oxalate of cerium for the relief of cough. The conclusions indicated have been stated, but I will repeat a few general ones:

1. The oxalate of cerium is a serviceable remedy for many kinds of cough, at least for a considerable time, and is very useful as an alternate with other cough medicines. 2. When it is employed opiates may be dispensed with for the most part. 3. It may be safely given, in doses of ten grains or more several times a day, for many days in succession.

244 West Fifty-sixth Street.

Smokers' Vertigo.—Dr. Decaisne recently investigated a number of cases of vertigo in smokers. Out of sixty-three patients forty-nine were between fifty and sixty-six years of age. More than half of them suffered in addition from digestive troubles, with constipation alternating with diarrhœa, insomnia, palpitations, dyspnœa, and diuresis. In a third of the number there was marked intermittence of the pulse, and granular pharyngitis, while others suffered from aphthæ, amblyopia, etc. Thirty-seven were persons who smoked habitually on an empty stomach, and these suffered from vertigo, principally in the morning. The vertigo generally coincided with suppression of perspiration and diminished excretion of urine. The treatment consisted mainly in regulating or suppressing the cause, but thirty-three out of thirty-seven patients ceased to suffer on merely refraining from smoking on an empty stomach.

EARLY STAGES OF CARCINOMA.

By B. FARQUHAR CURTIS, M.D.,

ATTENDING SURGEON TO ST. LUKE'S HOSPITAL; ASSISTANT SURGEON TO THE NEW YORK CANCER HOSPITAL.

Having recently removed two tumors at the New York Cancer Hospital (service of Dr. William T. Bull), which are of great interest as showing the earliest stages in the formation of cancer, and throwing some light on the etiology of the neoplasm, I take this opportunity of placing them on record.

Case I. *Small lipoma of thigh, containing a carcinomatous lymphatic gland.*—Mrs. S——, aged forty-eight, native of Maine, married twenty-six years, has had three children, no miscarriages. Her general health has been good, except some chronic bronchitis, and there is no history of syphilis. Her mother died of a large tumor of the liver, and her father of some abdominal tumor, the exact situation of which is not known to the patient. One sister died of an ovarian tumor, another had a "lipoma" removed from the breast.

Nine years ago she first noticed the tumor upon her thigh, which appeared without any known cause, has grown very slowly, and has given her no trouble except after considerable exercise, when she experiences a slight pain in the popliteal region, attended by slight spasmodic muscular contraction.

The tumor is situated on the posterior surface of the right thigh, over the sciatic nerve, about one inch and a half below the gluteal fold. It is soft, round, movable under the skin, elevated half an inch above the level of the skin, looking like a nipple seated on a broad round base. At the operation, on January 30, 1888, the tumor was found to extend down between the muscles like a wedge, and it was not very distinctly encapsulated. It was entirely removed.

Pathological report (kindly furnished by Dr. George C. Freeborn, Pathologist to the Hospital).—The surface of the tumor is covered with numerous excrescences, having the appearance of normal fat, and most of them are covered with a layer of blackish material. On section, what might be called the cortical zone of the tumor, is found to be composed of a series of oval and round masses. Some are the color of normal fat, while others are white, and others of a light pink color. These masses are imbedded in a mottled yellow and red material of a soft consistency. In the centre of the fatty tumor a dense, white, irregularly shaped mass, about a quarter of an inch in diameter, is found. This sends prolongations into the surrounding fat tissue. To the outer and upper side of the central mass, another of similar appearance is found.

Microscopical examination.—The bulk of the tumor is found to consist of fat tissue. The two white masses described above are found to be lymph-nodes, in which the bulk of the normal tissue has been replaced by carcinoma. This new-growth, especially in the neighborhood of the central mass, is infiltrating the fat tissue.

Case II. *Chronic mastitis with beginning carcinoma.*—Mrs. W——, aged thirty-nine, native of England, married for eighteen years, has had one child, and five miscarriages since, the last ten years ago. Family history negative. General health good, no uterine trouble or history of syphilis. Menstruation regular, but attended by some pain. There is no history of abscess of the breast or of any injury. She first noticed a lump in her breast four and a half months ago, when her attention was attracted to it by a dull aching pain. The lump was about the size of a bean when discovered, and increased in size very slowly. For the last two months she has had pain in the breast and in the arm. The tumor is situated in the upper and outer quadrant of the left breast, and consists of several nodules which are very sensitive to pressure. The mass is freely movable and not adherent to the skin. There is no local heat, or discoloration of the skin, and no discharge from the nipple. There is no retraction of the nipple. The most prominent point of the tumor is a hard globular nodule, rather more than half an inch in diameter, lying close under the skin, feeling like a tensely distended cyst, but without fluctuation. The axillary glands are apparently not enlarged. The other breast feels slightly indurated, but no distinct tumor can be felt.

Operation, March 10, 1888. An exploratory incision through the cyst showed the latter to have hard, rigid walls, with an irregular interior surface, and to contain a dark brown fluid with flakes of lymph. The underlying portion of the breast was almost as hard to the knife as scirrhus. The entire breast was removed, and, as enlarged glands were then felt in the axilla through the incision, the axillary contents were also removed.

Pathological Report (by Dr. Freeborn).—Section of the breast shows the entire gland to be composed of a dense white tissue. On the edges of the gland several cysts are found, measuring from one-quarter to one inch in diameter, of a dark red color, and on section they are found to be filled with a grayish granular mass of soft consistency.

Microscopical Examination.—Sections from various parts of the gland show a marked increase of the connective tissue. The ducts are dilated. The membrana propria of the ducts, and the connective tissue in the vicinity are infiltrated with small round cells. The walls of the cysts are found to be composed of loose connective tissue, infiltrated with small round cells. In the vicinity of one of the cysts (the subcutaneous cyst described in the clinical examination) a nodule of tissue, composed of large granular cells arranged in narrow alveoli and surrounded by a stroma of connective tissue, is found. The accompanying lymphatic glands exhibit simple hypertrophy. Anatomical diagnosis—chronic mastitis with commencing carcinoma.

Both patients made a good recovery, but, of course, it is too early as yet to look for recurrence. The early operation and thorough removal warrant an excellent prognosis.

The remarkable family history of the first patient is of great interest, for it is not often that such marked heredity has been observed. It is noteworthy, also, that both cases bring confirmatory evidence to the theory of continued irritation as a cause for cancerous growths. In the first case, the small lymphatic gland was probably irritated by the increased pressure of the lipoma, situated in a part of the body exposed to constant pressure in sitting. In the second case, the tense cyst would also exert great pressure upon the chronically inflamed tissue around it, and would be a constant source of irritation. It is to be noted that the mastitis gave no symptoms of its existence until this cyst developed.

The practical deduction to be drawn from these cases is the importance of looking upon all benign tumors with suspicion, and of removing them at the very first indication that they have begun to cause irritation. In cases of chronic mastitis, if it is ever possible to recognize the condition before any cysts or tumors have formed, the patient should be warned that the breast should be removed at the first moment that any true new-formation of tissue can be detected, or any cysts develop. An ounce of prevention is worth a pound of cure, and any woman with a benign tumor of the breast will live a life clouded with apprehension until the tumor has been removed.

AN INDUSTRIOUS SURGEON'S CARRIAGE.—According to a correspondent of *The Lancet*, M. Peau, of Paris, pushes so far his love for work that he has had his coupé so arranged as to enable him to study, eat, sleep, and even make his toilet therein. Surgical instruments, books, writing material, drawers full of notes, and a chest for linen and clothes; in fact, there is everything in this elegant carriage that might serve as a model for the carriage of an army surgeon in campaign.

MEDICAL CASES IN THE COURTS.

By HENRY A. RILEY, Esq.,

NEW YORK.

THERE is a very wide range in the decisions of judges regarding the admissibility of evidence, whether this relates to verbal testimony or the introduction of some inanimate article.

In a recent case in Connecticut, the suit was for damages on account of personal injuries, caused by a person driving into the plaintiff's wagon, and throwing her out and breaking a rib. The defendant, in order to contradict the plaintiff's testimony, offered to show the exact location of the ribs in the human system by means of a section of a human body, but the judge decided that, such an exhibition being unnecessary and offensive, it was a proper exercise of discretion for the court to refuse it.

In another case, in a New York court, where the action was for breach of warranty of a horse, an impression of his mouth, in wax or plaster, was held to be competent testimony. It was considered to be "classed as a species of evidence with diagrams, drawings, and photographs."

Another case, and a more amusing one, is narrated in a legal journal. The question to be decided was the ownership of a dog, and, as the evidence was conflicting, the judge, toward the end of the case, had the animal placed beside him on the bench while the plaintiff went to the far end of the room and called out "Sam, Sam." No sooner did the dog hear the voice than it ran through the crowded court-room, and began to gambol about the plaintiff. The judge thought this was satisfactory evidence, and decided that the dog belonged to him.

The Morris Plains (N. J.) Insane Asylum shows, under the investigation by the committee appointed by the Legislature of New Jersey, a most alarming condition of mismanagement. A sample of the testimony of the various witnesses is given in the following report in the daily papers: "David Edwards, the next witness, said that he had been the butcher in the asylum for the last five years, and severed his connection with the institution about two weeks ago. He said that the meat used in the institution came from the Newark Beef Company for the last three years. In October, 1887, the Newark Beef Company shipped six carcasses of beef which weighed 4,078 pounds to the institution, all of which was spoiled when it was received. He called Warden Monroe's attention to the bad condition of the meat, and the Warden told him to do the best he could with it. In the same month the Newark Beef Company shipped twenty-five cases of veal. One-half of this shipment was in bad condition, being tainted and having a bad odor. A portion of the meat was green and decayed. Witness called Warden Monroe's attention to this fact, and was again told to do the best he could with the meat.

"The witness further stated that in December last he received from the Newark Beef Company sixty-five head of sheep, and that this meat was in bad condition. In February last he received forty-four car-loads of mutton from the same company, which was in poor condition, a portion of the meat being black. The warden told the witness to cut up this meat as quickly as he could. The witness knew the meat to be bad, but had to obey the warden's orders.

"George Butchard, another witness, said that he was employed as carver in the kitchen from September, 1887, to March, 1888. He served food to the patients under the warden's instructions. The meat was very poor and sometimes in a decayed condition when sent to the kitchen to be cooked for the inmates. The attendants often picked out the worms found in the breadstuff and sent them back to the witness in the kitchen. At this point Counsellor Corbin, for the physicians who instituted the charges against the warden, said that he would not introduce any more testimony, as he believed that his clients had produced sufficient proof of their charges. The investigation was then adjourned until June 1st."

Physicians, like most persons in good circumstances, travel in sleeping-cars, and they will be interested in a recent Louisiana case which holds that the railroad company is not responsible in damages when a porter assaults and, without provocation, beats a person who enters the car for the purpose of asking the privilege of washing his hands. The Court says: "We do not lose sight of the fact that plaintiff was not a trespasser, but had a right to enter the car for the purpose of asking permission to wash his hands, or of trying to hire the privilege, and that in addressing the porter he was dealing with him as a servant of the company. This emphasizes the outrage to which he was subjected, but would be dangerous ground for holding the employer responsible. A person has the right to enter a bank for the purpose of collecting a check, and to present it to the paying-teller for payment; but if, on such presentation, the teller should leap over the counter and knock him down, surely such an act would not subject the bank to liability. So one may lawfully enter a store and deal with any clerk with reference to the purchase of goods, but if, on some dispute, the clerk should commit assault and battery upon him, the merchant would not be responsible therefor." The courts hold sleeping-car companies to a strict liability for valuables taken from the berths, but an assault by a porter is held not to lay them open to a suit for damages.

One of the most interesting subjects to a physician is that of fees and their collection, and the profession will no doubt read with attention a statement of the experience of Dr. Milton Josiah Roberts, of this city. The report of the case, as given in one of the daily papers, is as follows:

"Charles C. Lloyd, of Cleveland, O., had a little daughter four and one-half years old, suffering from a disease which no doctor whom he had consulted was able to cure. He brought her to this city, and on January 1, 1884, made a contract with Dr. Milton Josiah Roberts, by which the latter was to treat her for a year, and was to receive $700 for his services. He treated her for nearly four months, and then her father removed her from his care and refused to pay a balance of $350 which the doctor claimed. Dr. Roberts sued for this amount with interest, and, on a second cause of action, demanded $56 more for constructing a machine to regulate the movements of the child. The case was in the Superior Court before Justice Truax and a jury. The defendant said that the contract was terminable on his expressing dissatisfaction with the treatment, and that he was dissatisfied. He denied that he was properly chargeable with the cost of the apparatus used by the physician. The jury gave the plaintiff $431.38 on the first cause of action by direction of the court, and on the second, found for the defendant."

Persons very frequently forget to pay their life insurance premiums until after the date when they are due, and if the money is received under such circumstances, the insurance companies usually require a statement that the person is in "good health," or has not been "sick or afflicted with disease" during the lapsed period. The latter statement, in a recent New Jersey case, was held not to be necessarily false because the insured had a "cold." There was nothing in this fact which required the inference that the insured had been "afflicted by disease," or even "sick." These terms are not to be construed as importing an absolute freedom from any bodily ailment, but rather of freedom from such ailments as would ordinarily be called disease or sickness.

Quite an amusing case was recently reported in a Georgia court, where a famous patent-medicine company was the defendant and the beaten party. A newspaper published what purported to be a voluntary interview between the plaintiff and a reporter, in which the plaintiff is represented as having made statements to the effect that her mother, having been bitten by a cat, was afflicted with a disease similar to hydrophobia; that she dreaded the approach of water, suffered extreme pain, and was much swollen in her body and limbs; that she acted like a cat, purring and mewing, and assuming the attitude of a cat in the effort to catch rats, and did other like acts; and that a wonderful cure of this disease had been effected by a certain medicine called S. S. S., which was sold by the defendants.

The newspaper report was held to be libellous, but certainly the reporter had a vivid fancy in devising the interview.

Clinical Department.

THE EVACUATION OF MAMMARY ABSCESSES THROUGH THEIR NATURAL OUTLETS.

By G. W. SQUIRES, M.D.,

EAST AVON, N. Y.

Among the manifold accidents that befall the puerperal woman, few are more aggravating than abscesses of the breast. They cannot always be prevented, but it falls to the lot of some practitioners to meet with more of them than do others. Abscess of the breast is produced by retention and pus transformation of the secretion of the mammary glands. The milk is deposited during the interval of nursing in the dilated tubes or reservoir of the lactiferous ducts, of which there are fifteen or twenty, located in the breast at the base of the nipple. These tubes on entering the nipple contract to very small calibre, pursue a straight course to its summit, where they open individually by slightly raised circular rings, and are lined by a continuation of the nipple membrane. Now, from some reason or other, there appears a hard lump in the breast, the alert nurse discovers it and informs the attending physician of the fact. It is an engorged milk-duct or overfull reservoir. There have been many causes assigned for its production, but the most plausible is irritation of the nipple, which extends into the small exit-ducts, closing them up, perhaps only one or maybe several. The source of the irritation may be due to a change of the normal secretion of the child's mouth, or to a lack of care to dry and lubricate the nipple after the application of the child. It may be so hyperæsthetic as to cause the mother intense suffering every time she nurses her baby. When the breast-pump is applied the orifice of the duct corresponding to the location of the lump, if examined with the aid of a lens (as a watchmaker's lens), will pout out, appear swollen and closed up, preventing the escape of the contents of the pent-up reservoir, and as there is no connection between the lactiferous tubes, there is no other avenue of escape, and the result is the formation of an abscess. Now, the treatment I propose is to dilate the tubuli lactiferi of the nipple and draw off the milk, if done early enough, or pus, if such has formed. I have succeeded by dilating with a small silver probe and applying the breast-pump to relieve the engorgement, and have seen with a lens pus flow from the dilated duct when the breast-pump was applied. The better way is to use the capillary catheter with glass receiver and hand-bulb exhauster attached, invented by John Ward Cousins, of London, England. By this instrument an engorged duct or abscess can be evacuated through the duct of the nipple, without being obliged to lance the breast. This is a nice little operation, but by a little patience and practice, with the aid of a good lens, the orifice of the closed duct can be located, dilated, and catheterized, and thus the milk or pus contained in the pent-up tube or reservoir may be removed.

Gingival Chancre.—Dr. Girode reports, in *La France Médicale* of March 20, 1888, a case of syphilitic chancre engrafted upon a gingivitis, due to the action of phosphorus.

OXALATE OF CERIUM IN SEA-SICKNESS AND OTHER DISORDERS.

By W. H. GARDNER, M.D.,

SURGEON, U.S.A., FORT M'HENRY, MD.

In the article on "Sea-sickness," in The Medical Record of March 24th, nothing is said about the use of oxalate of cerium in this distressing disease. Now I have been a traveller by land and water ever since I was able to toddle around, and have met many cases of sea-sickness—in stages, ambulances, cars, boats, and ships—and I can confidently assert that oxalate of cerium administered in ten-, fifteen-, or twenty-grain doses, every two or three hours, in about one tablespoonful of water, will cure more cases than champagne, bromide of potassium, chloral, or anything else I ever tried. I do not think I exaggerate when I state that it will cure, or materially relieve, seventy-five per cent. of all cases that come up for treatment.

I was induced to use this remedy, in these seemingly large doses, by a patient with gastritis following a debauch, who came before me years ago. I had given him pounded ice, chloral, bromide of potassium, creosote, hypodermics of morphine, mustard over the stomach, and all that the books prescribe or the ingenuity of the profession has devised; then I prescribed six powders of oxalate of cerium, five grains each, one powder to be taken every two hours in a tablespoonful of water. I went to see him six hours afterward, and found his stomach quieted, and he was drinking some iced milk. I found he had taken the first powder (five grains) and had thrown it up, so he took the remaining five powders at one dose (twenty-five grains) and it quieted the stomach at once, and he got well immediately. Shortly afterward I was called to see a man who had been shot in some little discussion over a game of cards; the ball—thirty-one calibre—entered on the right side of the abdomen, ranging upward, backward, and to the left, not wounding the bowel, but probably some branches of the solar plexus, and lodged somewhere in the muscles to the left of the spine; there was little or no hemorrhage (external), and when he recovered from the shock, under the use of ammonia, brandy, and digitalis, the most persistent symptom was the continuous and exhaustive vomiting, which, however, was controlled in about twenty hours by the use of ten grains of oxalate of cerium in a tablespoonful of water every three hours. The man made a speedy and good recovery, and is still driving a stage-coach in Arizona.

I have used the oxalate in hundreds of cases of sick headache, and the morning sickness of pregnancy, and almost always with marked success; but it must be used in at least ten-grain doses for adults, to do any good. I have also found it very useful in relieving the cough of phthisis in these doses. I do not pretend to know its *modus operandi*, but believe it acts as a sedative to the pneumogastric and sympathetic system of nerves, and I have never seen any unpleasant effects from its administration in twenty-grain doses every three hours.

A BULLET WHICH HAD PASSED THROUGH THE ABDOMINAL WALL DISCHARGED PER ANUM.

Dr. J. O. Stewart, of Cedarville, O., reports the following case: "Laura B——, aged sixteen, colored, was shot on August 2, 1887. The ball, which weighed sixty-eight grains, penetrated the abdomen to the right, and a little above the umbilicus. The opening made by the ball was round, and was not probed beyond a depth of one inch. The wound was washed with water containing carbolic acid, and absorbent cotton with adhesive plaster was applied. The patient rallied well from the shock. The treatment was directed toward absolute rest. The bowels moved eighteen days after the accident. Urine, during this time, was dark, and contained a substance like coffee-grounds. She vomited occasionally during the whole time of her confinement to bed, which was about three months, and at times the vomited matters contained a little blood. Her temperature frequently was as high as 105°, and was kept down by antifebrin administered freely, in doses of about five grains, every three to five hours. The ball was passed per anum on the thirty-sixth day. It was considerably altered in shape, and was indented in several places. The patient was under the care of my father, Dr. J. M. Stewart, and was seen frequently also by myself."

HYOSCYAMINE IN THE TREATMENT OF THE INSANE.

Dr. W. A. McCorn, of the New York City Asylum for the Insane, Ward's Island, writes: "In a recent issue of The Medical Record is noted a fatal result from the use of hyoscyamine in one-twelfth of a grain dose, by Dr. Johnson, of Toronto. I have had considerable experience in the use of the drug, and believe it to be a useful remedy, particularly in the treatment of the insane. A fatal result from hyoscyamine is of extreme rarity, and as yet the first case is to be recorded in this institution, where it is used extensively. It is administered subcutaneously, in doses varying from one-twentieth to one-fifth of a grain, Ulrich's amorphous sulphate always being used. It has proved itself to be very efficacious in quieting the motor excitement of acute, chronic, and recurrent mania, and in senile dementia with destructive proclivities; but it is not as good an agent as chloral hydrate in general paralysis of the insane. It is a drug usually considered dangerous by asylum physicians, but unjustly so, as it is much less liable to be attended with unpleasant symptoms than are chloral and the bromides. As is the case with other narcotics, those to whom it is given become gradually habituated to its effect; but it is always well to begin with a small dose, as one-twentieth of a grain, and increase as necessity demands. In all cases that I have seen, where untoward symptoms have manifested themselves, they have yielded readily to the use of stimulants."

Stretching the Optic Nerve, writes Dr. W. B. Meany in *The Lancet*, is alone practised by De Wecker, whose performance of which I had the pleasure of witnessing in a patient with marked ataxic symptoms, suffering from gray degeneration of the optic nerve. There was no pupillary response; field of vision limited concentrically; papillæ simply atrophic; chromatic reflections. The vision of the left eye was lost. Stretching of the optic nerve was practised in the left or lost eye. The eye (left) was rotated toward the temporal side; a conjunctival incision was made near the insertion of the internal rectus, the tendon of the muscle divided, and the capsule opened and freely loosened. The instrument for stretching—resembling a diminutive obstetrical forceps—was introduced so that the little blade or hook at its extremity encircled the optic nerve; then the other blade or branch was also introduced, when the two were closed, the optic nerve resting in the concavities of the two blades. A slight lifting of the eyeball concluded the operation, the blades being then withdrawn. It was observed that the operation left no other appearance than that usually met with in an ordinary tenotomy, except that the pupil remained dilated. The operation was performed under antisepsis and cocaine.

Administering Quinine by the Skin.—Dr. F. A. Carter writes to the *N. C. Medical Journal*, that if one use an oleate of quinine he will have no trouble in securing its ready absorption. "I," he adds, "have repeatedly caused cinchonism about as rapidly in the case of children by this method of administering quinine as by giving it by the mouth. Four minims of a twenty-five per cent. oleate correspond very nearly to one grain of the sulphate, and twenty minims can be absorbed by the skin of the abdomen in a very few minutes and with very little friction.'

Progress of Medical Science.

Sporadic Cretinism.—At a recent meeting of the Harveian Society (*The Lancet*) Mr. Edmund Owen showed a case of sporadic cretinism which had been sent to him by Dr. Davson; the child, aged five and a half, had been born in the Hampstead district, of healthy parents. She looked about three or four years younger than her actual age. She had been weaned at three years, but was still fed from the bottle. Among the chief clinical features were the large mouth and protruding tongue, and the absence of all trace of thyroid gland, the presence of diffuse tumors over the subclavian triangles, and of large and rounded limbs. The child could not walk or stand, neither could she speak. Reference was made to a valuable paper which was contributed nearly forty years ago by Mr. Curling, on two similar cases, in which he suggested that the physical and intellectual defects in these children were probably due to absence of the thyroid gland, depriving the economy of certain assimilation processes. Mr. Owen then referred to the works of Cocher, Ord, and Horsley upon the subject of cretinism, which he called the myxœdema of childhood. He was of opinion that the characteristic deposits in the neck, as also those which shrouded the muscles of, and thickened the limbs, were the result of mucoid infiltration of the subcutaneous tissue, and were not of the nature of fat. He concluded by calling attention to the importance of Mr. Horsley's vivisection experiments upon monkeys, by which it had been amply shown that the removal of the entire gland was likely to be followed by progressive myxœdema. Mr. Horsley thought the case a striking example of the disease. With reference to the kind allusion of the president to his own work, he wished to mention that Munk, of Berlin, had challenged his results. As he would take another opportunity of replying to Munk's statements (which could be easily explained), he wished only to remark on what appeared to him to be the most pressing problems connected with the destruction of the thyroid in these cases. There are three forms of the one disease resulting from atrophy of the thyroid. They are: (1) Intra-uterine cretinism—child always born dead; (2) sporadic cretinism of childhood, in which there is early extra-uterine loss of the gland; (3) adult cretinism, or myxœdema of middle life. Now, we are familiar in the last form with the congestion of the gland, its invasion by leucocytes, and its subsequent atrophy, with destruction of the gland tissue; but we are ignorant of what like destroying changes occur in the thyroid in the first two forms. The solution of this question he desired to urge on the attention of pathologists. In conclusion, he agreed with Mr. Owen that the resiliency of the arms seemed more than fat of connective tissue would account for, but he thought we must be very cautious in estimating the amount or existence of mucin, for, as he had himself shown, this element in the case is wanting where the chronicity of the disease is notably increased.

The Liver the Excretory Organ for Iron.—The way in which iron introduced into the body is excreted being somewhat obscure, Dr. Zalêski, of Dorpat, has endeavored to clear up our knowledge of the subject by some very carefully planned experiments. He first took two rabbits of the same litter, as nearly as possible of the same color and weight, and reared them under similar conditions, taking care that they had access to no food or drink containing any iron. When they were ten weeks old they were kept without food for four days, being allowed water only. Into the jugular vein of one of them was then introduced a solution of sodio-tartrate of iron, containing a known quantity of metallic iron. No symptoms of acute poisoning occurred during three hours. At the end of that time the carotid artery was opened, and as much blood as possible removed. The whole vascular system was then thoroughly washed out by means of a special apparatus which is used for this purpose in the Strassburg Pharmacological Institute. The liquid employed was a warm weak solution of sugar, which was introduced into the aorta and allowed to run out from the portal end. This washing out was continued till the red tint of the muscles and other organs had disappeared so completely that the spectroscope detected no hæmoglobin lines. The other rabbit was also deprived of blood in precisely the same way. The organs of the two animals were then examined chemically, and the iron contained in them accurately estimated by the volumetric method. The result showed that the only organ in which the percentage of iron was markedly increased in the animal into whose system the sodio-tartrate had been introduced was the liver, the dry substance of the organ containing 0.0998 and 0.1723 per cent. of iron in the two animals respectively. A similar research was subsequently carried out in the case of two kittens. Here the livers contained respectively 0.0431 and 0.0895 per cent. of iron, most of the other organs showing more iron in the animal into which none had been introduced than in the one in which the sodio-tartrate had been injected. The most remarkable instance of this was the muscular tissue, which in the kitten that had had no iron showed a percentage of 0.0206, and in the one which had had iron only 0.0073. Of this curious fact Dr. Zalêski does not see his way to offer any explanation, and it certainly appears somewhat paradoxical. In both the rabbits and kittens it was plainly demonstrated that the walls of the stomach and intestines contained no more iron in the animals which had been subjected to the intravenous injection than in the others. The result of the research would appear to suggest that the liver has some claims to be considered the excreting organ for iron.—*The Lancet.*

Angioma of the Epiglottis.—Dr. C. M. Desvernine reports an example of pedunculated angioma of the epiglottis. The patient was a man, aged fifty-three, of robust constitution, who for two months before he came under notice had suffered from occasional slight bleeding from the throat. On November 14th he lost a large amount of blood, and the hemorrhage only ceased on syncope supervening. Laryngoscopic examination showed an ovoid tumor of lobulated appearance and dark-blue color, and measuring two centimetres in length by one in breadth, springing from the laryngeal surface of the epiglottis to the left of the middle line, about midway between the base and the apex. The tumor was attached by a short pedicle, and there was no infiltration of the tissues around its root. On November 27th, the pharynx and larynx having first been anæsthetized with a concentrated solution of cocaine, the tumor was removed with the galvano-caustic snare. The only trace of the operation was a small eschar, which came away a few days later, leaving the site of the tumor completely healed. Microscopic examination showed that it was an angioma enclosed in a fibrous capsule.—*The Lancet.*

The Pathology of Uric Acid.—Since the discovery of uric acid by Scheele in 1776, theories have assigned to this body a variable *rôle* in general pathology. At first it was regarded solely as a "concreting" acid formed in the kidney, which bound together the earthy matters of the urine to form a stone; hence its synonym, *lithic acid*, which is still frequently applied to it. The fact that gouty deposits also contained it led Murray Forbes, in 1798, to suppose that it was formed in the general fluids of the body, and not in the kidneys. The earlier views, up to the brilliant discovery of Garrod, who first detected urid acid in the blood of gouty patients in 1848, regarded the association of uric acid with gout as the result of physical rather than of chemical changes, and spoke of the formation of gouty tophi more as a consequence of insoluble material being deposited, than of a specific inflammation leading to increased formation, by chemical changes taking place in the tissues, either generally or locally. Even at the present day, evidence exists that this early view has considerable influence over the minds of some who are recognized as authorities on the subject. In fact, it is still possible to separate the teachers into two schools, the chemical and physical: the one holding that the chief relation of uric acid to gout depends upon an increased formation in the body; the other referring such relationship simply to the insolubility of uric acid and its tendency to deposit in parts of little vascularity under circumstances which retard its elimination or prevent its destruction. In England, the chemical school has the larger, if not the more influential following, owing, no doubt, to the advocacy of Garrod, Murchison, and Latham; on the Continent, however, the supporters of the physical theory are more numerous, and there is increasing evidence that their teaching is beginning to spread more widely in England. The latest addition to the teaching of the chemical school is that of Dr. Latham, whose Croonian Lectures of 1886 explained the whole *rôle* of uric acid so far as concerned its relationship to gout, rheumatism, and diabetes—that is, if the whole of his hypotheses can ultimately be sustained by facts. Indeed, so far as we can judge, he is probably correct in his assumption that uric acid is formed in the body as he describes, viz., by the conjugation of residues of glycocine with residues of urea. But we think he throws too much stress on the part played by the liver and kidney to be quite in accord with clinical experience. As is well known, he accounts for the presence of urate of sodium in the blood by the imperfect metabolism of glycocine. "Unchanged, it passes from the alimentary canal or elsewhere into the liver; there, under the action of the gland, it is conjugated with urea, and is converted into hydantoin; it then passes on to the kidneys, to be combined with other molecules of urea or bi-uret, forming ammonium urate, a portion of which overflows into the circulation, and is converted into sodium urate." Now, as a matter of fact, in frank gout at all events, the first appearance of the disease is not in the kidney but at the extremities, in the small joints, and it is not till repeated attacks have occurred that we usually have evidence that the kidneys are affected. Undoubtedly in some cases we have evidence that renal changes in the form of nephritis and lithiasis precede the arthritic inflammation, but these are commonly witnessed in the anomalous and irregular forms. In accepting Dr. Latham's views, then, with regard to the formation of uric acid, we do so with the belief that the hypothesis should be made to include the possibilitp of the conjugation taking place in other organs and tissues besides the kidneys. Some writers have extended the *rôle* of uric acid beyond that of association of gout, rheumatism, and diabetes, and would attribute eczema to a rush of uric acid to the skin, headache to a rush of uric acid to the brain, and it has even been stated that urate of sodium has been found deposited on the valves of the heart. We are not aware of any well-authenticated observations that have proved, like those of Garrod in acute gout, the presence of uric acid in the blood of patients suffering from eczema or from megrim. In the absence of such proof we may be excused if we hesitate to believe that uric acid is necessarily concerned in their production. With regard to the skin, we have evidence of the excessive formation in some cases of lactic and butyric acids; and with regard to many forms of headache, the altered reaction of the urine points to some diminished alkalinity of the blood as a sufficient reason; while, with respect to the deposit of uric acid on the valves of the heart, evidence is conflicting. Those deposits that we have had the opportunity of examining have, on chemical investigation, proved to consist of crystals of cholesterin. The physical theory of gout assigns to uric acid a far humbler *rôle* than the chemical. Without denying the possibility that in gout an excessive formation of uric acid occurs, it attributes the phenomena of the gouty seizure more to local influences, and may be thus briefly formulated: Supposing an anomalous formation (Ebstein), or an accumulation in the textures (especially the fibrous) brought about either in connection with a tropho-neurosis, or, as some believe, by vital decay, some of the tissues of the body hold more uric acid than can be destroyed. In the more vascular parts this excess is washed away by the more rapid current, and appears in the blood; while in the least vascular, the cartilages of the joints, especially those more remote, the force of the blood-current is too feeble to insure removal, and consequently an attack of gouty inflammation ensues. With repeated attacks the system gets more and more saturated with the accumulated uric acid, the larger joints become invaded, and the straight tubules of the kidneys blocked sooner or later with uratic deposit. There is much to be said in favor of this view. The facts that frank attacks of gout commence usually, unless determined to a larger joint by a sprain or other injury, in the most remote and smallest joints, and also that attacks are more frequent in limbs that have been injured or have had their activity impaired, as Ebstein has pointed out as of frequent occurrence in paralyzed persons, the joints of the paralyzed limb being always more deeply implicated than its fellow, go a long way to support the mechanical theory. Even in cases where the kidneys are affected before any arthritic outbreak occurs, the theory of stasis is sufficient to account for the phenomenon, since the deposition of the sodium urate does not occur in the proximal part of the tubule, which is the most vascular, but at the distal, which is the least. The determination of the attack to the kidneys and not to the small joints in some cases is accounted for, by the physical theory, by some undue acidity of the urine causing deposition of urate in the tubule, and not to an increased conjugation of hydantoin and bi-uret in the vessels of the kidneys. Probably on this theory of stasis a more chemical one may be grafted, for it is very likely that diminished alkalinity of the fluids and tissues, such as is well known to occur in gout, is concerned in aiding the deposition of a substance so insoluble as sodium urate, though without the aid of some local stagnation it may be doubted whether that alone, as some writers have suggested, would be sufficient.—*The Lancet.*

KREMVANSKI'S TREATMENT OF PHTHISIS.—Dr. Albitski reports a case of pulmonary phthisis treated, according to Kremyanski's method, by inhalations of aniline oil, a special diet, and the administration of antifebrine. At first the drugs and regimen were very badly borne, but soon the patient became accustomed to them, and then began to improve rapidly.

THE BLOOD IN DIABETES.—Lépine has recorded a case of diabetes which terminated fatally in coma, and in which, for the first time, it was positively shown that in this state the blood loses its alkaline reaction (*Revue de Médecine*). As far back as 1883, at the debate on diabetes at the Pathological Society, Dr. Ralfe first drew attention to the fact that the symptoms of diabetic coma were not unlike those produced in animals poisoned by an injection of acids into their veins, or whenever attempts were made to diminish the alkalinity of the blood by other means; whence the speaker inferred that the poison concerned was of an *acid* nature, which by decomposition in the urine became converted into acetone. This idea of "acid intoxication" has since been generally adopted, and Minskowski has discovered the presence of an acid (oxybutyric) in diabetic urines which is capable of breaking up in aceto-acetic acid, and thus furnishing acetone. This acid does not, perhaps, exist in the blood and tissues in a free state, but is probably combined with some base with which it forms an acid salt In Lépine's case, intravenous injection of a saline fluid containing about an ounce each of sodium chloride and sodium bicarbonate to three pints of water was employed when the coma first set in. After this there was some immediate improvement from the coma, the pulse rallied, the temperature rose from 96° to 97.5° F., and the patient could speak, but not swallow. Twelve hours afterward venesection was employed prior to the trial of a fresh injection, when it was found that, in spite of the previous injection of a large quantity of alkali, the reaction of the blood was neutral—a clear proof, Professor

Lépine thinks, of the acid nature of the disease, and its power to destroy the normal alkalinity of the blood. It may be a question, however, says *The Lancet*, whether the injection of an alkaline bicarbonate into the blood in diabetic coma is a right procedure. For, though the reaction of the salt is alkaline, yet its constitution is acid, and, as Dr. Ralfe pointed out some years ago, probably acts as an acid salt in its decomposition with other salts in the body, and so actually tends, after the immediate effect of its alkalinity has passed off, to diminish the alkalinity of the blood. Should this on further inquiry prove correct, it might be advisable to employ neutral sodium phosphate instead of the acid sodium carbonate for intravenous injections.

Professor von Bergmann's Method of Antiseptic Treatment.—Dr. F. Bramann, first assistant surgeon to the Surgical Clinic of the University of Berlin, reports on the antiseptic treatment adopted by Professor von Bergmann (*Archiv für klinische Chirurgie*, vol. xxxvi., 1887, and *Centralblatt für die gesammte Therapie*, December, 1887). Sublimate gauze is prepared by exposing gauze during one quarter or half an hour to a continuous stream of water-vapor of 100° C. (212° F.), after which it is rapidly dried and impregnated with a solution of sublimate. Plain sterilized gauze is but rarely employed, and only in minor operations. The cotton-wool used for dressing is not impregnated, but merely sterilized by steam in the above manner. The water-proof sheets, linen sheets, napkins, towels, and sponges are disinfected in the same way. Small rolled-up pieces of sublimate gauze are generally substituted for sponges. The silk for sutures is sterilized; catgut is immersed for from ten to fourteen days in an alcoholic solution of sublimate (4 : 1,000), and afterward kept in a solution of 1 : 800 of sublimate in alcohol and 200 parts of distilled water, in which the catgut will not become brittle. The wound during the operation is irrigated with sublimated water (1 : 2,000); but in operations in the abdominal or pleural cavity the wound is merely wiped with pieces of sublimate gauze. In the mouth, rectum, and in the bladder, instead of sublimate, salicylic acid (1 : 1,000), boric acid (2 : 100), and at the termination of the operation iodoform ether (1 : 10), are employed. The instruments are left half an hour before use in a solution of three per cent. of carbolic acid. Hæmostasis is most carefully attended to, and the wound is not closed before the slightest trace of bleeding has disappeared, by which precaution the best results even without drainage are achieved; but there are exceptional cases in which the hæmostasis cannot be perfect and the wound cannot be kept free of serious oozing, or in which an aseptic progress is doubtful. In such cases, the wound is irrigated with a 1 : 1,000 sublimate solution, rinsed with iodoform ether, and loosely tamponned with a strip of iodoform gauze, the end of which is brought out in the corner of the wound, and is dressed over the tampon with sublimate gauze and cotton-wool, according to antiseptic rules. Should the dressing become saturated with the discharge of the wound, the external layers are to be renewed, but the iodoform gauze is left for two days, after which it can be easily and safely removed. The wound is now accurately closed by sutures, and union by first intention will take place even in cases in which the tampon had been left, owing to special reasons, for four to six days.—*London Medical Record.*

On the Innervation of the Liver.—Dr. Pal, working in the laboratory of Professor Stricker, read a paper on the innervation of the liver. Since the discovery of the "piqûre" by Claude Bernard, there was a hypothesis in physiology which stated that there existed special hepatic nerves which took their course along the sympathetic nerve. Several authors had also repeatedly claimed the existence of "vaso-dilators" and "vaso-constrictors" for the liver. No exact evidence of the correctness of these statements had, however, been furnished, and, according to the opinions of Heidenhain, the blood-current in the liver chiefly depended on the condition of innervation of the portal vein, and, on the other hand, on the conditions of blood-pressure in the inferior vena cava. In order to elucidate the question as to the innervation of the hepatic blood-vessels, all the different vessels had to be ligatured. Dr. Pal had eliminated from the circulatory system all those blood-vessels which were supplied by the splanchnic nerve, by ligaturing the thoracic part of the aorta, the inferior vena cava above the entrance of the renal veins, and finally the portal vein. All the blood-vessels which conveyed blood to the liver were thus closed, whereas those which carried off the hepatic blood were allowed to remain open. The peripheral stumps of the splanchnic nerve were then irritated, and a considerable increase of the blood-pressure was obtained, which was first looked upon as being due to the liver alone. There were now performed controlling experiments in such a way that the inferior vena cava was ligatured opposite the entrance of the hepatic veins, and the peripheral stumps of the splanchnic nerve were irritated. An increase of blood-pressure was also obtained on this occasion, but it was inferior to that obtained when the hepatic veins were allowed to remain open. It resulted from these experiments that the liver pressed out blood during the irritation of the splanchnic nerve. To make this statement quite sure, Dr. Pal, in part, availed himself of the method devised by him and Ikalowicz, and, in part, that of Claude Bernard, viz., he introduced, through the external jugular a catheter into one of the hepatic veins or into the inferior vena cava, as far as the diaphragm, and applied ligatures around the aorta, the cava (below the entrance of the hepatic veins), and portal veins; the splanchnic nerves were irritated. An increased discharge of blood from the hepatic veins was thus caused. It therefore became evident from these experiments that the splanchnic nerve exerted a direct influence on the liver, or, in other words, that it contained hepatic nerve-fibres.—*Medical Press.*

The Treatment of Pulmonary Phthisis by Parenchymatous Injections of Creasote.—Dr. Leo Rosenbusch, of Lemberg, publishes in the *Przeglad Lekarski*, Nos. 5 and 6, 1888, the report of a series of cases of phthisis treated by parenchymatous injections of creasote. His method consists of injections of a solution of three per cent. creasote in almond-oil into the affected places of the lungs. The injections are to be made by means of the Pravaz syringe, with a needle 6 to 8 ctm. long, every second or third day, one-half syringeful being injected into each apex. The injections should be made very slowly, and the patient must not breathe deeply, and after it must lie still for a few minutes. After the injections, the writer states, the cough becomes less violent, and in from five to eight hours the temperature falls and remains normal for a period of ten or twelve hours. Sometimes directly after the injections the temperature rises for a short time, but afterward it falls to the normal. The quantity of sputum diminishes considerably, dyspnœa disappears, and the perspirations cease. The general condition of the patients is bettered, and an improvement is also noted in the physical signs. Creasote employed for injections should be of vegetable origin, and must be distinguished from mineral creasote, from which it differs in every respect.

Addison's Disease.—Dr. J. Parvinski reports in the *Gazeta Lekarska*, of Warsaw, Nos. 4 and 5, 1888, a case of Addison's disease observed by him in which the diagnosis was confirmed by post-mortem and microscopical examination. The author believes that the dark pigmentation of the skin is the result of either functional or somatic changes in the abdominal plexuses of the sympathetic nerve, and he bases this view upon the following: 1. The anatomical structure of the suprarenal capsules, which contain a net-work of nerves, starting from the cœliac and semilunar plexuses, the vagus, and the phrenic nerves. Besides this the medullary substance contains even nerve-cells. 2. The suprarenal capsules are most frequently the seat of anatomical changes in patients dead of Addison's disease. 3. These pathological changes, characteristic of Addison's disease, affect most frequently the medullary substance of the suprarenal capsules, that is to say, the part which is most richly supplied with nerves. 4. The nearness of the cœliac and semilunar plexuses to the suprarenal capsules.

The Rôle of Bile in the Digestion of Fat.—Dr. Dastre, in a recent report to the Société de Biologie of Paris, said that he had previously proven that the presence of bile in the stomach during different periods of digestion did not take from the gastric juice its digestive power. Consequently, it could not be the cause of vomiting or of severe gastric troubles. At the present time, owing to the success of two operations for cholecysto-intestinal fistula, he thought himself in a position to conclude that the bile contributed as well as the pancreatic juice to the digestion of the fats, an opinion which is counter to that expressed by Claude Bernard. In fact, the two animals being in good condition four months after the establishment of the fistula, they had been given a meal of fat and milk, and then slaughtered during full digestion. The examination showed with absolute clearness that the lacteals were transparent between the stomach and fistula, and, on the contrary, entirely white and milky below the fistula; that is to say, where the bile had been able to get. Consequently, if observation on the rabbit shows us that the bile alone is unable to emulsify the fats, the preceding experience shows us that the pancreatic juice alone is also powerless. They must be mingled, in order to act well. In other words, bile, as well as the pancreatic juice, takes part in the digestion of fats. —*Le Progrès Médical.*

The Varieties of Aconitine and the Dangers of their Medical Use.—At a late meeting of the West London Medico-chirurgical Society, Dr. Thudichum read a paper on this subject (*The Lancet*). He said that often drugs possessing healing properties have powers going far beyond. On account of progressive concentration alarming effects may be produced and a medicine become discredited. The different varieties of aconitine are due to its varying sources and differences in soil and climate. One variety is actually four thousand times more poisonous than another. Even the so-called "English" aconitine is not always the same substance; one manufacturer may prepare it from A. napellus, another from A. ferox. The German aconitines are also of different strengths, and the French "aconitine crystallisée" is really a nitrate. With such variations, it is surprising that fatal mistakes have not more often ensued. The author has compared the chemical properties of a large number of specimens of aconitine; there are certainly three distinct substances known by the name, and very likely a fourth. They vary in their chemical reactions, as well as in their poisonous power. On account of the danger of their use, he agrees with Professor Gluch that they should all be removed from the Pharmacopœia. He considers that with aconitine, paralysis of the sensory nerves is very slight and superficial, and that the motor nerves are more affected. He alluded to numerous experiments on rabbits, and especially remarked on the rapidity of the poisonous effects. In his opinion, the best treatment after a poisonous dose is the swallowing of charcoal and an emetic of sulphate of zinc.

Sour Milk and Buttermilk in the Nutrition of Invalids and Others.—Dr. Demuth advocates the use of sour-milk and buttermilk as cheap, effective, and easily assimilable nutritive agents. Both are easily digested, on account of the finely divided condition of the caseine and the presence of acids. He also says that buttermilk is useful in all cases where a milk cure is indicated, and is particularly to be recommended in consumption. Sour milk has shown itself to be very beneficial in scrofulosis, neurasthenia, hypochondriasis, in convalescence, in diseases of the organs of respiration and deglutition, chronic catarrh of the air-passages, nervous disturbances following excessive or exclusive meat diet, dropsy, albuminuria, and Bright's disease. It is also useful in diabetes mellitus. Both forms of milk are efficacious in chronic metallic poisoning and inflammatory and febrile conditions, especially in typhoid fever. They are not to be used in ulcerous processes in the alimentary canal, a fact not always considered in ulcer of the stomach, ulcerating cancer, and tuberculous ulceration of the intestines.—*Vereinsblatt für Aerzte.*

Notes on the Vegetable Globulins.—Vegetable globulins are divided by Martin into two classes, vegetable myosins and vegetable paraglobulins. The myosins are soluble in ten to fifteen per cent. sodic chloride solutions, from which they are precipitable by saturation with sodium chloride or magnesic sulphate; they are soluble also in ten per cent. magnesic sulphate solution, this giving a coagulum at 55° to 60° C. The paraglobulins are soluble in saline solutions, and are precipitated from these solutions by saturation with sodium chloride or magnesic sulphate. In a ten per cent. solution of the latter they coagulate between 70° and 75° C. If precipitated from their saline solutions by dialysis, unlike the myosins, they are still soluble in ten to fifteen per cent. solutions of sodium chloride and magnesic sulphate, and are not transformed into albuminates. In an acid solution in the presence of sodium chloride, hydrogen peroxide rapidly changes albumen into a proteid insoluble in water, a temperature of 37° to 40° C. accelerating the process. If the hydric peroxide solution be well shaken up with an equal quantity of white of egg, and about fifteen grains lactic acid and fifteen to thirty grains sodium chloride added, a clear mixture will be obtained, which becomes cloudy if held in the hand, and sets into a firm, cheesy mass if placed in an incubator for twelve hours. The precipitate is soluble in sodic-carbonate solutions, and can likewise be readily peptonized by artificial gastric juice. It belongs more to the nature of acid albumens than caseine, and is stated to be a mixture of gelatinous acid albumens, with a large quantity of a caseine-like proteid. Lactic acid, sodium chloride, and hydric peroxide, are all present in sweat, as also in certain of the tissues; it therefore becomes a question whether the deep cutaneous tissues may not be able to coagulate the proteids circulating in the lymph; and also whether the coagulation of blood and muscle, and the formation of caseine in milk, may not receive a similar explanation.

For the Relief of Pelvic Pain there is no remedy equal to cocaine; and its application is simple. After the vagina has been thoroughly cleansed with the antiseptic spray, it becomes a good absorbing surface, and is then sprayed with a four per cent. solution of cocaine directed mostly against the cervix, and a soft unabsorbent cotton tampon, with string attached, either plain or rolled in pulverized boric acid, placed in the vagina, to aid the retention of the solution. This forms an elastic support for the uterus, which is so often needed. Its action is not merely local in the vagina, but it is absorbed by the clean surface, and takes effect upon the whole capillary circulation of the pelvis. One application of this kind will usually relieve all the pain and soreness in simple troubles, and the patient will return with a smile at her next visit, and say that she feels like a new woman. Repeated applications, at intervals of two days, will cure well-marked cases of pelvic congestion and inflammation in a remarkably short time by relieving the capillary engorgement.—Dr. A. H. Goelet in *Annals of Gynecology.*

Nitroglycerine in Tinnitus Aurium.—Lautenbach has found nitroglycerine useful for the relief of ringing in the ears, associated with functional or organic heart disease, but not due to serious ear trouble. Marked benefit was usually obtained within a day or two, although occasionally the remedy was continued for two or three months before much improvement was noted.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 2, 1888.

HUTCHINSON ON THE ABORTIVE TREATMENT OF SYPHILIS.

IN a recent address on this subject, Dr. Jonathan Hutchinson (*The British Medical Journal*) informs us that for many years past he has been in the habit of assuring patients who came to him with indurated chancre, but without any other symptoms, that they would in all probability wholly escape the secondary stage. As the result of increasing experience, he now holds out this hope with more confidence than ever.

The best treatment of syphilis is of unquestioned importance, and so eminent an authority as Hutchinson is certainly entitled to a full hearing, even if his views are at variance with those held by others of equal prominence with himself. The author's doctrine is clearly opposed to the most recent teachings of the German and French schools.

This is what he says: "My treatment has been almost uniform, and has consisted in giving mercury in the form of gray powder in one-grain doses three times a day, at least, and more frequently if the symptoms did not quickly yield. I have always told the patient that he must take these pills for six months at least. The results have also been very uniform, or have varied chiefly according to the period of the disease at which the treatment was begun. The effect of the medicine in softening the induration is usually quite evident within a week, and may be expected to be complete in the course of a month or a little more. After this the patient remains without symptoms till the end of the course, except, perhaps, some slight persisting enlargement of the inguinal glands. At the end of the six months, if the treatment is left off, there not very infrequently follows in three weeks or a month an erythematous general eruption. This eruption is never severe, never becomes papular or scaly, and always vanishes in a few days if the mercury is resumed. It is never attended by failure of health, and but rarely by sore throat. On account of its frequency after six months' courses, I have lately been in the habit of continuing the treatment for nine or twelve months, and am willing to admit that it might be wise to continue it for still longer periods. As regards relapses at still longer periods, I must state that, in a certain proportion of cases, sores in the mouth or scaly patches in the palms, or a liability to transitory erythemata on the skin have occurred, but they have generally been in connection with some special kind of irritation."

Hutchinson maintains that it is quite possible, by the early and continuous use of mercury, to suppress the secondary stage—in other words, to make it abortive. In exceedingly few cases where it has been possible to use mercury without interruption in this way has he known a well-characterized secondary eruption or a typical sore throat to occur. In cases where diarrhœa or sudden ptyalism has caused the course to be interrupted, the success has been less complete. But where the patient is careful, and can bear the drug, he believes that it is easily possible to prevent secondary symptoms. This assertion is not by any means the same as saying that it is possible to cure syphilis, for it does not concern itself with the tertiary stage.

In concluding his instructive remarks, Hutchinson emphasizes the points which he has made, as follows: "The early use of mercury does not only greatly shorten the duration of the primary phenomena, but it also much modifies, and in many instances entirely prevents, those of the secondary one. When circumstances favor the febrile stage of the exanthem, syphilis may be rendered wholly abortive. If we can accept this proposition, we shall have gained a step in the orderliness of our future work, and in reference to this the following problems seem to lie before us.

"What plan of treatment is most successful in suppressing the febrile or secondary stage?

"Does the suppressing of this stage tend to prevent what are called reminders, or those minor, and for the most part local, symptoms which often intervene between the febrile stage and tertiary phenomena?

"Are those in whom the febrile stage has been aborted by artificial means more or less than others liable to tertiary phenomena?

"Is it possible, by anticipatory treatment, to prevent or abort the phenomena of the primary stage; and, if this be done, what is the influence upon the further course of the disease?"

It will remain for the accumulating experience of the entire profession to give decisive answers to this series of suggestive questions.

NEPHRORRHAPHY FOR FIXATION OF FLOATING KIDNEY.

IF the evidence of modern writers is entirely trustworthy, floating kidney is not as infrequent a condition as has been formerly supposed. Very annoying symptoms are often the result of this morbid state. The attempt to afford symptomatic relief by suitable bandaging is not always crowned with success. And not every person afflicted in this way can muster sufficient courage to submit to the operation of nephrectomy, which surgical pioneers rarely hesitate to advise. Hence any milder measure which affords some chance of cure is to be considered a chirurgical desideratum. The operation known as nephrorrhaphy appears to come under this head. First successfully performed by a German surgeon, named Hahn, it has already found quite a number of imitators and advocates. The operation consists merely in cutting down upon the kidney, and then stitching it to the edges of the wound, and expecting it to stay fixed there.

In our country we have heard but little of this simple little manœuvre. A case has recently been reported, however, by Dr. Wilcox, of Buffalo. It is published in the *Annals of Surgery*, and bears transcription here:

"Sarah W——, aged twenty-four. About nine years ago, while lifting heavily, felt something 'give way in her back.' A few weeks after, she detected a distinct tumor in the abdomen, a little to the right and on a level with the umbilicus. She suffered but little pain, but was worried over its presence. She consulted a number of physicians in England, where she was then living, but gained no satisfactory information regarding her trouble.

"As time went on she began having pains in the 'tumor' and a heavy dragging sensation. There were no urinary symptoms; in fact, the foregoing history was about all the subjective symptoms that could be elicited.

"Upon examination the tumor was found to be somewhat larger than an ordinary-sized kidney, was quite freely movable, and could be crowded up to the under edge of the liver or pushed down to the iliac region, and even on to the left side; it was somewhat painful if squeezed. It was with some difficulty forced back into its normal position. The diagnosis of floating kidney was rendered.

"An operation for fixation of the displaced kidney having been determined on, the patient was anæsthetized and turned well on her sound side. The skin was shaved and scrubbed with bichloride solution. A free incision was then made midway between the last rib and the crest of the ilium, extending from the anterior edge of the quadratus lumborum forward for about four inches. After controlling all hemorrhage, the incision was continued through the entire wall, the hand inserted, and the kidney grasped and brought out to the lips of the wound. Here it was held with some difficulty, as so long a time had elapsed since it had been in its natural place that it required some stretching of the tunica adiposa to retain it. After bringing it to the opening, examining its surface, and demonstrating its blood-vessels, there was left no doubt as to its being a kidney. A heavy catgut suture was passed through the perirenal fat and each lip of the incision; this was repeated three times, till the gland was securely anchored to the wound.

"The remaining portion of the incision was loosely drawn together and allowed to heal by granulation. It was dressed with the usual antiseptic precautions, and the patient put to bed.

"She made an excellent recovery, the temperature at no time going above 101⅕° F. She is now able to walk quite a distance and do ordinary light work. The gland has kept its position, and there is no pain or dragging."

This is certainly a gratifying and encouraging result, and should induce others to imitate this simple procedure before resorting to so grave an operation as nephrectomy.

WEAR AND TEAR OF THE MEDICAL PROFESSION.

At the April meeting of the State Board of Health of Illinois, Dr. John H. Rauch presented a report upon the mortality-rate and causes of death among physicians. The paper contains many facts of interest.

Dr. Rauch's observations are based upon data accumulated in the past ten years regarding Illinois physicians. He finds that the average duration of life among them is lower than is usually supposed to be the case among physicians, viz., fifty-two years, and that only eleven out of every one hundred reach the scriptural limit of threescore years and ten. During the past ten years there have been about six thousand physicians living annually in the State, among whom there were annually about eighty deaths, giving an annual death-rate of 13.3 per thousand, which is certainly quite high.

A table is given which we append, showing the yearly death-rates, per thousand, of physicians in Illinois, of all males in Illinois, and of both sexes in the United States, at grouped ages:

Ages.	Yearly Death rate per 1,000.		
	Physicians.	All Males.	Both Sexes.
24-30	6.4	6.6	9.7
30-40	7.4	7.6	11.9
40-50	11.5	10.3	13.9
50-60	19.5	16.5	18.1
60-70	31.1	32.0	23.8
70-80	53.0	64.4	46.9
Over 80	476.1	126.0	113.3

This shows that the death-rate among physicians in the early part of their practice is lower than that among males generally, or even in the general population. After the age of forty, however, the death-rate is proportionately greater, and after the age of sixty it is higher than in the general population. The doctor, after he gets to be forty, therefore, should be more than ordinarily careful, for his chances of life are less than those of his neighbor.

With regard to the causes of death Dr. Rauch gives tabulated statistics, and adds: "Of the grouped causes of death, consumption, diseases of the respiratory organs (including ninety-one from pneumonia), and Bright's disease, caused two hundred and sixty-eight deaths, or more than one-fourth of the total. If to these be added a share of the deaths from diseases of the heart—the sequelæ of rheumatism—a fair estimate may be made of the effect of exposure to the vicissitudes of weather upon the wear and tear of medical life. As a result of mental strain and anxiety; of insufficient, irregular, and interrupted sleep, and similar causes is the total of deaths from diseases of the brain and nervous system, embracing forty-three from various forms of paralysis. In the group of zymotic diseases (enteric fever given separately) there were five deaths from diphtheria, one each from small-pox and yellow fever, and eight from traumatic infection (septicæmia, etc.), all contracted from attendance upon patients.

"Less creditable to the *morale* of the profession are the eighteen deaths from overdoses of opiates and narcotics, the seven admitted suicides, and the deaths from alcoholism, direct and indirect—twelve of the former and at least eight of the latter. There is this to be said, however, in this connection—that the proportion of mortality from these causes is steadily diminishing."

EXPERIMENTAL INVESTIGATIONS OF TUBERCULOSIS.

Dr. Cornet, of Berlin, has been for two years investigating certain problems in the pathology and therapy of tuberculosis at the Hygienic Institute, over which Professor Koch presides.

A brief preliminary account of his results, which cover three different lines of inquiry, is given in a recent issue of the *Internationale klinische Rundschau.*

The first series of investigations takes up the subject of the presence of the tubercle bacillus outside the human body, or, in other words, a study of infected localities. The method employed was to rub down a supposed infected surface with a sterilized sponge, the dust and dirt collected was put in sterilized bouillon, and then injected into healthy guinea-pigs with proper precautions. Working as he did under Koch, it is safe to admit that Dr. Cornet's methods and technique were trustworthy. The injected animals were killed in about forty days after the inoculation, since within that time only the abdominal viscera can become infected.

In twenty-one wards of different Berlin hospitals, which were exclusively or in part occupied with phthisical patients, the walls at the head of the beds were treated in the way described. Fifteen of these wards were shown to contain infective tubercle bacilli. Of 94 animals injected, 53 died of intercurrent diseases; of the remainder, 20 were tuberculous, 22 healthy.

As phthisis often develops among the insane, the wards of two asylums were investigated, and bacilli were found at least once in each one of them.

Two prison-cells were tested, with negative results.

The dwellings of 53 phthisical patients were examined. In only 42 of the cases could the tests be used, and from these it was shown that nearly half of the houses contained infective dust.

Tests were made in two dispensaries, one inhalation-ward for chest diseases, one room containing two lupus patients, an orphan asylum with many scrofulous children, the audience-room of the Pathological Institute, all with negative results.

Nothing was found in several surgical wards, or in three much-frequented streets in Berlin.

On the other hand, active tubercle bacilli were found in a Berlin hotel, in which a phthisical patient had been living; also in a room in which, six weeks before, a woman had died of phthisis.

A most important observation was made, to the effect that *in no single instance in which the sputa were carefully disinfected* was there evidence of bacilli in the apartment.

The second part of Cornet's work is chiefly confirmatory of the observation of Koch that the infecting bacilli enter by way of the lymphatics. In inhalation-tuberculosis the bronchial glands are first affected; in abdominal tuberculosis the mesenteric glands.

In the third part of his investigation Cornet takes up the therapeutical phase of the subject. His method, which is not a new one, was to give animals certain drugs and then make inoculations of tubercle bacilli, watching to see if the tissues would be so modified by the internal medication as to retard or prevent the tuberculosis. The animals used were guinea-pigs and rabbits. The first experiments were with tannin, which was given in amount equal to about two ounces, for a man weighing one hundred and twenty-five pounds. The animals became tuberculous in twenty to thirty-four days. Other animals were given acetate of lead, pinguin, sulphuretted hydrogen water, menthol, corrosive sublimate, creolin, and creasote. They all died of tuberculosis within twenty to ninety days. Twelve animals were infected with tuberculosis; six of them were sent to Davos, six kept in the cages at the Hygienic Institute. They all died of phthisis, and in about the same time.

These experiments were, therefore, entirely negative. They appear to show that the living body cannot be medicated so as in any way to modify the progress of tubercular disease.

It is not quite legitimate, however, to draw definite inferences from guinea-pigs and rabbits, animals which are more sensitive to tuberculous infection than man.

News of the Week.

The Thirty-third Annual Meeting of the Kentucky State Medical Society will be held at Crab Orchard Springs, commencing Wednesday, July 11th.

The Ohio State Medical Society holds its forty-third annual meeting at Columbus, O., on June 13, 14, and 15, 1888.

The Forty-Second Annual Meeting of the State Medical Society of Wisconsin will be held in the Council Chamber, in the Court House of the City of Milwaukee, the session commencing Tuesday, June 5, 1888.

The New Jersey State Medical Society meets at Schooley's Mountain on June 12 and 13, 1888.

A Medical College in Kansas.—There is talk of organizing a medical college at Topeka, in connection with the University of Kansas. The peculiarity of Kansas doctors just now, says one of them, is that they do not propagate their species—they have no machine for manufacturing pure-bred Kansas doctors. Furthermore, we are told that Kansas doctors do not want such a machine, unless it is amply endowed by the State and made independent of students' fees.

The Southern California Medical College held its Annual Commencement at Los Angeles, on April 11th, and conferred degrees upon a class of nine. The Southern California College is devoted to the promotion of medicine and also of matrimony—three of the graduates being married shortly after they had received their diplomas.

The Patent on Antipyrine is, we are informed, a patent or copyright of the name only. The drug itself can be manufactured and sold under another name, and it is proposed in Paris to do this. Antipyrine will be made and sold as "Analgesine," or Dimethyloxyquinizine.

Dr. Jacob D. Conover, who for the past fifteen years had been employed by the health department as a sanitary inspector in the division of contagious diseases, died on May 28th, at his country home in Morristown, N. J. He was an able assistant to Dr. Cyrus Edson, who is in charge of the division. He had been in poor health for eight years, from disease contracted in the service of the department, and for eleven years the Doctor was engaged in vaccinating the pupils in the public schools. During that period 128,500 children were vaccinated by him.

Personal Nomenclature in Disease.—*Physician* (after a consultation): "I congratulate you sincerely."

Patient (smiling): "Am I recovering?"

Physician: "Not exactly that; but on consultation we find that your case is entirely unique, and we have decided to give your name to the disease, if our diagnosis is confirmed at the autopsy."—*Journal de Médicine*

Professor von Bergmann and Sir Morell Mackenzie.—At a meeting of the Berlin Medical Society on May 2d, Professor von Bergmann took occasion to refer to some comments upon his action in withdrawing from the Emperor's case, made by the Berlin correspondent of the *British Medical Journal.* The correspondent intimated that von Bergmann at least inspired some of the attacks publicly made upon Mackenzie and Hovell, and that as von Bergmann had not contradicted the intimations of this kind they might be accepted as true. Professor von Bergmann said at the meeting in question, that he "was silent not because he was wrong, but because he as well as every honorable British or German physician could not speak publicly of matters pertaining to the sick-bed of his patient." This was a slap at Mackenzie, and perhaps a justification of himself, though it is hard to see why he could not at least deny accusations of ungenerous conduct toward his colleagues.

Professor von Bergmann's insinuations regarding Sir Morell Mackenzie, referred to above, are replied to by the latter in a letter to the *British Medical Journal* of May 12th. Dr. Mackenzie shows quite plainly that von Bergmann must have inspired some of the attacks made by the German press upon the English physicians. He says: "I have never given any information to the press except such as was permitted by august personages, with a view of contradicting the false and exaggerated reports which certain people have delighted to spread. Whilst, however, Professor von Bergmann was in attendance, the minutest details from the sick chamber were published in the *National Zeitung*, a paper which received its information from Professor von Bergmann. Not only was the state of the pulse given, but the frequency of the respiration was published; not only was the exact food and drink stated, but the medicine, and *even the surgical measures proposed by Professor von Bergmann*, but not carried into effect, were described. Neither I nor my English colleague have ever given any information as to food or medicine, much less as to the frequency of respiration. Any details on such matters published in English papers have been taken from German sources." While Sir Morell is making out a very good case for himself, he is, nevertheless, we believe, making his first mistake in bringing his personal quarrels before the public.

Dr. William J. Moore, Norfolk's oldest physician, and one of the most respected citizens, died at his residence in that city on May 19th.

Preliminary Programme of the Fifth Annual Meeting of the American Climatological Association, to be held in Washington, D. C., September 18, 19, and 20, 1888, in connection with the Congress of American Physicians and Surgeons.—The first session will be held Tuesday, September 18th, at 2 P.M.; following which, there will be morning and afternoon sessions on Wednesday and Thursday. The President has appointed Drs. F. H. Bosworth, of New York, and E. C. Morgan, of Washington, a committee to provide a banquet to be held Wednesday evening, to which all the members intending to be at the meeting are invited to subscribe. The following papers and discussions have been arranged for, and others may be added to the list: The President's Address, Dr. A. L. Loomis, New York; "The Relation of High Altitudes to Germ Disease," Dr. S. A. Fisk, Colorado; "Is Climate an Etiological Factor in Graves' Disease," Dr. R. G. Curtin, Philadelphia, Pa.; "An Environment Experiment Reported," Dr. E. L. Trudeau, Saranac Lake, N. Y.; "Definite Results Obtained by the Climatic Treatment of Disease," Dr. A. Y. P. Garnett, Washington; "Invalids Suited for Treatment at Colorado Springs," Dr. S. E. Solly, Colorado; "Influence of Semi-Tropical Latitudes on Types of Disease," Dr. John Guiteras, Charleston, S. C. *Discussion:* "The Relative Importance of Different Climatic Elements in the Treatment of Phthisis," Referee, Dr. E. T. Bruen, Philadelphia, Pa., Co-Referee, Dr. V. Y. Bowditch, Boston, Mass.; "Observations on the Use of Terebine," Dr. D. M. Cammann, New York; "Climate and Bright's Disease," Dr. J. C. Wilson, Philadelphia, Pa. *Discussion:* "The Mineral Waters of the United States; Therapeutic Value as Suggested by their Chemical Composition," Dr. A. C. Peale, Washington, D. C.; "Their Therapeutic Value in Gastro-Hepatic Diseases," Dr. William Pepper, Philadelphia, Pa.; "Their Therapeutic Value in Urinary and Arthritic Diseases," Dr. A. H. Smith, New York; "Their Therapeutic Value in Malarial Diseases," Dr. J. C. Van Bibber, Baltimore, Md.; "Report on Mineral Springs," Dr. C. C. Rice, Chairman, New York; "Interpleural Pathological Products; their Cause, Significance, and Special Relationship to Pulmonary Phthisis," Dr. J. R. Leaming, New York; "Conditions which Tend to Render the Atmosphere of a Locality Aseptic, J. T. Whittaker, Cincinnati, O. *Discussion:* "Influence of Altitude on Cardiac and Pulmonary Diseases," Referee, Dr. F. Donaldson, Sr., Baltimore, Md., Co-Referee, Dr. J. J. Levick, Philadelphia, Pa.; "Climatic Characteristics of Texas," Dr. Morse K. Taylor, U. S. A., San Antonio, Tex.; "Therapeutic Differences of Mountain and Sea Air," Dr. W. H. Geddings, Aiken, S. C.; "Indications and Contra-indications for Altitude in Treatment of Phthisis," Dr. F. I. Knight, Boston, Mass. *Discussion:* "Nasal and Neurotic Factors in Etiology of Asthma," Referee, Dr. F. H. Bosworth, New York, Co-Referee, Dr. E. L. Shurly, Detroit, Mich.; "Therapy of Climate," Dr. I. H. Platt, Lakewood; "Therapy of Ocean Climate," Dr. A. L. Gihon, U. S. N.; "Climatic Characteristics of Roan Mountain, Eastern Tennessee," C. J. Kenworthy, Florida; "Notes of Summer in Switzerland," Dr. D. B. St. John Roosa, New York; "An Epidemic of Cerebro-Spinal Meningitis in Central New York," Dr. W. T. Ford, Utica, N. Y.; "Further Contribution to the Study of Consumption among the Indians," Dr. W. Matthews, U. S. A.

A. L. Loomis, M.D., LL.D., *President.*

J. B. Walker, M.D., *Secretary.*

Dr. John R. Conway died at his residence in this city on May 24th. He was born in New York October 21, 1825, graduated at the College of Physicians and Surgeons in 1847, and has since practised in this city, succeeding his father, Dr. Edward Conway.

The Extraordinary Increase of the Medical School in Edinburgh within the past twenty-five years has attracted general attention. In 1861–62 the medical students numbered 543, in 1886–87 they numbered 1,872.

England's leading Woman Doctor is said to be Mrs. Garrett Anderson, who has a practice worth $50,000.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Thirty-ninth Annual Meeting, held in Cincinnati, O., May 8, 9, 10, and 11, 1888.

SECTION ON DISEASES OF CHILDREN.

F. E. Waxham, M.D., Chairman.

The discussion of the subject of

INFANT FEEDING

was opened by **Dr. C. W. Earle**, of Chicago, who began his paper with a résumé of Baginsky's last work, in which he attributes the great mortality among infants largely to their deprivation of mother's milk. When for any reason the child cannot be suckled by its mother or a wet-nurse, the basis of its food must be cow's milk. This is more liable to fermentation than is human milk, and must be sterilized by boiling before it is fed to the infant. In the case of premature children, when the mother's milk cannot be obtained, the speaker preferred a mixture of cream with barley-water or lime-water, to which milk-sugar is added. Later he used condensed milk. But there should be no routine practice for all cases, for a food which agreed with one child might cause digestive disturbances in another. He classified foods into young and old, according as they were best adapted for younger or older children. In the first class he included cream mixtures and malted milk; in the second, the Liebig foods and the starchy foods. The index of good nutrition is the growth of the child. It is objected to most of the prepared milk foods that they contain starch and that the casein of the milk is unchanged, yet in practice they are seen to act well. One cause of failure in the use of condensed milk is that it is often given in too great dilution. Peptonized milk disagrees with many babies, and foods prepared with pancreatine are theoretically objectionable, and practically are often unsatisfactory. The objection to starch in many of the prepared foods was, he thought, in great measure purely theoretical, for, as a matter of fact,

YOUNG CHILDREN DO DIGEST STARCHES.

Such foods are, however, of special value in the case of older children.

Dr. W. B. Atkinson, of Philadelphia, read the second paper, entitled

THE INFANT-FOOD PROBLEM.

The question of infant feeding was, he contended, one of great public importance, calling for the attention of legislators, for the weakly child becomes the sickly man. He thought that cow's milk was the best substitute for human milk, but the notion of one cow's milk being the best was erroneous, for the mixed milk of the whole herd was much more likely to be uniform and was less liable to contamination from accidental causes. The milk should be partially peptonized and diluted with water, and to the mixture a carbohydrate should be added. For this purpose he preferred dextrine, as this substance does not undergo fermentation and yet can be readily digested by the infant. The speaker preferred evaporated milk to condensed milk, as the process of condensation was, in this, not carried to such an extent. If dry milk solids were to be used, as advocated by Vaughn, they should be partially peptonized, and some dextrine should be added. A point of great importance was the thorough sterilization of all water added to the milk for infant use.

Dr. W. S. Christopher, of Cincinnati, had found condensed milk very serviceable during the first month or six weeks of life, but after this it caused flatulence and other digestive disturbances. He had not been pleased with the action of peptonized milk, which almost always caused diarrhœa. This was to be explained by the fact that the peptonizing ferment is trypsin, which renders the proteid compounds peculiarly suitable for the nourishment of micro-organisms, and all pancreatic digestion-mixtures are found quickly to swarm with bacteria. This does not so readily follow upon gastric peptonization. He regarded the absence of pancreatic secretion in the young infant as highly protective, and thought the addition of a pancreatic ferment to infant foods was therefore unphysiological. Infants ordinarily digest starches with ease, notwithstanding the popular notion to the contrary. The explanation of this is to be found in the fact that nearly every fluid in the body possesses amylolytic properties, and is therefore capable of digesting at least a limited amount of starch. He did not agree with the previous speakers who had maintained that dextrine is not fermentable. Dextrine is transformed into sugar, during digestion, and the latter is readily changed to lactic acid if the proper micro-organisms be present. He did not think the efforts made to imitate human milk were altogether in the right direction. Human milk, if it could be bought in open market like cow's milk, would in all probability give no better results than the latter. It would have to be given by the bottle, and the same septic influences would be at work as in the case of other foods. Two forms of abnormal fermentation may be recognized clinically: an acid fermentation, maintained by carbohydrates, and a putrid fermentation, maintained by the proteids. The diagnosis of these two forms of fermentation can be readily made by an examination of the stools. In cases of abnormal intestinal fermentation, occurring in infants at the breast, the speaker did not hesitate to wean at once, and to put the child on a suitable artificial food. For the proper handling of these cases the physician must have two foods; one a carbohydrate, to be fed during putrid fermentation, and the other a proteid, to be fed during acid fermentation, while both are to be given when the bowels are in a healthy condition.

Dr. I. N. Love, of St. Louis, said that in infants there was a natural tendency to impairment of the secretions, producing a further tendency to intestinal diseases. To correct this condition he was in the habit of giving calomel in small doses, as this agent not only stimulated secretion of the digestive fluids, but also prevented fermentation. He was by no means ready to insist upon the employment of a wet-nurse, for the moral objections against these individuals very often counterbalanced their usefulness. He had obtained the best results with peptonized milk, but always used the greatest care in its preparation, frequently attending to this himself. Condensed milk was good only for temporary use, and had a bad effect, when long continued, upon the child later in life, leaving it poorly fitted to combat subsequent disease. In infant feeding no point is too insignificant to deserve the closest attention. A change of food is often desirable. The speaker was in favor of frequent bathing, more for the absorption of water than for cleanliness. After bathing he favored rubbing the child with peptonized oil.

Dr. G. W. Jones, of Danville, Ill., had had a large experience in the management of bottle-fed babies, and he never hesitated, when occasion demanded, to take a child away from its mother and put it on the bottle. He was in favor of a change of diet from time to time. When the child was at the breast this change was effected by modifying the diet of the mother, but in bottle-fed infants it was an excellent plan to give some other and chemically different food after one had been taken for a time. It was of prime importance to boil the food thoroughly in order to sterilize it.

Dr. J. A. Larrabee, of Louisville, agreed with previous speakers that the mother's milk was not always best for the child. When a child has colic after nursing, this may often be prevented by giving it a diluent, such as barley-water, before it takes the breast. Testing the nutrition by the scales was not always reliable. Rachitic babies often grew fat and increased in weight, yet it could not be said that their nutrition was of the best. He believed some salt was necessary in all foods, and preferred the phosphate of soda. Dextrine, arrow-root, and barley-water were useful in effecting mechanical division of the foods employed.

Dr. D. A. K. Steele, of Chicago, read a paper on the

SURGICAL TREATMENT OF EMPYEMA,

of which the following were the conclusions:

1. The surgical treatment of empyema in children is eminently satisfactory and yields better results than in adults.
2. Multiple hypodermic aspiration is necessary to perfect a diagnosis, and should always be resorted to in cases of thoracic disease about which there is any element of doubt, especially in cases of pneumonia that continue beyond the usual period.
3. Aspiration cures a small minority of cases and should always precede a more radical operation, especially in localized empyemas.
4. Free incision and drainage, with local anæsthesia, under strict antiseptic precautions, gives the most satisfactory results in the majority of cases.
5. Subperiosteal resection of the rib is sometimes necessary to allow of perfect drainage.
6. Thoracoplasty is rarely required in children.
7. Other methods of treatment should be resorted to for special cases or circumstances.
8. Early incision, perfect drainage, and complete antisepsis should be the rule.

Dr. A. Y. P. Garnett, of Washington, remarked that in children empyemas are of recent origin, and therefore not complicated by the changes induced by long-continued inflammation, and hence afford a suitable field for the simpler operations. He favored the use of a large trocar and drainage-tube.

Dr. Begg, of Ohio, said that he had resected the rib in his first case, and regretted it afterward. He now used the trocar, aspirating subsequently in another place. He had treated three cases in this manner successfully.

Dr. M. P. Hatfield, of Chicago, presented a communication entitled

HEPATIC INCOMPETENCE IN CHILDREN.

Attention was called to the affection frequently found in children, more often in girls, characterized by sallow skin, anorexia, dyspepsia, and constipation, together with various neuroses. This group of symptoms was frequently confounded with malaria, but it was only aggravated by the use of quinine and iron. Sometimes it was called biliousness, a term of very indefinite meaning. The essayist proposed the term "hepatic incompetence," grouping under it all conditions resulting from a failure of the liver to perform any of its peculiar functions. He divided these into three classes: 1. Bilious, in which there is a diminution or loss of the normal amount of bile-pigments in the intestinal canal. 2. Lithic, a group of symptoms described by many writers under the term lithæmia, in which there is a failure on the part of the liver to transform albuminoids into urea. 3. Toxæmic, in which the liver fails to destroy the toxic substances (leucomaïnes) normally formed within the body.

Treatment should be largely dietetic, the diet-list containing starches, fruits, and broths, while the heavier animal foods are to be interdicted. Salicylic acid and compound spirits of lavender act well in the cases characterized by excess of urates in the urine. In the bilious cases alkalies and laxatives, especially calomel, are indicated. Among the hepatic stimulants corrosive sublimate, podophyllin, and ammonium benzoate were mentioned.

Dr. W. S. Christopher, of Cincinnati, referred to Schiff's experiments, which show that the liver is concerned not only in transforming into harmless compounds the leucomaïnes formed in retrograde tissue metamorphosis, but also in changing a somewhat similar class of substances, viz., ptomaïnes. In the digestion of albuminous substances the action of the gastric juice is first to change the albuminoid into syntonin and para-peptone, two substances exactly alike, except that the first is capable of further change into peptone under the action of the gastric juice, while the second cannot be so changed by this secretion. But on reaching the duodenum the latter is changed into two forms of peptone,

ANTI-PEPTONE AND HEMI-PEPTONE,

which differ from each other like the syntonin and para-peptone, the anti-peptone undergoing no further change under the influence of the pancreatic juice, while the hemi-peptone is further split up, and among the products are found leucin and tyrosin. In all probability true pancreatic digestion of proteids stops here, and the further change into indol and skatol requires the action of the micro-organisms present. After the micro-organisms have taken hold, the number of decomposition products increases, and among them we find a small proportion of ptomaïnes, the alkaloids of putrefaction. For this condition the speaker has been accustomed to use the term

HYPER-DIGESTION.

If, now, coupled with this formation of ptomaïnes in the intestinal tract, we have actual hepatic incompetence, or relative incompetence, due to the inability of the liver to deal with the excess of ptomaïnes brought to it, some of the latter are carried into the general circulation and produce their peculiar effects through the medium of the central nervous system, like all other alkaloids. Since ptomaïnes can only be formed from nitrogeneous food, it follows that, in the treatment of these cases, such food should be withheld. The speaker was accustomed to use, in these cases, calomel as a preliminary cathartic, and soda phosphate afterward in the mornings, both for its laxative action and its property as an hepatic stimulant. He also employed salol, salicylic acid, and naphthalin as intestinal antiseptics. On the whole, his treatment was very satisfactory.

Dr. George W. Jones, of Danville, Ill., approved of the name "hepatic incompetence," given by the essayist to this class of cases. In treating these cases he used oil of winter-green as a preferable form in which to administer salicylic acid, and with excellent results. He also employed common salt in the food used by these patients.

Dr. George Wheeler Jones, of Danville, Ill., read an abstract of a paper, which he had prepared, on

CHOREA,

in which he held that chorea was due to certain atomic changes in the central nervous system produced in children having a syphilitic or tubercular ancestry, by means of certain poisons, particularly that of rheumatism. Habit chorea he regarded as nearly related to epilepsy, and probably not properly classified with ordinary chorea.

Dr. Larrabee, of Louisville, claimed that chorea, being always chronic, is therefore always caused by some preceding condition. It is common to see choreic movements commence in one extremity, then pass to others, and finally be followed in the same order by rheumatic effusion. Overwork is a frequent cause of chorea. Chorea produced by sudden fright may be followed by endocarditis, and rheumatic effusion into the joints. Sudden great emotions may produce very marked changes in the blood. The speaker had seen a leucæmia produced in the adult by an intense fright, and in this case chorea followed.

The last paper read before the Section was by Dr. J. A. Larrabee, of Louisville, and was entitled

SOME POINTS CONCERNING THE ETIOLOGY AND TREATMENT OF FEVERS IN CHILDHOOD.

In the handling of fevers in children, the essayist recommended an abundance of fresh air, antithermic rather than antipyretic measures, careful diet, frequent bathing, large draughts of water, and but little medicine.

Remittent and typhoid fevers are so much alike in children that they are usually not differentiated. In all probability typhoid alone occurs in children; such, at least, is the opinion of most authorities.

In the management of typhoid fever good hygienic surroundings must be maintained, if possible. In the early stages he was accustomed to administer ipecac and warm water to produce emesis, followed by one-tenth grain of calomel every hour, until purgation occurred. Then a bath was given. When malaria is suspected, he adds to this treatment quin. mur. dissolved in hydrochloric acid. Two days will be required to carry out this treatment, and at the end of this time the diagnosis of malaria will be settled, or the patient given a satisfactory start to his typhoid fight, this preliminary treatment seeming to lessen the subsequent severity of the disease. During the fever he used a great deal of water, both internally and externally, frequently making use of the cold coil to the head. He also employed minute doses of morphine (gr. $\frac{1}{200}$ in infants), many authorities agreeing that this remedy assists in the excretion of urea. Tully powder not infrequently relieves bad head symptoms.

Antipyretics of the acetanilid type should not be employed when carbonic acid is accumulating in the blood. He has had good results with phenate of ammonia, both in gastric and typhoid fevers.

With regard to alcohol, the speaker considered it a food only in the most limited sense. It is always followed by depression. It kills young tissues.

Overfeeding, he thought, was dangerous. He had never seen good results from forced feeding in typhoid fever, but had frequently found great curds in the stomach, at times when there was imminent danger from ulcers.

He was a believer in the wise, conservative provisions of nature. As far as possible, he liked to feed according to the appetite, and considered common salt a valuable addition to milk and water. The wasting in typhoid is rather that of muscle than of fat. In convalescence he advocated good diet, fresh air, hygienic surroundings, and occasionally citrate of iron and ammonia.

Dr. Jenkins, of Iowa, remarked that he practised in a malarial region, and believed that children are more susceptible to the malarial influence than adults. He believed

REMITTENT FEVER

to occur very frequently in children—more frequently, indeed, than intermittent fever. In the treatment of this disease he used calomel, paid attention to the skin, and administered quinine by inunction, by the rectum, or by the mouth. He agreed with the reader of the paper that overfeeding frequently complicates fevers, even in babes at the breast.

Dr. Johnson, of Indiana, stated that he had not found typical typhoid fever as frequent as the atypical. He approved of the differentiation of malaria and typhoid by means of quinine.

Dr. Moore, of Omaha, believed that great good results from keeping the bowels open in children, as he had found disease often due to "the plugging up of the cloaca magna." In any case of doubtful diagnosis, his advice was to give castor-oil.

Dr. Lawrence, of Ohio, had found the use of the cold pack frequently followed by good results.

Dr. Boyce, of Grand Rapids, had had good results in the use of antipyrine in typhoid fever. He also used quinia as a diagnostic agent.

Dr. W. S. Christopher, of Cincinnati, referred to a recent epidemic of typhoid fever in that city, in which the appearance of the disease in adults had been preceded by an unusually large number of cases in children. He had seen three cases in children aged nine, fourteen, and eighteen months, respectively.

Dr. Larrabee, in conclusion, wished to emphasize the importance of his quinine mixture, the muriate dissolved in hydrochloric acid.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 17, 1888.

ABRAHAM JACOBI, M.D., PRESIDENT, IN THE CHAIR.

Drs. E. F. Bruen, of Philadelphia, and **F. C. Shattuck**, of Boston, were invited to seats on the platform.

CARPENTER LECTURESHIP.

Dr. F. A. Castle, of the Board of Trustees, read the following clause from the will of the late Dr. Wesley M. Carpenter: "After the payment of my funeral charges and the expense of administering my estate, I give and bequeath five thousand dollars to the New York Academy of Medicine, with which to found a lectureship to be known as the Carpenter Lectureship, to be paid to the trustees of the New York Academy of Medicine, to expend the interest thereon annually for one medical lecture." Dr. Castle stated that the trustees had accepted the gift.

Dr. B. F. Westbrook, of Brooklyn, then read a paper,

PLEURISY AS A PREDISPOSING CAUSE OF PHTHISIS PULMONALIS.

He said that since it had been proven almost beyond doubt that the bacillus tuberculosis was the exciting cause of phthisis pulmonalis, it remained for us to inquire whether there were any demonstrable local conditions which might so affect the tissues as to render them specially liable to the invasion of this micro-organism. It must be admitted that something in the nature of a predisposing cause existed in susceptible individuals. There were instances in which the development of pleuritic disease, although non-tubercular in character, was shortly followed by pulmonary tuberculosis. The local inflammation might be taken as the indication of constitutional weakness which probably would have led to the development of the major disease sooner or later. In these cases the pleurisy should be regarded as a warning.

Cases of pleurisy antedating the outbreak of disease of the lungs might be divided into five classes:

1. Those in which pleurisy with effusion occurring in a person apparently in good health was immediately followed by evidence of pulmonary tuberculosis, which usually ran a rapid course to a fatal termination. This was a form of disease which was frequently observed both in private and hospital practice. Such a pleurisy was undoubtedly tubercular in origin, and formed but a part of the general disease. Its discussion was not germain to his subject.

2. The second class included those instances in which the sero-fibrinous pleurisy was followed by the slow development of chronic interstitial pneumonia, the fibroid phthisis of Sir Andrew Clark.

3. In the third class were cases in which an acute or subacute attack of sero-fibrinous pleurisy terminated in complete recovery, and was followed, after some months, by tuberculosis at one or both apices. It was usually observed in persons who were constitutionally weak or whose health had been injured by debilitating causes. Cases of this kind were not, he believed, very numerous, but yet were sufficiently common to have been seen by all physicians of a little experience.

4. This class included cases occurring usually in those of middle age or in the decline of life, in which a sero-fibrinous pleurisy had become chronic, and in which, on account of the density of the false membrane covering the lung, and the diminished pliability of the parietes of the chest, absorption had not occurred. They were typical cases of chronic serous pleurisy which had either failed to be recognized, or had been left to the mercy of that very unreliable agent, the *vis medicatrix naturæ*. It was nevertheless a fact that some of them finally developed tuberculosis, either in the lungs alone or in the disseminated form.

5. Cases of empyema, the appearance of which antedated the appearance of tuberculosis. This class was introduced only to make the list complete.

Dr. Westbrook gave the histories of cases illustrative of the second, third, and fourth classes, and said that in all the cases it would be observed there had been positive anatomical demonstration of pleurisy with effusion, with the exception of one sent him by Mr. Butler, whose diagnosis no one would doubt. The following conclusions were then drawn:

1. That sero-fibrinous pleurisy, apparently simple in origin and terminating in complete recovery, as far as the local manifestations were concerned, might be followed after the lapse of a few months by the development of pulmonary phthisis.

2. That, in all probability, the pleurisy in these cases acted as a predisposing cause of the tuberculosis.

3. That primary sero-fibrinous pleurisy might result in fibroid phthisis, with the subsequent occurrence of tuberculosis pulmonalis.

4. That fluid effusions remaining in the chest for a long time might finally so interfere with the nutrition of the lungs or of the body at large as to render it liable to tubercular inflammation, either local or general.

5. The rational deduction from these facts was that no case of pleurisy should be neglected; that after apparent recovery great care should be taken that the health of the patient was completely restored before he was lost sight of. When all signs of effusion had disappeared care should still be taken that the health of the patient was entirely restored before he was permitted to resume his former occupation. When there was a history of phthisis in the family, still greater pains should be taken; the patient should remain from business a longer time, and should have a change of climate, and entire mode of life if necessary, and should not be lost sight of by the physician for at least a year after his health had apparently been completely restored. When the patient had arrived at middle life, when the costal cartilages had lost some of their elasticity, an effusion should not be allowed to remain in the chest more than two or three weeks. If after aspiration the chest refilled, the operation should be repeated. When the fluid had been reabsorbed, but there was still dulness and feeble respiratory murmur at the base, the patient should be kept for a long time on the most efficient tonics and alteratives, with very liberal diet and plenty of out-of-door exercise. He should also be taught in the practice of respiratory gymnastics. In more delicate subjects he used passive motion to expand the chest, as by the inhalation of compressed air, or its equivalent, the use of the pneumatic cabinet.

Dr. Williams, of Brooklyn, then read a brief paper, discussing

SOME OF THE DETERMINING CAUSES OF PLEURAL EXUDATES.

After some general remarks he submitted three suggestions which he thought it would be profitable for those who wished to make an honest hand-to-hand fight in the treatment of pleurisy and its correlative diseases to remember.

First. Among determining causes of pleuritic exudates was hereditary or constitutional construction, with demonstrated richness of cell proliferation in inflammatory products, and proneness to organization. The subject of such a tendency would blanket his pleural surfaces with a pseudo-membrane in seeming disproportion to the exciting cause.

Second. Early pulmonary immobility, either regional or entire, consisting not in a circumscription of pulmonary movement by pleural disease, but a condition originating in fœtal life.

Third. Constitutional infection by the bacillus tuberculosis.

Dr. J. Blake White read some remarks on phthisis pulmonalis in persons in whom all signs of pleurisy had disappeared. He thought it had been well established that pleurisy not only frequently occurred in tubercular lung disease, but that it gave rise to tuberculosis in persons previously healthy. Expansion of the lungs should be cultivated after an attack of pleurisy, as thereby many cases might be prevented from degenerating into phthisis. The question of preventing as well as curing phthisis was largely one of increasing the lung capacity, especially at the apices, where there was naturally least activity. Systematic lung exercise in children, with judicious diet, would prevent phthisical tendencies and chest deformities as life advanced. In fibroid pleurisy, a disease which was both insidious and chronic, blisters, systematic exercise, and hygienic measures should be employed a long time after convalescence from the acute attack. His observations had tended to confirm the view that the bacillus tuberculosis was the result, and not the cause, of the phthisical process.

TREATMENT OF PREDISPOSITION TO PHTHISIS IN CHILDREN WHO HAVE HAD PLEURISY.

Dr. W. B. Wood read a brief paper on this subject. Between the natal condition of no disease and the time of well-developed disease, there lay somewhere that border-land, predisposition, a condition of the initial disease which was not phthisis, but which might be recognized and successfully treated; that, unrecognized and untreated, might ultimately become phthisis. The first physical manifestation of predisposition to phthisis was diminished breathing power, deficient respiratory function. The two great causes of deficient respiratory function in children were impeded nasal respiration, and thickened and immobile pleura at the base of the lung. Any treatment which would overcome these conditions constituting predisposition would, in the vast majority of cases, effectually prevent the development of phthisis in children. The treatment must be, first, securing free nasal respiration by proper treatment of the nose; second, a system of lung-gymnastics which would enable the child to take in and appropriate the air thus brought in contact with all the air-cells. Illustrative cases were given.

Dr. Brun, of Philadelphia, said it had been believed from the earliest history of medicine that phthisis was liable to follow pleurisy, and he thought it would be well to consider whether the reverse might not sometimes occur; whether the etiological conditions of phthisis might not, in turn, have a bearing upon the development of pleurisy. Within the past few years special attention had been devoted to this subject, and more and more cases were being recorded in which supposed primary pleurisy was demonstrated to have been of tubercular origin. The past winter he had seen two cases bearing on this subject. In one, the entire pleural surfaces were the seat of fibrinous pleurisy with adhesion. The patient died, and section demonstrated thoroughly the characteristic anatomical changes which were called tubercular, while no lesion was present in the lungs whatever. If a tubercular process in the peritoneum could' undergo resolution, as it often did, why might not recovery happen after the same process had taken place in the pleura or lung? Therefore he would lay more stress on the tubercular character of the pleurisy than Dr. Westbrook had done, and when recovery took place it might be attributed to a strong constitution, and the absence of the scrofulous or tubercular diathesis, as manifested in a tendency to cell-proliferation.

With regard to tapping, where absorption did not take place in sero-fibrinous pleurisy, he had usually found that in such cases the fluid was sacculated, and he had not derived the benefit from paracentesis which he had expected; therefore he put it off as long as possible. Pleurisy occurring in one with a tubercular or scrofulous tendency, or of feeble strength, should be watched carefully, as such patients were liable subsequently to develop pulmonary consumption. The after-treatment should not be one-sided. There should not only be pulmonary gymnastics, but the general body should be strengthened by exercise and other hygienic measures as well. He did not believe in attempting to restore the respiratory capacity by mechanical means alone. The respiratory muscles should be developed, and the whole system fortified.

Dr. F. C. Shattuck, of Boston, thought the subject under discussion was a large one and of growing importance. We saw cases of pleurisy in both hospital and private practice in which the disease, although apparently primary, was followed so closely by tuberculosis of the lungs that we could not but regard the pleurisy as also tubercular. In a second class of cases, there was apparently complete recovery from pleurisy with effusion, yet there developed some time later tubercular phthisis. In still a third class of apparently primary pleurisy, recovery took place and the patients remained well. Having stated these clinical facts, he asked whether primary pleurisy due to cold ever existed. If it did exist, how common was it, and how common was primary tubercular process starting in the pleura? Strümpel had stated, in his "Text-book of Medicine," that pleurisy due to cold was, in his opinion, extremely rare. Dr. Shattuck had added a note stating that such might be the German experience, but it was not the experience of American physicians, because so many of our patients recovered absolutely and permanently from pleurisy. There were other European authors who were disposed to think that all cases of pleurisy, except those directly traceable to injury, infection from scarlet fever, etc., were due to tuberculosis, and Dr. Shattuck said he was himself coming to regard the facts as looking in that direction. In the light of the present day, tuberculosis might exist quite independent of an affection of the lungs, and be an entirely local and comparatively innocent condition. Heretofore the conception of tuberculosis had been associated in our minds with the death-certificate. If recovery took place more frequently in tuberculosis localized in the pleura than when in the lungs, it was due, he thought, to the very favorable conditions for the development of the bacillus tuberculosis in the lungs. The difficulty of finding the bacillus in the pleuritic effusion was acknowledged, and a negative result in the examination could not weigh against the positive findings in many cases. Our inability to account for the way in which the tubercle bacilli reached the pleural cavity in the first place had no weight in the argument. It seemed to Dr. Shattuck that the best possible kind of pulmonary gymnastics was mountain-climbing.

Dr. E. G. Janeway had within a year seen evidence strongly impressing him with the view that if our knowledge were always perfect, we would very frequently recognize tuberculosis as preceding what then were apparently cases of primary pleurisy. Post-mortem findings usually pointed to tuberculosis in pleurisy, although the clinical signs were apparently those of simple pleurisy. There were cases of pleurisy occurring in persons of rheumatic history, in which recovery took place without evidence of tuberculosis. Regarding the treatment of the effusion, there was a method which had sometimes succeeded when repeated aspirations had failed. It consisted in limiting the amount of fluid taken to less than one-third or one-half of the urine passed, and at the same time giving salt and the iodide of potassium in sufficient quantity to make the blood perhaps somewhat thirsty for fluid. Dr. Janeway cited a case in which the examiner failed to find tubercle bacilli in fluid withdrawn from the pleural cavity, when at death they were found in the mediastinal glands; and also other cases illustrating the necessity for care in basing a diagnosis upon the findings regarding the bacillus.

Dr. Westbrook closed the discussion, and said his paper was intended to present the clinical rather than the pathological aspect of the subject. He had not undertaken to fully discuss the question of tuberculosis. While he admitted that nobody was justified in making the positive assertion that a pleurisy entirely recovered from was not tubercular, on the other hand, it was equally presumptuous to say that it was always tubercular. He knew of no reason to suppose that the pleura, of all organs of the body, could alone become inflamed only from infection.

The President thanked the members of the Academy for their large attendance, and reminded them that it was through the efforts of Dr. R. C. M. Page, the Chairman of the Section in Practice, that the meeting had been arranged, and he would now call on that gentleman for his views on that subject.

Dr. R. C. M. Page, in reply, said that the subject had been so thoroughly discussed by the learned gentlemen who had preceded him, and the hour was so late, that he had nothing to add on the subject at present. He thanked the members of the Academy in general, and those of the Section in Practice in particular, for their large attendance and the interest they manifested in this important subject.

AMENDMENT TO THE CONSTITUTION.

The constitution was amended, extending the area of membership to the entire State of New York, and permitting those residing outside the State to become non-resident members. The latter were to have all the privileges of the Academy except that of voting.

A portrait of Horace P. Farnham was accepted, with thanks to the donors.

Correspondence.

XERODERMA PIGMENTOSUM.

To the Editor of The Medical Record.

Sir: The very interesting and instructive paper by Dr. R. W. Taylor, on "Xeroderma Pigmentosum," in The Medical Record of March 10th, was read by myself with more than ordinary interest, and, considering the chaotic state of every department connected with that affection, I take it that, in giving my views on the whole subject, I shall be guilty, possibly, of no greater sin than a breach of modesty. However, that matter or act needs no qualification, as we are all earnest laborers in the interests of mankind, and naught but good can come from an interchange of views, though the humblest contribute. But to return to our subject. I was not a little disappointed to find little or no mention of the pathogenesis of the disease, and as to treatment, to find the most intelligent efforts fruitless. Hence, if my ideas of its genesis, pathology, and treatment are far from the truth and ill-founded, we are none the worse off. I have never met with a case of xeroderma pigmentosum that I am aware of. However, in this connection it might be of interest to relate the following: Two years ago I was treating a young lady for acne rosacea. There existed and persisted beneath the left eye a small red spot, after the acne was cured. This spot I took to be a nævus. There subsequently appeared another in the vicinity of the first. Neither became pigmented; the epidermis was not raised. I concluded to treat them both by igni-puncture, puncturing the periphery thoroughly. The spot which appeared first was no larger than a pea, while the second was just visible. The effect was satisfactory; there was no further development in them or their vicinity, and they disappeared with scarcely any trace. It is questionable if this were a case of incipient xeroderma pigmentosum, yet, had I allowed it to develop unmolested, it might have proved itself to be such. Funk, it is stated in the paper, believes the disease to be one of microbic origin. I am also *firmly of that opinion*, after a comparative study of the two possible etiological factors, viz., some disarrangement in the order of the epiblast or mesoblast, or both, and the microbic.

To my mind the weight of evidence is in favor of the microbic theory; *e.g.*, were it of embryonal origin we would, beyond all question, have met the disease more frequently. Instead of a few cases and reporters, up to date, they would have been legion. Further, it would seem all the cases so far reported had occurred in large cities.

Although the social plane of none of the sufferers is given, I presume it was poor. Ordinarily the disease begins with an erythematous patch, or a number of them, beneath one of the eyes. It is curious why it should select this particular part of the facial epidermis. Obviously if it were due to errors in the arrangement of either the mesoblast or epiblast, or both, we would not expect it to occur in any particular spot; though as the order of the embryonal layers in forming the orbit is complicated, and cysts and embryonal tumors are common to that region, these are governed by laws, developing at puberty, or in old age, or following traumatism, etc. Malignant affections of the skin, of embryonal origin, occurring among children, are remarkable for their rarity; while serious, not to say malignant, diseases of that tissue, which are of parasitic origin, are exceedingly common. I have assumed that the morbific agent in the causation of xeroderma pigmentosum is a parasite, and that the xeroderma is the result of the direct action of the parasite upon the embryonal cells of the deep layer of the rete mucosum, and that the pigmentation is the sequel, likewise the carcinomata. It seems to me that the parasite elects to attack the epidermis beneath the eyes for three reasons: 1, The skin in that locality is delicate or less corneous, I think, than other parts; 2, the epidermis about the eyes of children, as all know, is more frequently irritated and subject to abrasions; 3, the epiderma here, in children, is almost constantly bathed with tears. With these propositions I would connect the following:

It is noticeable that in all cases, and those of the author of the paper in particular, the disease was more malignant in the upper part of the face above the mouth, and it also spread with greater rapidity in that region, and as it extended, or rather the farther it got from that locality, the less malignant it appeared. As remarked before, the disease starts with a well-marked, smooth, superficial erythema. This, it seems to me, would point clearly to some interference with the physiological processes taking place in the rete mucosum and corium, in fact, a pathological process in loco, viz., a destruction of the protoplasm of the cells of the rete mucosum—in other words, a thinning of the epidermis and an elongation of the capillaries of the papillæ. In my opinion the degree of redness depends upon the above conditions in the rete and corium. I may state, also, that I believe that the essential pathological changes are the work of a specific pathogenic micro-organism, which flourishes in the nitrogenous protoplasm of the young cells of the rete mucosum. In regard to the relationship between the red and pigmented phases, in the progress of the disease, I cordially agree with Dr. Taylor. It is more than likely, "with regard to the production of pigment," there first takes place an elongation of the capillaries, "following the destruction of the rete above and between them," with dilatation—in fact, the production of telangiectasis. Pick says the endothelium is swollen and folded so that it obstructs the lumen. As a matter of fact, a capillary hemorrhage would follow the degeneration of their epithelial walls. Hence, I would account for the pigmentation upon the following hypothesis: The chemical and physical decomposition of the hæmoglobin by light, heat, and possibly the presence of an acid—"the product of organic decomposition, as in all probability varieties of non-pathogenic organisms are associated with those of the disease," with the production of hæmatin. Ziegler, in writing of cutaneous extravasation ("Pathological Anatomy," sect. iii., pp. 100, 101), says: "A third portion of the corpuscles shrink up or crumble down into brown granular masses." "This lies free in the tissues, and often becomes darker in color with age" (Ibid.). Gussenbauer has referred the production of melanin in pigmented tumors to a decomposition of the blood escaped from thrombosed vessels within the tumor. Ziegler, farther on, in reference to cutaneous extravasations, remarks as follows: "A fourth, and that the greater portion of the corpuscles, and the products of their disintegration, is taken up by leucocytes, which gather in large numbers round the seat of extravasation, and even penetrate into it. The cells become, in this way, corpuscle and pigment carriers. The transformation of the hematin into brown pigment is completed within these cells, the corpuscles breaking up into minute granules. The pigment may be set free again by the disintegration of the carrier cells. Probably the cells have also the power of eliminating it without themselves perishing."

Dr. Taylor quotes Neisser on this subject as follows: "The pigment is distributed in isolated spots similar to melanotic tumors, and is seated in the deep layers of the epidermis, and rarely in the corium. The pigment is precisely similar to that of melanotic new growths, and differs from that of ecchymosis?" Pick, in reference to this matter (Ibid.), says: "Pigment deposit keeps pace *with the invasion* of the *vessels*, and with the *small-cell infiltration* of the *corium*. The *cell infiltration* is *undoubtedly* the *carrier* of the *pigment*."

As regards the development of the keratosic patches, there is plain evidence of increased nutrition. On the other hand, in atrophy we have sufficient evidence of nutritive changes, and their cause, *i.e.*, a disappearance of the capillaries and their essential environments. It is well to note in this connection that the disappearance of the capillaries is coincident with that of the pigment. Hence, *à priori*, the capillaries have much to do indirectly with every phase of the disease.

With reference to the development of carcinoma from the innocent-looking papilloma, or the keratosic patch, I would say that Cohnheim's hypothesis elucidates that pathological process very satisfactorily. I think papillomata contain a matrix of embryonal cells. The keratosic patches undoubtedly contain, at their base, an aggregation of the same cells, "which amounts to a matrix." In xeroderma pigmentosum the papillomata are situated in a diseased area, and likewise the keratosic patches. These, if adequately supplied with vessels, as a matter of fact, do, and are at all times liable to, give rise to carcinoma; more especially is this liable to occur when the tissues in the vicinity of the above growths are suffering from disease or traumatism. They are benignant by virtue of the physiological resistance presented by the tissues in their immediate vicinity, though any interference with the normal functions of these parts may, "as was the case in some of those reported," cause an obliteration of the capillaries, and subsequent atrophy and disappearance of the papillomata.

Treatment.—The method to which I would pin my faith, were I called upon to treat a case of this disease, is igni-puncture, using the galvano-cautery with medium-sized needle; thoroughly puncturing the spots at their periphery, and from their centre to their periphery. Possibly, in the case of the large verrucuous plaques the pointed cautery of Paquelin would be more suitable and effective. It is my belief if the disease be treated on its first appearance by this method, it will end its career there and then.

I am not aware that it has ever been tried, though in the report of Dubois-Havenith's case, it is stated that he treated the raspberry-sized tumors by cautery and ablation; and they returned in most instances. "No mention is made of the method or extent to which it was carried."

I remain, very sincerely yours,
Buchanan Klaphel, M.D.

Memphis, Tenn.

THE MICROBE OF YELLOW FEVER.

To the Editor of The Medical Record.

Sir: In your issue of April 7th there is a short paragraph stating that the microbe of yellow fever described and cultivated by Dr. Domingos Freire, of Rio Janeiro, "has gone the way of many other specific germs," your grounds for this assertion being that Dr. Gibier "denies utterly the existence of the germ claimed to be specific." This conclusion has evidently been come to under the impression that the Parisian bacteriologist just mentioned has had full opportunities for verifying in Havana, within the brief space of six weeks, the results previously obtained in Brazil by Dr. Freire, in such a manner as to warrant his abrupt denial of what he had so warmly approved while experimenting in Paris upon Dr. Freire's Brazilian cultures. That such has not been the case I think you will admit after hearing the particulars of that investigation.

Dr. Gibier saw his first yellow fever case on November 16th, at the military hospital of this city. Between that date and December 28th, he examined altogether *five* patients and performed *four* autopsies. He collected fresh blood from *four* of the patients and urine from three, besides the pieces of viscera and secretions from the cadavers. In the urine of the first patient he thought at first that he had recognized Dr. Freire's micrococcus, but afterward changed his mind, having "satisfied himself" that what he had seen were mere insignificant organic granulations. In the blood and secretions, as also in the sections of viscera, he failed to discover any micro-organisms, nor did he succeed in developing any colonies in his numerous attempts with the same pathological material. One of the tubes of agar-agar jelly inoculated by him with heart-blood and presented to a military colleague, did, however, develop a yellow superficial colony, which Dr. Gibier attributed to an accidental atmospheric contamination, although the constituents of the colony turned out to be a tetragenous microbe quite distinct from the plain atmospheric micrococcus with which he had thought it could be identified.

This scanty material, collected at a time when yellow fever was sporadic in Havana, almost the only cases signalled being those present at the military hospital, constitutes the sole foundation for the abrupt retractation of Dr. Gibier from his former enthusiastic advocacy of Dr. Freire's views; never considering that the sporadic and epidemic forms of the disease might not be identical, any more than the equivalent forms of cholera have turned out to be, notwithstanding their clinical resemblance. Other observers had previously noticed that the same yellow fever products which, in their hands, had given colonies when collected from epidemic cases, failed to do so with the sporadic. In collecting blood from yellow fever patients, Dr. Gibier was noticed to disinfect the skin with bichloride solution, but took no pains to remove any excess of the germicide which might remain and sterilize the drop of blood as it would ooze out on the surface. Neither does it appear that he varied his culture media as to acidity, alkalinity, etc., nor that he kept his tubes at a uniform summer temperature. Yet, in spite of such obvious deficiencies, Dr. Gibier does not hesitate to condemn as erroneous the results of Dr. Freire's patient and laborious investigations, and likewise all others that might claim to have obtained successful cultures from similar yellow fever products.

Dr. Gibier had brought over some cultures proceeding from Dr. Freire's own tubes, inoculated at Rio Janeiro, and shortly after his arrival in Havana, full of faith in their prophylactic virtue, he inoculated himself, and thought he had gone through the phenomena of an experimental attack of yellow fever. In this, I fancied at the time, and he now acknowledges, that he was mistaken; but after examining my own cultures from yellow fever blood and urine, obtained by me last summer in Havana, and cultivated in sub-acid agar-agar jelly, he has repeatedly declared that both macroscopically and microscopically they were identical to Dr. Freire's. This coincidence, one would think, should have checked his precipitancy, and induced him at any rate to wait until the epidemic season before formulating his conclusions.

The only excuse, if so it can be called, for such haste in a practised bacteriologist, must lie in his unacquaintance with the disease and in his anxiety to proclaim a new bacillus of his own, isolated from the intestinal contents of yellow fever cadavers, and which he believes better entitled than its fellow-claimants to be considered as the true yellow fever germ.

My object in bringing forward these facts is to guard the American medical public against hasty deductions, and to show that Dr. Gibier's researches have not in any way altered the previous state of the question, except in so far that he has added another microbe to the list of the possible specific germs of the disease.

I am, sir, yours very truly,

CHARLES FINLAY, M.D.

HAVANA, April 17, 1888.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 13 *to* 26, 1888.

TOWN, F. L., Major and Surgeon. Post Surgeon at San Antonio, Tex., will take charge of the office of the Medical Director at these headquarters, and perform the duties of that officer during his absence on leave. S. O. 51, Department of Texas, May 11, 1888.

APPEL, D. M., Captain and Assistant Surgeon. Will be relieved from duty at Fort Davis upon the arrival of Captain J. V. Lauderdale, Assistant Surgeon, and proceed to Fort Hancock, and report to the Commanding Officer of that post for duty. S. O. 49, Department of Texas, May 5, 1888, and S. O. 50, Department of Texas, May 9, 1888.

EDIE, GUY L., First Lieutenant and Assistant Surgeon. Will proceed, not later than the 25th inst., to Fort Concho, and report to Commanding Officer 8th Cavalry for duty as medical officer, in compliance with par. 13, S. O. 99 c. s., Headquarters of the Army. S. O. 49, Department of Texas, May 5, 1888, and S. O. 50, Department of Texas, May 9, 1888.

WOOD, LEONARD, First Lieutenant and Assistant Surgeon. Leave of absence extended two months. S. O. 114, A. G. O., May 17, 1888.

WALKER, F. V., First Lieutenant and Assistant Surgeon. Will be relieved from duty at Fort Ringgold, and proceed with Company D, 16th Infantry, to San Antonio; he will then report for duty to Commanding Officer Post of San Antonio. S. O. 49, Department of Texas, May 5, 1888.

HARRIS, H. S. T., First Lieutenant and Assistant Surgeon. Par. 12, S. O. 49, Department of Texas, May 5th, relative to him accompanying 8th Cavalry to Department of Dakota, is amended by par. 1, S. O. 50, Department of Texas, May 9, 1888. Par. 1, S. O. 50, Department of Texas, May 9th, is revoked by par. 1, S. O. 51, Department of Texas, May 11, 1888.

HARRIS, H. S. T., First Lieutenant and Assistant Surgeon. Will be relieved from duty at Camp Pena, Col., and proceed to San Antonio, where he will report to Commanding Officer, Battalion 16th Infantry, for duty as medical officer with that battalion to its destination in Department of the Platte. Upon completion of this duty, he will return to his proper station, Camp Pena, Col. S. O. 51, Department of Texas, May 11, 1888.

CLENDENIN, PAUL, First Lieutenant and Assistant Surgeon. Par. 15, S. O. 49, Department of Texas, c. s. (relative to his accompanying 16th Infantry to its destination), is revoked by S. O. 51, Department of Texas, May 11, 1888.

CLENDENIN, PAUL, First Lieutenant and Assistant Surgeon. Will proceed from Fort McIntosh to Fort Davis and report to Commanding Officer 8th Cavalry, for duty as medical officer with that regiment on its march to Fort Concho, from which place Lieutenant Clendenin will return to his proper station. S. O. 51, Department of Texas, May 11, 1888.

Sutherland, Charles C., Colonel and Medical Director. To inspect the medical department at St. Francis Barracks, Fla., Fort Barrancas, Fla., Mount Vernon Barracks, Ala., and Jackson Barracks, La. S. O. 100. Division of the Atlantic. May 19, 1888.

Brown, Harvey E., Major and Surgeon. Directed to continue on duty at Fort Barrancas, Fla., until further orders. S. O. 115, A. G. O., May 18, 1888.

Kimball, J. P., Major and Surgeon. Leave of absence extended two months. S. O. 117, A. G. O., May 21, 1888.

McCreery, George, Captain and Assistant Surgeon. To accompany Seventh Cavalry from Fort Meade, D. T., to Fort Riley, Kan. From Fort Riley he will return to Fort Meade. S. O. 42, Department of Dakota, May 17, 1888.

Wyeth, M. C., Captain and Assistant Surgeon. Will be relieved from duty at Fort Barrancas, Fla., at the expiration of his present leave of absence, and will report in person to the commanding officer at Fort Huachuca, Ariz., for duty at that post. S. O. 115, A. G. O., May 18, 1888.

Kneedler, William L., First Lieutenant and Assistant Surgeon. Will accompany from Fort Snelling, Minn., that portion of the Twenty-fifth Infantry destined for Fort Shaw, M. T. From Cascade, M. T., he will accompany the portion of the Third Infantry en route from Fort Shaw, M. T., to Fort Snelling, Minn. S. O. 40, Department of Dakota, May 14, 1888.

Robertson, R. L., First Lieutenant and Assistant Surgeon. Will accompany from Fort Keogh, M. T., the Fifth Infantry to the Department of Texas, returning to his station on the completion of the duty. S. O. 43, Department of Dakota, May 18, 1888.

Ewing, C. B., First Lieutenant and Assistant Surgeon. Will accompany the Twenty-second Infantry, as medical officer, to the Department of Dakota, returning to his station on the completion of the duty. S. O. 56, Department of Missouri, May 17, 1888.

Banister, W. B., First Lieutenant and Assistant Surgeon. Granted leave of absence for two months, with permission to apply for an extension of twenty-seven days. S. O. 119, A. G. O., May 23, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending May 19, 1888.

Kershner, Edward, Surgeon. Detached from U. S. S. Pensacola and wait orders.

Sayre, J. S., Assistant Surgeon. Detached from U. S. S. Pensacola and wait orders.

Jones, W. H., Surgeon. Detached from Navy Yard, League Island, and to Pensacola.

Cooke, G. H., Surgeon. Ordered to the Navy Yard, League Island.

Crawford, Millard H., Passed Assistant Surgeon. Ordered to the Vandalia.

Wieber, F. W. F., Assistant Surgeon. Detached from the Vandalia and ordered home.

Stone, E. P., Assistant Surgeon. From Naval Hospital, New York, and to the Pensacola.

Harmon, G. E. H., Passed Assistant Surgeon. Commissioned a Surgeon, May 12th.

Dickson, S. H., Passed Assistant Surgeon. Detached from the Receiving Ship Dale, and to Marine Barracks, Washington, D. C.

Nash, F. S., Passed Assistant Surgeon. Ordered to the Receiving Ship Dale, in addition to present duties.

Ruth, Melancthon L., Surgeon. Granted one year's leave of absence from date.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending May 26, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	5	3
Scarlet fever	175	25
Cerebro-spinal meningitis	3	3
Measles	184	12
Diphtheria	154	56
Small-pox	6	5
Yellow fever	0	0
Cholera	0	0

In making Vaginal Examinations, soap is the best lubricant for the finger. It is cleaner and more slippery than oil or vaseline, and more easily removed from the hand, which is soon needed for something else; besides being more agreeable to the patient.—*Annals of Gynecology.*

Succi, the Fasting Man.—The Accademia Medico-Fisica of Florence has just given a diploma to Signor Succi, on the occasion of his having completed his thirty days' fast. The document runs as follows: "We, the undersigned, do certify that Signor Giovanni Succi, of Cesenatico, in the Romagna, African traveller and explorer, has completed at Florence a fast of thirty days—from the midnight of the 1st to the midnight of the 31st of March of this year—subjecting himself to all the regulations imposed by the Committee of Surveillance created *ad hoc*, and to all the scientific observations of the Commission nominated by this Academy, the results of which will be made *publici juris* at as early a date as possible. We further declare that by his courageous experiment, and by his scrupulous fulfilment of every moral pledge undertaken by him toward us, Signor Succi has deserved well of science." Then follow the signatures of Professor Angiolo Filippi, President of the Committee of Surveillance, and of Dr. Vincenzo Crapolo, his secretary; of Professor Luigi Luciani, President of the Academy, and the Secretary of its proceedings, Dr. Aurelio Bianchi.—*Lancet.*

Morning Sickness in the Husband.—At the meeting of the Obstetrical Society of Philadelphia, held April 5, 1888, Dr. Hamill reported the following case: "The occurrence of morning sickness in the husband, after the fact of pregnancy is known or suspected, I have frequently noted. The case I would report is unique, from the fact that the sickness appeared in the husband at such an early period of pregnancy. Two weeks after the appearance of menstruation for the last time, the husband had daily morning attacks, and not until it was time for the next menstruation had the woman any other evidence that conception had taken place, and then she failed to menstruate. The husband continued having the attacks for two months. During her previous pregnancies the husband had suffered from the same attacks, but not until they were both cognizant of the fact." Dr. William Goodell remarked that Sir Francis Bacon had written some lines on this subject, the substance of which was that "loving husbands so sympathize with their pregnant wives that they have morning sickness in their own person." A writer in *The Lancet* of May 4, 1878, p. 666, also refers to a case in point which occurred in his own practice. In this case the husband's nausea and vomiting began and ended with his wife's.

Considerable Antifebrine.—Dr. Albitski reports a case of phthisis treated by Kremyanski's method, in which over twenty thousand grains of antifebrine were consumed in one year.

Original Articles.

ON THE ELECTRICAL TREATMENT OF DISEASE OF THE UTERUS.[1]

BY SIR T. SPENCER WELLS, BART., F.R.C.S.,

LONDON, ENG.

I HAVE had perhaps a longer and more varied experience than most men in dealing with uterine diseases, especially those which are characterized by overgrowth. I have so constantly had to regret the inefficacy of medical treatment, and the results of surgical operations, though sometimes brilliant, have often come so short of my desires, that I have, for many years past, fallen into a frame of mind readily disposed to listen to any suggestion of a mode of treatment which offered a reasonable chance of success, and avoided the risks and perils attending bolder practice.

So when reports reached me from Paris of what Dr. Apostoli was teaching and doing, they came with a welcome ring. Electro-therapeutics were no novelty to me. More than thirty years ago, I had put galvanism to the test, and had gathered, in various ways, evidence of its potency both in destroying and repairing tissues. What I had learned of the treatment of ulcers by galvanism was published in 1849, by Golding-Bird, and may still be read in an appendix to his book; but his son and Mr. Nunn are the only surgeons, so far as I know, who have made much use of the practice. Not long afterward I tried the galvanic stem-pessaries of Simpson in amenorrhœa, and have used them until now, with occasional good result. I knew also what Radford had done with galvanism in the treatment of uterine hemorrhage, and what Simpson had taught us as to the influence of galvanism on uterine contraction in labor. I have repeatedly made use of the galvanic cautery in various ways, and have very often removed masses of epithelioma, or the cervix uteri itself, by a platinum wire heated by a battery, and used as an écraseur, with very satisfactory results. Quite recently, with Dr. Goddard, of Highbury, I removed a cervix uteri without the loss of one drop of blood. My attention was, later on, attracted to the electrical work of the French and Americans in reference to fibroid tumors of the uterus. This was so little satisfactory that it dropped out of notice. Our English experiments were not more encouraging, and surgical enterprise seemed destined to throw into the shade all less dazzling endeavors.

In the meantime, taking up the idea of the wonderful influence of galvanism upon the nutrition of tissues, Apostoli was unobtrusively resolving the problem of its right application in the treatment of abnormal growths and exudations. His published observations were so interesting, and the reports of eye-witnesses were so confirmatory, that in the autumn of 1886 I determined to see and judge for myself. I went to Paris, and was received frankly and cordially. Dr. Apostoli explained to me his views, and demonstrated his mode of procedure. He threw open the records of his daily practice, and gave me the opportunity of verifying his diagnosis, and witnessing his treatment of the cases actually under his care. Besides this, he mustered for my inspection about sixty of the patients who had passed through his hands. I heard many of their histories in their own words, and could contrast for myself their actual condition of good health and activity with the symptoms reported in the early notes of their attendance, and the deformity represented in the plaster-casts of their bodies, taken before the tumors had been influenced by the galvanic current. I spent many laborious hours in what I may say was a rigidly sceptical examination of the evidence before me, seeking for weak points in the system and the resolution of theoretical objections.

The conviction was irresistible that, though the method might not have reached its point of perfection, the work, so far as it went, was good. If the women were not radically dispossessed of their tumors, they were symptomatically cured. Nothing but prejudice could have turned the back upon the facts; and it would have been unjust not to put the matter to further proof. This I have unhesitatingly done. If I have hitherto been silent, it was because I did not wish to prejudge the case. But I have not been inactive, for I wished that, if the utility of the method could be made as manifest here as elsewhere, it should be advocated impartially, and presented to the profession upon reasonable grounds.

The uterine diseases which come under Dr. Apostoli's care range through all degrees of fibroid development. He has to deal, as we all do, with simple cases of subinvolution, generally hypertrophy of the organ, with metritic deposits all round; polypoid excrescences in the cavity, thickening, more or less irregular, of the walls, and subperitoneal outgrowths, expanding into abdominal tumors. Practically, all these cases group themselves into two classes: First, those which give no trouble and may be left alone; and, second, those which threaten health and life by loss of blood, or, by mechanically interfering with the organic functions, cause a multiform series of distressing symptoms.

In the treatment of these conditions, instead of scraping and cauterizing the cavity with a curette, or caustics, or fire, Apostoli does the same thing with a pole of the galvanic battery. We give ergot, or mercury, or iodine, or bromine in the hope of altering the nutrition of the diseased mass; he sends a disintegrating current through it. We castrate to cut short a woman's sexual existence; he seeks to quiet down neurotic sensibility, and induce regularity of ovarian function. Where we proceed to a root-and-branch extermination, he proposes a denutritive paralysis of the uterine substance. Time will show whether, and how far, he surpasses us in his results.

But the novelty at present is not so much in the fact of electricity being used, as in the mode of using it. Others have tried the same means, but not in the same way. Former methods were uncertain, dangerous, and insufficient. The point that Dr. Apostoli has arrived at is this: He has studied the effect that certain currents will produce, he measures the intensity of those currents, and he has found the means of safely directing them, of proper force, through the diseased tissues, to insure the partial, if not complete disorganization, of these tissues, with the desired coincident relief of suffering, and often with restoration of general health.

It is the continuous galvanic current which is generally brought into action. For this purpose the operator must be provided with an apparatus which will guarantee him an unfailing current of at least 250 milliampères, or electro-therapeutic units. I may say, in passing, that it may probably be found convenient to speak of milliampères as *units* of current strength—10, 20, or 60 milliampères, for example, would be 10, 20, or 60 units. In practice at the hospital or surgeon's residence, a battery of Leclanché cells answers admirably. It is enduring and easily manageable. For work at the patient's home a portable battery of the bisulphate of mercury is convenient, but it requires great care and frequent renewal. An indispensable accessory is the galvanometer. With a fractional deviation, it gives a measure of the intensity of the current passing. The graduation should rise to 250 units or milliampères, though this intensity is rarely wanted. Before every operation the perfect working order of battery, galvanometer, and conducting wires should be ascertained. As it is a characteristic point in the Apostoli practice that the galvanic current should be carried either into the cavity of the uterus or into the substance of the tumor, appropriate sounds and trocars are essential. To avoid loss of power by action on the metal, the sounds are made of platinum. For punctures with a negative current, steel trocars are equally good; but when it is intended to transmit a positive current, a certain length of the sharp end of the trocar must be of gold. All that portion of the sounds and trocars passing through the vagina, from the handle of the instruments to the mouth of the uterus or point of puncture, must be insulated. Before every examination or operation, the closest attention should be given to antiseptic precautions, both as regards the patient, the operator, and the instruments. During the whole course of the treatment, vaginal irrigations, with sublimate or phenol, are never to be neglected.

---

[1] Read at the Brompton and Sussex, England, Medico-Chirurgical Society.

The labors of Apostoli have expanded and given a definiteness to our knowledge of the special power of galvanic currents in the treatment of uterine diseases, and of the mode of applying the current in a way which I may thus resume:

In the first place, we have learnt from him better to understand the double action of the uninterrupted continuous galvanic current. The one action is purely local, and coincident with the flow. The tissues immediately in contact with the pole which delivers it are decomposed. The bases and acids of the substances and fluids acted upon are set free; and, according to their nature, produce cauterization of the surrounding parts, independent of any thermic influence. This effect is local, immediate and visible. The second action is due to the interpolar passage of the current. It is a *trophic* action influencing the nerves, vessels, and lymphatics, followed by molecular changes so as to modify the nutrition of the tissues through which the current goes, and varying according to the pole employed. The effect of the direct and of the secondary counter-current is durable; and, whatever may be our interpretation of it, it is remedially of far more importance than the mere galvano-chemical cauterization.

Secondly, though the coagulating power of the current passing from the positive pole was known from the writings of Ciniselli and A. Tripier, we have had disclosed much more since as to the distinctive character of the action of the currents from the two opposite poles. It was with the positive current that Apostoli began his attack upon uterine fibroids, because of the more striking nature of the hemorrhagic symptoms, and it was the speedy relief of this great trouble by the production of a hard, dry eschar and resisting cicatrix which encouraged him to persevere. The eschar resulting from the alkaline caustic action at the negative pole is just the contrary, softening and liquefying, and tending to promote discharge and hemorrhage. Logically enough, its dissolvent powers were applied to the opposite class of cases, where there was no hemorrhage, and the object was rather to reduce the bulk and solidity of compact masses of fibroid material. Experience has proved this to be as good in practice as in principle. The positive pole is therefore designated as anti-hemorrhagic or hæmostatic, while the words hemorrhagic or denutritive are applied to the negative pole.

Thirdly, Apostoli has taught us a much more satisfactory way of utilizing these currents in uterine diseases. His predecessors had used currents which were generally uncalculated and ineffective. They were not often strong enough to do much good, yet at other times sufficient to bring about mischievous results. They were brought into play in an ill-judged fashion, and when used by means of puncture the punctures were made through parts which ought to have been left untouched. Now, the operation is performed under such control as to be a matter of measurable certainty. A strong and regular current is at command. By means of the galvanometer a knowledge of the exact intensity of the current employed is insured. The dosage can be regulated in proportion to the cauterizing and trophic effects considered necessary. A current of high intensity can be made to traverse the tissues inoffensively, and brought out through the abdominal integuments in a dispersed fashion, without more than a temporary blush, and made to complete the circuit through the cutaneous electrode embedded in wet clay. Than this clay nothing as yet has been found more effectual. Then, by insisting upon the intra-uterine introduction of the current by means of the uterine sound, or its direct interstitial application through the inattackable trocar, a certainty of action is obtained which is otherwise out of reach. The whole performance is thus strictly at the will and under the control of the operator, who, granted his mastership, wants no other guide either as to the dosage, direction, or duration of the current, than the facial expression of the patient, or her declaration of tolerance.

Fourthly, other important points upon which we have clear and definite information are the modifications which this treatment requires according to the varying nature of the cases, and the successively changing circumstances of each case as the treatment is going on, and the wide range of uterine affections to which it is adaptable. Given a tumor and a current, there is no such thing as reciprocal automatic action. At every step of the process of cure, deliberation, judgment, and promptitude of resource are challenged. One day there is an unaccountable power of endurance, another an exaggerated sensibility; one day a perplexing structural resistance, another an easy flow of current, all which have to be taken cognizance of, and throw an ever-recurring strain upon the mindfulness of the surgeon, enough to baffle book-guided novices, and make inestimably valuable the more than five years' experience to which we can recur for counsel. A field, too, is opened up for exploration among the infinitely multiform presentations of disease of the female generative organs, untraversable by the limited powers of any one man, but to which Apostoli has pointed the way. This will be the work of the coming generation.

Lastly, there are several interesting questions upon which the work of Apostoli has thrown a new ray of light, such as the dangers and difficulties of the procedures; their being a cause, or the reverse, of subsequent sterility; the practicability of applying the treatment in cases where the uterus is impenetrable; the permanence of the benefits derived from the treatment in the mitigation of the symptoms and the reduction of the tumors; the relation of the menopause to the production or dispersion of fibroid enlargements. It would take up too much of your time if I were to consider these in detail, and it is needless, as Apostoli himself is here, on the invitation of your President, to give any required information.

But admit that there may be danger in treating our patients by electricity. Is this a reason for rejecting it? What surgical operation is free from risk? Would common-sense sanction our leaving disease alone till science has reached completion, and skill infallibility? The danger lies, not in the method, but with the operator; and the moral is, that no man should undertake this work till he has qualified himself to do it well.

Then as to the permanence of cure, where cure there has been, one can only say that though five years and a half is but a short term to form estimates upon, when we are assured that during that time the return of symptoms, or the necessity for further measures, has been quite exceptional, it augurs well for the future, and the objection of the possibility of relapse becomes of little weight.

Again, when Apostoli tells us that some of his patients now under treatment are women in whom the tumor developed after the menopause, no trace of such a growth having previously existed, what are we to say to the principle of Hégar's operation? To say the least, it would limit castration in the treatment of uterine disease to the cases where loss of blood is the prominent symptom in younger women. I might go on much further, but I think I have said enough to show that whatever may be, or may not be, the merits of Apostoli's method, we have made, since he began his work, a distinct scientific advance. And coupling the specific information we have thus acquired with our previous diagnostic tact and pathological exactitude, it appears to me that we are in a better position, even supposing that circumstances hinder the personal practice of the method, not only to discuss the abstract principles upon which it is based, but, as consultants, to pronounce upon its respective applicability to the cases submitted for our opinion.

There are conditions of fibroid tumors in which it would seem to me almost idle to suggest electricity. A polypoid growth from the mucous surface of the uterus, projecting into the cavity, or perhaps through the os, can be so easily and expeditiously taken away that I should not think of any slow or gradual process. Neither does it appear very probable that a subperitoneal outgrowth from the body or fundus of the uterus could be in any great degree affected by any current that could be made to reach it. Myomotomy would be then the work of minutes, and the risk scarcely worth mentioning. Even large solid tumors, the removal of which means the removal of a great part of the uterus, have been successfully removed by me and others, and success has increased with experience. But the risk must be always great, and there are tumors so large, or with such intimate connections, that no prudent surgeon would meddle with them. Here, surely, is the occasion for the electrician to show his power. His method is a new resource for a desperate condition, and should be welcomed as such. It has been successful in such cases; if not completely so, yet to a degree which has rendered life enjoyable. No weak prejudice should stand in the way of recommending a trial under experienced guidance.

Where the object is mainly to suppress hemorrhages, electrical treatment has decided advantages over other practices. Should the tumor be growing, but not advanced beyond the limits of reasonable surgical interference, balancing the comparative risk I should be disposed to put the matter to the test; since, in case of failure, the more hazardous operation of removal can still be done. In my opinion, with the option before her, it would be neither wise nor charitable to give a patient strong advice in favor of an immediate cutting operation.

Experience seems to show that there is a group of cases, numerous as they are troublesome, of chronic metritis with enlargement and surrounding deposits, which may be cited as pre-eminently eligible for electric treatment. They are, as regards the patient, painful and exhausting. To the judicious surgeon they are exasperating by their rebelliousness, and in some rash hands they have opened the way to practice more lamentable than the disease. It will be one of the crowning merits of electro-therapeutics, if proved to be equal to bring relief to these patients. Recent reports give good reason to hope that this end may be realized by a careful use of the positive galvano-puncture.

We have not, I am inclined to think, taken heed enough of the work of Tripier and Apostoli in reference to various disordered states of the uterine appendages. The soothing effect of the vaginal or uterine bi-polar application of the induced current, in some distressing forms of ovarian neuralgia and of vaginismus, is said to be marvellous and enduring.

As a last word, I may say that we are face to face with an important revival; and though some American surgeons have gone before us in its acceptance, nowhere more than in our own country has there been shown an open-minded readiness to weigh fairly all the evidence which Dr. Apostoli has to set forth in support.

In London we have heard, through the medical journals, of some failures, of one death, and of more than one accident, probably due to the inexperience of the practitioners. But we have far more encouraging reports from Edinburgh, and if some member of this society who combines sufficient knowledge of electrical science with practical experience of the diagnosis of uterine diseases, and of the treatment by other methods, will carefully put to practical test the conclusions already arrived at by Dr. Apostoli, I am very hopeful that the result will not be disappointing.

SOME CLINICAL OBSERVATIONS ON DIPHTHERIA AND VERATRUM VIRIDE AS THE BASIS OF TREATMENT.[1]

By J. M. BOYD, M.D.,

KNOXVILLE, TENN.

I propose to present some points founded on bedside study of diphtheria, and to suggest that plan of treatment which has proven most efficient under my own observation.

So far as I have any knowledge, this ancient and much dreaded scourge made its first appearance as an epidemic in East Tennessee in 1858, only thirty years ago. Then its outbreak was in Jefferson County, a case having been brought there from North Carolina. Thence its spread was rapid and its prevalence marked by great fatality.

In 1860 I saw one case of the disease in Knoxville.

In 1861 and 1862, having changed my residence to Jefferson County, the opportunity to see diphtheria was frequent, and in its virulent form and on the very spot where it had first found footing in East Tennessee, and where its fatality had been so notable since 1858. There my observation was extensive, and I realized fully that the results of treatment were, as a rule, unsatisfactory, for it too often happened that every child in a stricken family perished. For the first seven years after the war Knoxville had almost an immunity from diphtheria. About 1874 occasional cases were reported, and our mortality table has shown them each year since. But Knoxville has had, up to the present time, no such epidemics as have visited so many localities in our section of the State since its advent in 1858. So much for its local history and for the opportunity to make a practical study of diphtheria.

It is not the purpose of this paper to discuss the etiology of the disease under consideration, nor yet to consume our time in pushing any of the special views of its pathology.

These branches of the subject had better be delegated to those who are fitted to make elaborate research in the field of causation and in the essential nature of disease.

It is especially to the treatment that I wish to engage the attention of this body, and particularly to the modifying and benign influence of veratrum.

And while the idea about to be advanced may be earnestly combated by those who hold to the opinion of the accredited depressant influence of the drug, and to the view of the asthenic nature of diphtheria, I beg to submit, in maintenance of the plan of treatment now proposed, the following facts and argument:

On December 28, 1881, I was called to see a child in this city, aged sixteen months. I found a well-defined and vicious case of diphtheria in the person of my little patient, which in a few days terminated fatally.

During the course of this case a babe of Mr. L——, aged four months, and under the same roof, was attacked. It, too, was a case of marked severity, as shown by the rapid, hard, small pulse, the sallow skin, the range of fever, and the twitching of the muscles of the extremities.

---

[1] Read before the Medical Society of the State of Tennessee, at its Annual Meeting, April 10, 1888.

At the end of five days the larynx was invaded and croupous diphtheria became a serious complication, and about the same time the nasal passages displayed false membrane and the nostrils were entirely occluded. Impossibility for the child to suckle added inanition to the danger of the situation.

The membrane covered the fauces, and protruded from the anterior nasal aperture in white hemispheres. The pulse was 180, small and thready, and sepsis was beginning to oppress the little sufferer. The grandfather of the child, Dr. W. Whitson, a practitioner of prominence of Jordan Valley, Tenn., was in daily correspondence with the mother, and suggested through her that a drop of Norwood's veratrum would be warranted if the pulse could not be controlled by less. I was then giving veratrum in smaller but increasing doses, and at once gave a drop, repeating it every two hours till the pulse fell to 80 per minute. This seemed to me at that time to be a very large dose for a four-months-old child; but after it had been given four or five times, and the pulse had dropped to this below-normal rate, a less quantity easily held it there.

Snow under sunshine never melted away more surely than did this membrane under the favoring conditions incident to the influence of veratrum. Within the following twenty-four hours the child was able to nurse, and its recovery was rapid.

The lesson was not lost, for, as other measures were unchanged, the only possible influence to which such a brilliant result could be attributed was to the effect of veratrum.

Can it be that there is an antiseptic or an antidiphtheritic agency exerted under the full influence of this drug? Could rest, so important, we know, to the recuperation of nerve-force, explain the rapid recovery in this case?

The patient was rested when it was first attacked, and the disease progressed until asthenia and sepsis threatened at any time to terminate life. Facts would make the opinion respectable that there is an antidotal virtue in the positive impression of veratrum.

But setting aside all claims to value as an antidote, the controlling power of the medicine can, on other grounds of merit, be presented, I hope, with sufficient reason to invite favorable consideration. Since the occurrence of the case above cited, observation has verified the good results of this therapeutic agent in diphtheria. In the six years since, sixty-seven cases have fallen primarily to my care, and a number of others in which I have had a consultant relation, and, under the timely use of veratrum, its claims to the merits of extraordinary efficiency have never disappointed me. And often in a single case conditions have occurred which offered more than once a demonstration of its value.

And the cases upon which the conclusions have been reached which have prompted this paper have not been questionable ones. Many of them have not been mild, but every one asserted as a basis for this record has been a decided case.

There has never been a malignant epidemic of diphtheria in this community, but we have often had individual cases of malignant type, and a fair share of such have fallen to the veratrum treatment. And I am prepared to make the assertion that the *early and decided use of veratrum*, as the basis of treatment, offers better promise of good results in diphtheria than does any other plan the effects of which I have had opportunity to witness.

It should not be used merely as an incidental measure, but it should be made the *basis of treatment*. To slow the pulse should be the *sine qua non*. To say it roundly, all the world has used veratrum in diphtheria. But it is a very different use of it when, *as an essential feature, it is made the prime purpose to slow the heart's action as the basis of treatment*.

Pardon the seeming immodesty, but the comparison answers my purpose for illustration: Everybody used carbolic acid, but it remained for Mr. Lister to present its use to the profession as a basis of antiseptic surgery.

Upon being called to a patient we find the dull, sallow complexion; the pulse is 112 to 140, hard and wiry, and subsultus is observed; cervical glandular enlargement is revealed to the touch, perhaps to the eye. "Is your throat sore?" "Yes." "Have you had scarlatina?" "Yes."

Now the diagnosis is almost definite, and it only remains to examine the fauces to verify what is already most probable.

So characteristic is the pulse of diphtheria in its rate and tense, wiry nature [only resembling scarlet fever and some cases of cerebro-spinal meningitis] that the disease may with great certainty be predetermined if inflamed cervical glands add to the grounds of suspicion. In sixty-seven cases, in six years past, I have found only two instances of slow pulse, that is, only moderately accelerated, and they were mild in type.

As a rule, the viciousness of the attack may be better measured by the pulse-rate and tenseness than by any other symptom. There may be little membrane in sight, for it may be more post-nasal than faucial. But the pulse will tell the earnestness of the invasion.

And it is not influenced in its rapidity or fulness by physical exertion, as in anæmia or asthenia, but keeps its even tenor of speed and tension almost to the fatal hour.

Especially will the characteristic pulse be displayed in those cases where the membrane is deep set in an ulceration and presents a pearly white color, and is so thick that it can be tilted about by the touch of a probe by reason of its firm consistency, a condition of deposit common in malignant types. I dwell upon the character of the pulse because there is reason to believe that it is through measures addressed to the function of the heart that we are to find the most effectual means of controlling the disease. If the heart is slowed, the rate of circulation is slowed, and the inflammatory processes about the seat of the lesion are mitigated.

It indeed appears that, while under the positive influence of veratrum, the system has a tolerance for the poison, and there is demonstrated a resistance to further progress of sepsis and to the spread of the membrane. My observation, which has compassed one malignant epidemic and quite a number of cases scattered through the past fifteen years, has led me not to fear asthenia in the use of veratrum, but rather to fear exhaustion from continued rapid heart action. We know how often patients are lost from syncope. The *rationale* of such deaths is, that the entire organism, under the stress of a systole and diastole of 160 to 180 times per minute, falters and succumbs from great waste of nerve-force. Rather rest the tired organ, and the economy will take on recuperation and resistance to the invading poison.

Constant tension cannot long be borne, as witness the effect of continued strain upon the ciliary muscle—how, when overtaxed, sympathetic disturbance begets dizziness, headache, nausea, and palpitation; or of a not uncommon punishment in the army, where a soldier is forced to hold up overhead some weighty body, as a brick, how soon his burden becomes unbearable.

The best protection against asthenia in diphtheria is rest through means of a slow heart.

Is veratrum a sedative in the sense of a systemic depressant? I was taught as a student that digitalis was directly a sedative; now it is daily given as a heart tonic.

Remember that it was in a case of heart exhaustion in pneumonia that Norwood made the first medicinal use of his tincture, and under unpromising conditions, and the woman's pulse was brought down from 180 to 80 per minute, and under its full influence she recovered.

And in the free use of it, remember, Dr. Norwood, a year before his death, and only four years ago, stated before the Georgia State Medical Society that no instance of death from its sedative influence had been reported or had been brought to his knowledge, though it had been taken through mistake and design in teaspoon and tablespoon quantities many times. Of course, positive nausea sakelessly continued would contribute to a fatal result by exhaustion.

In accordance with such views as have now been expressed, the treatment of a case of diphtheria should be conducted as follows:

First mop all the membrane in sight with this standard mixture: Liquor ferri sub. sulph., 1 drachm; glycerine and water, 4 drachms of each. Don't use a camel's-hair brush. Moths eat off some of the hairs, and the stubs puncture the softened mucous membrane and carry the poison to the cellular tissue beneath, which deepens and extends the local lesion, but use a cloth mop on a slightly elastic stick. A fresh mop should be made for each application. Then give to an adult a tablespoonful of saturated solution of potass. chlorate, with three drops of Norwood's tincture, every two hours, the veratrum to be increased one drop, if necessary, each time until the pulse is brought down to 60 or 70 per minute.

It is usual to find that when once lowered a less quantity will hold it down. After each dose give eight grains of sublimed sulphur, to be swallowed dry, or, better still, to be blown into the throat with a tube. Rub the outside of the throat with kerosene-oil or some other irritant, and give thoughtful encouragement to a simple, nutritious animal food.

The application of the mop may be made at only alternate times that the veratrum is given, if the membrane is easily detached.

This constitutes the general plan of practice which has best met my views. It is not the purpose of this paper to detail all the measures which might be suited to the many phenomena of diphtheria. But it is proper that a statement should be made in evidence of the good effects of calomel in grain-doses every hour in croupous diphtheria.

It may be of interest to mention the quantity of Norwood's tincture required to control the pulse in this disease. It is tolerated well, as a rule, but in case nausea is disturbing to our purposes it must be increased cautiously and omitted occasionally. The purpose should be to increase from a moderate dose for the age of the patient, to whatever is necessary to bring the pulse to 70 or below in an adult within six or eight hours.

In a child aged four months, three and a half drops were reached before any impression was made, and then the pulse dropped to twenty-four beats per minute. A few drops of whiskey threw off the influence sufficiently for comfort in half an hour.

A child, two years of age, required five drops, and another, seven years, seven drops every two hours to bring the heart under control. These were the largest doses I have found necessary, and in all of them the morbid condition was steadily lessened under the conditions of slowed heart. All the above instances required less to control and keep a steady action than was necessary to first bring about sufficient effect.

I have observed that a decided and abrupt slowing of the pulse accompanied by more or less distressing nausea is always followed by a mitigation of subsequent symptoms. And so, too, in scarlatina but not in so marked a degree.

Dr. Galeazowski, perhaps, has the largest clinique in Paris. He has now treated over one hundred and thirty thousand patients, and sees about twelve thousand new patients a year. Here is a good place for the study of internal diseases of the eye. Dr. Galeazowski operates for cataract without iridectomy, but does not wash out the anterior chamber, which he considers dangerous. For granulations he frequently cuts away the entire conjunctival sac and then cauterizes. On making iridectomy he withdraws the knife very quickly, and the aqueous spurts out, the iris following, and is seized without introducing forceps into the chamber.—Dr. Tiffany, *Kansas City Medical Index.*

ON THE OCCURRENCE OF CONSTITUTIONAL SYPHILIS WITHOUT OTHER THAN INITIAL SYMPTOMS.

By W. S. GOTTHEIL, M.D.,

INSTRUCTOR IN DERMATOLOGY, N. Y. POLYCLINIC.

It is undeniable that the syphilis of to-day is not the malady described by the earlier syphilographers. To the laity, and perhaps also to the large majority of physicians, it is still the dread and terrible blood-taint, the contraction of which alters and colors, and perhaps ruins the entire future life of the individual that contracts it. But to many of those who see most of it, it is a mild and tractable disease, self-limited, save in its sequelæ, and, in the immense majority of cases, of most excellent prognosis. In no way, apart from the accident of most frequent communication during sexual congress, is it a venereal disease. Its history and its very probable, though still unproven, etiology place it among the exanthemata; and the benignity of its course is due to the same diffusion and general exhaustion of the soil that render measles a mild and generally harmless affection.

It is certain that it sometimes occurs and runs its whole course without the patient being aware of the presence of any serious ailment. And it is also certain that these mild and unrecognized cases may be centres of infection as potent, and more dangerous, than are severer and more manifest forms.

The subjoined set of cases is somewhat remarkable, both from the completeness of the confrontation and the plainness of the lessons that it teaches. It is rare that cases of syphilis acquired by sexual contact can be traced with any degree of certainty. The history as given by the patient is so utterly unreliable as to have been practically abandoned as a basis of diagnosis. The history here given is objective entirely; the cases were carefully studied from the beginning, and are all under observation yet.

Case I.—Mr. H——, aged twenty-five, showed me, in September, 1885, a suspicious urethral discharge. He had always been a free liver; had had gonorrhœa repeatedly during and since his early college days; had been dilated, divulsed, and finally cut by a distinguished specialist; and had at last settled down contentedly in a chronically gleety condition. There was sometimes no more than an infinitesimal mucous discharge, for months at a time; and then, without there being any appreciable cause, a profuse, gonorrhœa-like discharge would occur, yielding very promptly, however, to a mild lead, or permanganate of zinc injection. (This is the gonorrhœa of commercial travellers—the "cured-in-three-days-by-a-simple-injection" cases that are so often hurled at us.) His discharge had never been contagious, and had in no way interfered with his habits of life.

Being an intelligent man, he had learned to recognize these attacks as simple exacerbations of his gleet, and by careful observation he had acquired great certainty in his alleviating treatment. When, therefore, three weeks or so before he consulted me, there set in a discharge which obstinately resisted the usual measures, he examined himself carefully, and noticed on the lower urethral floor, just inside the meatus, a snow-white patch which he could not remove, and a small, hard lump underneath and connected with it. Then he thought it time to get assistance.

I found a typical chancre in the urethra, with an induration the size of half a large pea. Its mucous surface was covered with a pultaceous membrane; there was no loss, but rather redundancy of tissue. There was slight but perfectly characteristic enlargement of the inguinal glands on both sides.

For six weeks we waited for a corroborative symptom, and finally there occurred a slight defluvium capillorum. The chancre rapidly disappeared under the use of pledgets of cotton soaked in five per cent. solution of oleate of mercury in oleic acid, which were introduced into the urethra after each urination. He was put upon the protoiodide, but only took some fifty $\frac{1}{5}$-gr. Garner and Lamoureux pills.

From that day to this he has not had a single symptom of the disease. He has had no treatment other than that mentioned above, and has been practically under continuous observation. It would almost be a question whether the man has had syphilis or not, in spite of the typical induration and the slight but unmistakable secondary symptoms.

But I ascertained that, while carrying the chancre, and ignorant of its existence, he had had intercourse with three different women; and it chanced that all three of them came under my observation.

CASE II.—The first was his mistress, L. A——, aged twenty, a vigorous, healthy girl of Irish descent. He had had intercourse with her repeatedly during the four weeks of the discharge; and I was therefore not surprised to find that, when he brought her to me a fortnight after his first appearance in my office, there was an unmistakable hard chancre on the left labium minus. There followed in the next few weeks general glandular swelling and a distinct macular syphiloderm. Three months later there was a marked falling off of the hair. This loss of hair has been permanent in part; and her thinned eyebrows and scanty and short hair mark the malady that she has passed through.

But this is the only sign. She would not submit to regular treatment, affecting not to believe that she had syphilis. She has certainly not taken mercury for a month altogether. Yet she only showed any effects from the malady for the first three months after the initial lesion. After that she was entirely well; and now, thirty months after her chancre, and without any treatment at all, she is apparently, and in truth, as healthy a woman as any in the city.

CASE III.—The second woman, Miss K——, I did not see at all during the initial period; but I did see her and treat her in January, 1886, and thereafter. She then suffered from excruciating osteocopic pains, and had a double iritis—first the right and then the left eye being affected. Though she noticed no initial lesion, she describes minutely a maculo-papular eruption and a sore throat, the date of the appearance of which would about correspond with an infection in September of the previous year.

This woman was a spinster, aged thirty-six. It is difficult to believe that the infection at this particular time came from any other source than from Mr. H——. She was rather stout, of a weak, flabby, lymphatic temperament, and in her case the disease has worked its worst. Dependent upon her own exertions as a seamstress for her livelihood, she has endured hardship and privation, and has passed through a syphilis that has completely broken her constitution. Half her time, for the last two years, she has spent in the various hospitals; in some the disease has been recognized, and in others it has not. She has not had proper and continuous treatment; and now, at thirty-eight, she looks ten years older. Her hair is gray and her face is wrinkled, and treatment seems to have but little effect upon the chronic bone-troubles from which she suffers.

CASE IV.—At the same time Mr. H—— informed me that he had twice had intercourse with a married woman of his acquaintance during the time that he was carrying his chancre. I urged him to bring her to me, which he finally did. She is a young and vigorous woman, and has never had a single sign of the malady.

Here there was a case where, in a man of exceptional intelligence, there was an initial lesion so situated as to remain undiscovered for weeks, and so slightly felt that it interfered neither with injections nor with intercourse. The lesson is a plain one. In an ordinary man—in a person of less intelligence—it would have remained absolutely unnoticed from beginning to end. With the greatest truthfulness on the patient's part, no account of it would have been elicited if, in future years, the orthodox surgeon should attempt to get a history of specific disease.

Such a man would scatter the virus from his initial lesion in utter ignorance and without criminal negligence. And the thought naturally arises, how much more readily could this occur in the more extensive and less sensitive genital passages of the female. Women could contract the pox from a man apparently so healthy, save during the first few weeks, that no subsequent medical examination could find any trace of the disease; and could then, themselves, without knowing it, become centres of infection. It is easy to understand how a few vaginal or buccal mucous patches may pass unnoticed; but the foregoing history shows that the initial lesion itself, indurated and well marked as it almost always is, may be so situated as to entirely elude ordinary observation. It is impossible to tell just how often this occurs; but I am convinced that the immense majority of cases of syphilis are gotten from primary and secondary lesions, the existence of which is absolutely unknown to their possessors.

We see here three undoubted cases of syphilis, and one case of undoubted and prolonged exposure to its contagion. In all, the virus factor was one and the same; it came from one source. But the cell factor varied. The virus factor is a living organism; for on no other supposition can we understand the phenomena of syphilis and the other eruptive fevers. The amount deposited in the tissues of the recipient does not matter. Given a suitable soil, its increase is so rapid that the amount originally received is at once lost sight of. But the cells of the young and vigorous male promptly resisted the micro-organic invasion. They hardly needed any assistance; they would have done almost as well without any drugs at all. In the first female the conditions were so similar that the result was almost the same. What colonies did gain a foothold in various parts of the system were rapidly disposed of by the cells; and in her case, also, the malady, entirely untreated, would have run a mild and harmless course.

In the third case the soil was suitable and the cells were feeble. They offered but a poor resistance to the invasion, and succumbed in many places to the growing virus. She suffered considerable destruction of tissue from the disease, and suffers yet from its sequelæ.

The fourth case illustrates the chance exemption from contagion under circumstances most favorable for its occurrence. Her husband, with whom she had continuous sexual relations, has not, so far as I can learn, suffered from any specific trouble; and there is no doubt that she escaped infection entirely.

CASE V.—Finally, in August, 1887, I had occasion to discover accidentally, in another patient, a urethral chancre precisely similar to Mr. H——'s. Here, also, although ten months have now elapsed, there has been but one single secondary symptom—a slight alopecia.

78 WEST FORTY-SIXTH STREET.

DENVER PHYSICIANS AND TRANSITORY FRENZY.—A case in which this form of madness was alleged to occur is related editorially in the *Denver Medical Times*: "A young man falls in love with a variety actress, drinks and carouses with her, until he learns that she is a married woman. That his fair dulcinea should have deceived and have worked him simply for his money maddens and stirs up within his innermost nature a spirit of revenge, and he determines 'to get even with her.' He deliberately plans her destruction, bides his time, seeks her company, and with murder in his heart plays the agreeable, to throw her off her guard, and kills her. He is arrested, tried by jury, defended by a shrewd and clever criminal lawyer, acquitted. The verdict was 'transitory frenzy.' The most disgraceful part of the whole affair is that regular physicians should have aided by their *expert testimony* in the procuring of this most unnatural verdict. There was no insanity, temporary or otherwise, in this case, but there was method in the young man's madness."

SIMPLE AND RAPID STAINING OF THE TUBERCLE BACILLI, FOR THE GENERAL PRACTITIONER.

By H. P. LOOMIS, M.D.,

NEW YORK.

ALTHOUGH the causal relation of the tubercle bacilli to pulmonary phthisis may be questioned by some, no one, we think, can deny the diagnostic importance of their presence in the sputum.

The ability to recognize them enables the physician to diagnose the character of pulmonary disturbances earlier than he can possibly do it either by physical signs or any other symptoms. If the technique of the staining of the tubercle bacilli can be reduced to a simple form, so simple that no special technical training is necessary, then I believe that this most important aid to diagnosis would be as constantly employed by the practitioner as the chemical and microscopical examination of the urine in suspected cases of Bright's disease.

The method at present generally adopted in the laboratories—the Koch-Ehrlich method—is a complicated process requiring much practice and judgment, especially in the decolorization by nitric acid; it is not consequently adapted to the general practitioner's use, and will yield reliable results only in the hands of experts.

The belief that any technique which is simple and rapid, and reduces the staining of the tubercle bacilli to a mechanical basis, would be of use to the general practitioner is my reason for presenting the following method, which I have used for some time with uniformly satisfactory results.

While working with Professor Koch last spring, I found that in his personal examinations he made use of a solution of fuchsine known as Ziehl's solution, and hardly ever had recourse to a double staining.

To an expert, this gives without doubt the quickest staining possible, but because of the weakness of the solution, if made according to Ziehl's formula with the ordinary fuchsine purchased in this country, and of the lack of a contrast color, it does not yield satisfactory results to others. Making use of the principle which Ziehl has incorporated in his solution, viz., that carbolic acid can be substituted for aniline oil, I first stain the bacilli with a very strong solution of carbolic fuchsine, and then make the contrast staining by what is known as Fraenkel's solution, which combines the decolorizing and dyeing in one process.

This furnishes a specific staining for the tubercle bacilli—a deep-red color; the other elements in the sputum, the putrefactive bacteria, the pus-cells, the epithelium, taking the second color—blue.

The advantages of the method which I propose are these:

1. Simplicity; one solution is poured on the sputum and then the other, with no judgment necessary as to the amount of staining or to the decolorization; this makes the process simply a mechanical one.

2. Quickness and precision; the whole process occupying but two minutes.

3. The great intensity of color with which the tubercle bacilli are stained.

4. The solutions keep indefinitely, especially the carbolic solution, which cannot decompose like the aniline water solution of fuchsine; they are therefore always ready for use.

THE METHOD OF PREPARING THE SOLUTIONS.—First: The Fuchsine Solution. 1. Pour into a small bottle of alcohol, say a four-ounce bottle, enough fuchsine to form a well-marked layer over the bottom of the bottle, or, in other words, more than enough for a saturated solution. 2. Let it stand for twenty-four hours, shaking the bottle from time to time. 3. Into a four-ounce bottle, containing a five per cent. aqueous solution of carbolic acid, pour enough of the first solution to produce a distinct precipitation of the fuchsine, say, about ten or fifteen cubic centimetres—the exact amount is not important. 4. Shake a few times and set aside for twenty-four hours. This is the carbolic solution of fuchsine to be used.

Second: The Methylene-blue Solution. Put into a four-ounce bottle,

Alcohol	30	parts.
Distilled water	50	"
Nitric acid	20	"

and add methylene-blue until the solution is more than saturated.

THE METHOD OF STAINING THE SPUTUM.—1. Prepare two cover-glasses in the ordinary way, by placing a small portion of the suspected sputum on one cover-glass and, by means of the other, pressing it out between them into a thin layer; on sliding the cover-glasses apart, a thin film of sputum will be left on each cover-glass. Allow the cover-glasses to dry, and then, holding them firmly with a pair of forceps, prepared side uppermost, pass them rapidly three times through the flame of a spirit-lamp. 2. Hold cover-glass as before, and pour on it a few drops of the fuchsine solution. Then warm the cover-glass over a spirit-lamp until steam rises, being careful not to allow the fluid to boil; now let the solution on the cover-glass cool. 3. Pour off the fuchsine solution. 4. Pour on the cover-glass the methylene-blue solution, and after half a minute or so, the exact time is not important—5. Wash off the stain carefully with running water (a wash-bottle is convenient). 6. Dry the surface of the cover-glass which does not contain the sputum. 7. Mount on a slide in water and examine.

A little practice will enable one to carry out this simple technique with great rapidity; the only difficulty is in preparing the solution at first, but, as they will keep for months and are always ready for use, this is not of much moment. One great advantage to the practitioner will be the doing away with all dishes, acids, etc. The two bottles always stand ready, and when necessary the sputum can be examined while the patient is in your office. To emphasize the quickness of the process, the whole formula can be stated in four lines.

1. Pour your fuchsine solution on prepared cover-glass.
2. Heat and then allow to cool.
3. Pour off solution and pour on methylene-blue solution.
4. Pour, wash this off, dry, and mount in water.

HOW A LONDON SURGEON WAS COMPLIMENTED.—The *Pall Mall Gazette* says: "There is a story going about so good that it ought to be made public, and so improbable that it must be true. A very eminent London surgeon—one of the lights of the profession—the other day observed a gentleman fall in the street. He went to his aid, and found he had broken his leg. It was only a simple fracture, but the man was badly hurt. The surgeon used his umbrella as a splint, and with his own and borrowed handkerchiefs bandaged the limb tightly, put the patient in a cab, and drove to the nearest hospital. There they were received by a young surgeon or his *locum tenens*. 'You've bandaged this very well,' said the hospital surgeon. 'You flatter me,' said the great gun. 'Not at all,' said the other, 'I suppose you have been attending an ambulance class. They say a little learning is a dangerous thing, but the little you've learnt you've put to good account. I can't give you your umbrella now, but if you leave your address it shall be sent home.' 'I had best give you my card,' said the eminent surgeon. And he did so."

TREATMENT OF ZONA.—Dr. Guibout recommends flexible collodion as an application in the treatment of herpes zoster. The advantages are that it has a local anæsthetic action, that it exerts a uniform pressure on the lesions, and that it forms an impermeable covering which protects them from the action of the air.

INTRA-PERITONEAL RUPTURE OF THE URINARY BLADDER—LAPAROTOMY—DEATH.

By JOHN YOUNG BROWN, M.D.,

HENDERSON, KY.

In April, 1887, I was called to see A. W——, the messenger stating that he had fallen while drunk and severely injured himself. When I arrived at the house I succeeded in obtaining the following history. Patient had been drinking heavily, and, while returning home on the evening of his accident in a state of intoxication, had fallen, striking himself over the hypogastrium on the corner of a door-step. I learned from his brother that he had been suffering for some time with gonorrhœa, and had experienced great difficulty, in the three or four days prior to his accident, in making water. Upon examination, I found patient in a condition of collapse, vomiting at intervals, and complaining of severe pain in lower abdominal region and intense desire to urinate. Just before my arrival he had passed about ℥ ij. of bloody urine. He showed no sign of external injury, and thorough examination of pelvic bones revealed no fracture. Morph. and atropia sulph. was administered hypodermically, and a catheter was with some difficulty introduced, which resulted in the withdrawal of ℥ jss. of bloody urine. Rectal examination succeeded in obtaining a very decided "snow-ball crepitation" from posterior surface of bladder, suggestive of hæmatoma. Intra-peritoneal rupture of the bladder being suspected, I called in consultation Dr. Arch Dixon. Catheter was again introduced, but with almost negative result, as only a few drops of blood came away. The diagnosis still being doubtful, the rectum was dilated with a Petersen rubber colpeurynter, and the bladder was then slowly injected with warm Thiersch's solution (℥ xxx.), after the method of Weir (New York Medical Record, January 22, 1887). There was no sign indicative of bladder distention, and only a third of the fluid injected was drawn off. The diagnosis of intra-peritoneal rupture being almost conclusive, immediate laparotomy was proposed. I explained to the patient's family his condition, the object of operation proposed, and its probable result, giving of course a grave prognosis. I could not get their consent for an immediate operation, but succeeded in gaining a promise that, if the patient was no better on the morning of the following day, operation would be permitted. A soft rubber catheter was tied in the bladder, and morph. and whiskey was ordered to be administered during the night. I left my patient even worse than I had found him, and with very little hope that he would live through the night. All preparations were made for the operation, and the next morning, twenty-two hours after injury, I visited patient and prepared to operate. He had spent a restless night, and gave evidence of profound shock complicated by alcoholic depression. Morph. and brandy was administered, and patient was put under the influence of ether.

The field of operation was prepared in the usual way. The abdomen was scrubbed with soap and carbolized water, shaved, and washed with 1 to 2,000 bichloride solution. Incision in the median line was made, and the peritoneal cavity opened. A quantity of blood-stained fluid escaped from the peritoneal wound. A rent in the posterior under surface of the bladder, an inch and a half long, was discovered. The edges of the bladder wound were everted, and the mucous membrane of the viscus was clearly visible. The rent in the bladder was closed with nine carbolized silk sutures, including the peritoneal and muscular coats of viscus, after the method of Loubert. After completing the suturing of the bladder, which was accomplished with some little difficulty, the viscus was again slowly injected with Thiersch's solution. There being no discoverable leakage, the bladder to all appearances being water-tight, the peritoneal cavity was thoroughly cleansed with hot water, and the abdominal wound closed and dressed in iodoform gauze and absorbent cotton. A catheter was tied in the bladder for drainage, and patient was placed in bed. Hypodermics of brandy were given at regular intervals, and hot-water bags were placed on feet and limbs. The operation lasted an hour and ten minutes. For the first six hours patient's condition seemed slightly improved, and about ℥ jss. of almost clear urine had escaped through catheter. Patient from this time on grew gradually worse, and died sixteen hours after operation.

Autopsy.—There were no signs of peritonitis, and post-mortem injection of bladder showed an absolutely water-tight viscus. Kidneys were not examined. Patient died from shock and alcoholic depression.

Notes.—Rupture of the bladder is by no means an unusual occurrence. Prior to the introduction of the present method of suturing the bladder, accomplished by means of abdominal section, intra-peritoneal rupture was in every case fatal, and of the ninety-four cases reported by Bartel[1] there was but one (?) recovery.

With such grave statistics as the foregoing, none can question the fact that laparotomy is a justifiable operation for vesical rupture. That the operation promises a great deal, as technique and diagnostic methods improve, is established beyond question by the two successful cases reported by Sir William MacComac.[2] Since MacComac's report both Holmes and Walsham[3] have operated successfully. I am able to find in the literature but these four successful cases, although the operation has been done a number of times both in this country and abroad. However, the cases above mentioned are sufficient to set a precedent, and it is fair to conclude that, ere long, laparotomy will prove successful in the majority of cases. Diagnosis of intra-peritoneal rupture is in the major portion of cases arrived at with difficulty, and it is questionable whether it can be accurately made without exploratory laparotomy. The method proposed by Weir[4] proved very satisfactory in my case, and seems to me to be the most certain of any yet proposed. As soon as diagnosis is arrived at, operation should be made, as every moment of waiting lessens patient's chances for recovery. Shock is a prominent feature in intra-peritoneal rupture, but this is no indication for postponement, for as soon as the peritoneal cavity is opened a decided improvement is noticed in patient's condition. The suturing, with the exception of the lower stitches, is accomplished with little difficulty. When complete, the bladder should be injected to insure against leakage. In regard to drainage, I think median cystotomy and a large drainage-tube fixed in the bladder will prove a far better method than drainage through a catheter. It can be done in a short space of time, and, besides giving rest to the bladder, it affords a free outlet to the urine.

Tobacco Vertigo.—Having investigated sixty-three cases of excessive use of tobacco, Decaisne finds forty-nine to be over fifty years of age. More than half the cases presented, besides digestive derangements, alternating constipation and diarrhœa, an exaggeration of the urinary secretion and more or less abundant sweats, insomnia, and palpitation. In thirty-seven cases the smokers pursued the habit fasting, and in these vertigo was present especially in the morning. The appearance of the vertigo coincides in one-third of the cases with the suppression of the profuse sweats and marked diminution of the urinary secretion. Sometimes the vertiginous symptoms have been confounded with those due to cerebral congestion, and even to heart disease. Besides the absolute suppression of the use of tobacco, laxatives, warm baths, magnesia, and bitters are prescribed. Injections of ether subcutaneously also appeared to stop the vertigo in a few minutes. —*Lancet.*

Clinical Department.

LAPAROTOMY FOR TYPHLITIC ABSCESS—RECOVERY—WITH A REPORT OF FOUR ADDITIONAL CASES.

By C. B. KIBLER, M.D.,

CORRY, PA.

Case I.—E. S. M——, aged fourteen, came under the care of Dr. Clark, of Columbus, Pa., March 15, 1888, who gives the following history of the case: Constipation had existed for some time; there had been a slight chill; there was pain in the right inguinal region, extending into the lumbar, and shooting down into the testicle; temperature was slightly elevated; pulse accelerated only moderately, which condition changed from day to day. The pain and tenderness in the right iliac region increased, and general peritonitis ensued. He had been treated with morphine in frequent doses sufficient to control the pain; ol. terebinth. and ol. ricin., together with dry heat applied locally; liquid diet, etc. I was called on the afternoon of March 24th, by Dr. Clark, to see the patient in consultation. An aspirating needle of large size was passed into right inguinal region, and three ounces of very offensively smelling pus was removed. Laparotomy was performed the next morning at 10 A.M., when I was most ably assisted by Drs. Clark, Gilson, and Borroughs. The incision was made from just above Poupart's ligament, in the right linea semilunaris, extending upward and backward five and one-half inches, opening into an abscess-cavity from which escaped five pints of very offensive, fetid-smelling pus. The cavity was thoroughly washed out with a 1 to 1,000 sublimate solution of a temperature of 104° F. The cæcum was not to any extent involved, but in the appendix, at its distal extremity, was found an opening, through which had passed a grape-seed, which was, no doubt, the exciting cause of the perforation. Upon examination it was thought best to leave the appendix *in situ*. The wound was closed with deep silver sutures and superficial silk ones, and was dressed with iodoform and absorbent cotton. A drainage-tube of large size was left in for eight days. Castor-oil was given on the fourth day, with happy effect, and the lad has made an uninterrupted recovery.

Case II.—I was called in consultation to see D. B——, aged forty-three, male, who had been suffering for ten days with typhlitis, shown by constipation, vomiting, pain in the right iliac region, extending down into testicle, and distention and tenderness of the abdomen. Opium had been very freely given. As it was midnight and no instruments were at hand, it was thought best to wait until morning and then operate. But about 4 A.M. the abscess discharged per anum, when three pints of very offensive pus was passed; in the afternoon another discharge of about one pint occurred, and the patient fully recovered.

Case III.—In 1870 I treated E. W——, male, aged fifty-eight, for typhlitic abscess. He had great pain in the right inguinal region, extending down to the testicle and the right thigh. There was general peritonitis, with a rapid pulse, and excessive vomiting. Collapse occurred on the eighth day and death that night. No autopsy.

Case IV.—I was called to see R. B——, male, aged sixty-one. The bowels had been constipated for several days, and the man had taken compound cathartic pills (U. S. Ph.) in large doses with moderate cathartic effect. There was a chill followed by vomiting and great pain in the right inguinal region, extending upward to the axilla and downward to the testicle. The abdomen was very tender and distended. Temperature subnormal; pulse, 120, weak and thready. The patient died on the seventh day. No autopsy.

Case V.—J. D——, male, aged sixteen. The attack was ushered in with a chill. He had vomiting, a temperature of 103° F.; pulse, 126; pain and tenderness in right inguinal region, darting down into the testicle and thigh of the same side. Large doses of morphine were given, and hot applications were made. On the fifth day of his trouble I proposed to aspirate the abscess, but his parents objected to any operative procedure. After pointing out to them the danger of such delay I consented to wait until the next day; but what was my surprise, upon making my morning visit, to find that the lad had just a few minutes before evacuated three pints of very offensive-smelling pus per anum. From this time he made an uninterrupted recovery. Thus we see that it is not always possible to determine when to operate and when not to. One symptom in all the cases was well marked, *i.e.*, pain darting down into the testicle.

THE VALUE OF THE NUTRITIVE BATH AND OF INUNCTION.

By GEORGE EDW. HOPKINS, M.D.,

NEW YORK.

In the more chronic bowel-disorders, in which the child suffers through a period of several weeks, the whole alimentary tract being implicated, death finally takes place from exhaustion—essentially from starvation; for, no matter how carefully nursed and fed, the nourishment is not appropriated by the system. The blandest food acts rather as an irritant to the inflamed surfaces. The stomach itself, however, if there be no vomiting, is probably still capable of absorbing such material as requires no bowel-digestion. Here the most appropriate aliment is the whey of milk, and the white of egg thoroughly beaten with water to considerable thinness, and lightly salted. These may be given alternately. Milk itself is of doubtful utility in these cases. If not digested, it becomes only a source of irritation.

Gentle friction of the abdomen with some warm, bland oil is extremely useful. The absorbents of the skin are exceedingly active during such wasting diseases, and, if the friction be continued very gently for several minutes at different periods of the day, considerable nourishment may be thus obtained. Some oils are more appropriate than others, from being more readily absorbed.

Following each inunction, great relief is afforded by warm fomentations of camphor. Fold a light linen tissue (as a large handkerchief) three or four thicknesses, of a size to cover the whole abdomen; dip this in water warmer than the hand, wring out the drip, and, sprinkling the warm surface lightly with spirits of camphor, apply it quickly to the abdomen. Then cover all with dry flannel under the clothing. The warm, camphorized vapor has a most soothing effect

There are cases of these disorders in children in which the stomach will retain nothing. Even a teaspoonful of cold water is often rejected. Here it is manifestly impossible to do anything in the way of stomach-feeding, and we must resort to other measures. It is in these cases that *the soup bath* becomes a boon beyond all price. It not only relieves the thirst (which may be accomplished also by prolonged immersion in tepid water) but it imparts sufficient nourishment to tide the patient over the critical period. We have known a child's life most evidently saved by this simple means. Let some pieces of mutton or other meat, sufficient for making two or three gallons of good soup, be first simmered for an hour and then boiled sufficiently long to thoroughly soften and extract the juices. In skimming do not take away all the fat. This latter may be skimmed off while cooling and kept warm for inunction later. Pour the soup, when ready, into the little bath-tub, and, when sufficiently cool, immerse the child in it for a period of twenty minutes. It should, of course, have sufficient depth to cover the entire body, the head being supported by the nurse's hand. This should be repeated twice daily, the bath being rewarmed for a second use, and a fresh soup made, if possible, each day. Let the bath be followed by inunction of the entire body with the warm fat that was set aside. After two or three days, if the case improve, the stomach will begin to retain light nourishment. In the meantime, the fomentations of camphor may be continued. Attempts at nourishment by the rectum are apt to be futile in these cases, as may be readily seen.

THE USE OF ERYTHROPHLEINE AS A LOCAL ANÆSTHETIC.

By S. G. DABNEY, M.D.,

LOUISVILLE, KY.

On April 7th Professor Kastenbine, of this city, brought to my office a specimen of the new local anæsthetic erythrophleine, which he had received direct from Merck, of Darmstadt. Professor Kastenbine made a solution of a strength of a little less than one-tenth of one per cent., and of this three drops were instilled into the eye of a patient with strabismus convergens, just over the insertion of the internal rectus; the immediate effect was a slight pericorneal injection, unattended by pain. After fifteen minutes the anæsthesia was evident, though not complete. Stroking the eye, into which the erythrophleine had been dropped with a strabismus hook, was very little felt, while the same irritation to the corresponding part of the other eye was acutely felt. After half an hour's waiting the sensibility was further diminished, but not entirely abolished. At the end of one hour after the instillation the anæsthesia seemed complete, and the usual operation for internal strabismus was done; the taking up of the conjunctiva with forceps and cutting it were entirely painless, though, of course, the passage of the hook under the muscle and its pressure on the sclerotic caused some pain. Atropia had been used to paralyze the accommodation, and the pupils remained widely dilated. I did not see the patient again until the next morning, and then the insensibility had entirely disappeared.

Dr. S. P. Shroeder, of the resident staff of the Louisville City Hospital, was present, in addition to Professor Kastenbine and myself, and to each of us there was no doubt that the anæsthesia was at least as perfect as that induced by cocaine.

From the result of this experiment it seems likely that the great irritation reported from the application of erythrophleine, and its failure to produce anæsthesia, are probably to be attributed to the impurity of the preparation which was used.

TREATMENT OF CARBUNCLE WITH CARBOLIC ACID.

By W. FRANKLIN CHAPPELL, M.D., M.R.C.S. Eng.,

NEW YORK.

Carbolic acid is constantly recommended for injection in the treatment of this disease, and, no doubt, is of some service; but the difficulty of introducing a needle into the hardened tissue and then discharging some of the contents of the syringe is so great that it is almost impossible to carry out the treatment satisfactorily. During the past four years I have employed carbolic acid locally in this disease, in many cases with most gratifying results. In the early stage, when the carbuncle is small and symptoms not severe, a daily application, for two or three days, of a few drops of pure carbolic acid will arrest the process and produce a speedy resolution of the part.

When the disease has progressed further and infiltrated the surrounding tissue, and caused a gangrenous condition of the skin at numerous points, a more radical application is necessary. Vaseline is applied to the skin surrounding the sloughing centre, to prevent an unnecessary action of the acid, should any escape. With a small-pointed dropper I introduce one or two drops of pure carbolic acid into each suppurating point, and allow it to percolate into the tissue beneath. After each opening has been treated in this manner the intervening tissue is painted with the acid, and vaseline and protective gauze applied over the whole. Within twenty-four hours there will be a marked diminution in the local and general symptoms. The following day the same procedure will be carried out, and also each succeeding day, for three or four days, depending on the size of the carbuncle; by the fifth or seventh day the central slough can be picked out, as the superficial tissue will have been destroyed, and an antiseptic dressing may then be applied. Resolution goes on rapidly, and two or three dressings are all that will be necessary. Since I have employed this method of treatment, I have aborted every case that presented early, and the more advanced cases respond immediately to the treatment, and, in place of growing daily more formidable, will lessen in size, hardness, etc., from the first application of the acid.

An opportunity has not presented to employ the treatment in those severe cases where the necrosing process has extended many inches beneath the skin, and I would hesitate to apply pure acid to such a large surface at one time, but think satisfactory results would be obtained by treating a small surface each day, or by employing a weak solution of the acid. Viewed from my present experience, I think these severe cases will be unknown in the future, if the disease is seen early and the acid applied.

AN INTERESTING CASE OF DEPRESSED FRACTURE OF THE FRONTAL BONE.

By FREDERIC A. RICE, M.D.,

BRIDGEPORT, CONN.

Charles B——, native of England, aged twenty-eight, spoon-maker. On December 22, 1887, while under the influence of liquor, he was injured by the cars. He was taken to the Bridgeport Hospital, where he was found to have a crushed foot, a depressed fracture of the skull over the right eye, several scalp-wounds, and two or three severe contusions. As he did not present the symptoms of severe compression, the fractured skull was not operated on at this time, but the foot was amputated (Syme's amputation), and the other wounds dressed, all antiseptically, and all healed readily. It is his mental condition that we are particularly interested in.

From the time of the injury he lay in a state of low muttering delirium, unconscious of his surroundings, totally devoid of intelligence, reason, and memory, with no self-control, no appreciation of his natural wants, very little tendency to sleep, and great restlessness. It was necessary to fasten him into his bed.

There was no paralysis, but vision was lost in the right eye. An examination of the eye by Dr. F. M. Wilson, ophthalmologist to the Bridgeport Hospital, showed diminished arteries and enlarged veins, suggesting to him probable fracture of the orbital plate of the frontal bone with pressure in the orbit from the bone, or from infiltration of blood.

On February 1, 1888, when my term of service as visiting surgeon began, there had been no improvement in his symptoms. His only hope seemed to lie in an operation to relieve the pressure on the brain. Accordingly, on February 8th, seven weeks after his injury, assisted by Dr. C. C. Godfrey, of the visiting staff, and Drs. De Wolfe and Osborne, of the house staff, I removed the depressed bone. The skull at the seat of fracture was exposed by a large crucial incision, and, as we intended to replace the pieces of bone in the wound, the periosteum was raised with the flaps. On exposing the skull it was found that the fracture, which was comminuted and impacted, reached from near the median line of the frontal bone outward a little beyond the temporal ridge, and from the supraorbital arch upward for about an inch, enclosing a piece of bone about two inches long and one inch wide, which was depressed about the thickness of the bone, or about one-third of an inch.

Two buttons of bone were removed at the edge of the fracture with the trephine, and an attempt was made to lift the fragment; but, owing to the lapse of time since the injury, it could not be done. Then with the chisel and rongeur the fragment was entirely removed in small pieces. All the pieces of bone were kept carefully on warm carbolized gauze, and enough of them to loosely close the opening were laid back on the dura mater, the periosteum was stitched over them with catgut, a rubber drainage-tube was introduced, and the flaps were closed with catgut sutures. The wound was dressed with bichloride gauze and cotton, and was not disturbed for a week, when the tube was removed and a new dressing applied; at the end of another week the wound was healed. At the end of three weeks the fragments of bone were sufficiently united to give some firmness to the skin over the opening.

For the first two or three days after the operation there was no apparent improvement in the patient's mental condition; then his intellect began to gradually shake off the lethargy and brighten; his delirium subsided, he became more quiet, began to recognize his surroundings, and to appreciate his conditions and wants, and his memory began to return; in short, in three weeks from the time of the operation he was completely recovered, except that there has been no return of vision in the right eye. A recent examination by Dr. Wilson shows marked atrophy of the optic nerve.

ANEURISM OF THE THORACIC AORTA.

By HERMAN C. GARDINIER, M.D.,

TROY, N. Y.

E. E——, aged forty-seven, a freight-handler; was formerly addicted to the use of spirits, but of late has been strictly temperate; denies syphilis, and never had rheumatism. Prior to October 26, 1885, he was in perfect health. This was an unusually busy day, and he had been lifting very heavy packages, and while in the act of lifting he felt a sharp, shooting pain in the præcordial region and through the left shoulder, and suddenly exclaimed, "Something has given way." He fell backward in a faint, and when he came too, found himself in bed. The pain lasted for sixteen days, when he was able to resume work. He had had ever since that time great pain in the back, which he described as a constant boring sensation in the mid-dorsal region. He slept in a semiprone position on account of dyspnœa. He complained of weakness in the legs from the knees down, which gradually grew worse, and he shuffled his feet in walking.

Physical examination: Veins of forehead and thorax prominent; jugular and subclavian veins on left side full and distended; veins of arms prominent; marked pulsation of axillary, brachial, and ulnar arteries; distinct epigastric pulsation; thrill felt in both supraclavicular spaces near the sternal junction of clavicle; liver dulness normal; lungs emphysematous; dulness in right infraclavicular and axillary regions, possibly due to thickened pleura; good vesicular murmur posteriorly over left lung, much feebler and more distant over the right side; præcordial dulness an inch outside nipple line; the apex beat was felt in sixth intercostal space and outside the nipple line; at the apex was a double bruit, soft and see-saw in character, and low in pitch; the first sound was hardly perceptible at the apex; a rough systolic murmur was heard in the left carotid artery; a double harsh murmur was heard which had its maximum intensity at the right second intercostal space; the patellar tendon reflex was exaggerated; there was paresis in both legs; the pupils were minutely contracted; but there was no change in the voice, no dysphagia, and no evident thoracic tumor or localized pulsation could be made out.

The above symptoms, especially the paresis in the legs and great backache, together with the physical signs, led me to diagnose an aneurism of the descending portion of the thoracic aorta eroding the bodies of the vertebræ. I saw the patient a number of times after this examination, and there was no appreciable change in the physical signs, save an increased weakness in the limbs, with more marked exaggeration of the tendon reflexes. Patient died rather suddenly, December 25th.

Autopsy, eight hours after death: Left lung free from adhesions, emphysematous; lower lobe full of blood-stained serum; right lung universally adherent, pleura much thickened, lung full of serum. Pericardium non-adherent, sac contained about two drachms of serum; heart very large. An aneurism involving the transverse and descending portion of the arch of the aorta was found, the lower portion of which was adherent to the bodies of two mid-dorsal vertebræ, which were eroded down to the membranes of the cord. The heart and aneurism together weighed thirty-two ounces. Aortic valves were incompetent, a little thickened, and the orifice was much dilated. The orifices of the coronary arteries were calcareous. The left ventricle was dilated and its wall was about nine lines thick. The mitral orifice permitted the passage of four finger-tips, and the valve was thickened; the walls of the right ventricle were thinned, and its cavity was dilated.

POISONING BY CHLORATE OF POTASH.

By HORACE G. HILL, M.D.,

PHILADELPHIA, PA.

Lydia M——, a precocious little brunette, four years of age, about 10 o'clock on the morning of March 19th discovered in a closet a half-filled bottle of compressed tablets of chlorate of potash, and immediately conceived the idea of playing doctor with her two-year-old brother. The boy was doctor and the girl patient. With commendable care the doctor saw that the patient actually swallowed each dose that he ordered, and sometimes, by way of encouragement, took a tablet himself. The little girl is unusually intelligent for her years, and from her straightforward account it is probable that she ate at least two-thirds of the quantity, and possibly more. No scattered tablets could be found, and only one remained in the bottle. It is estimated, after a careful comparison with other bottles of the same size, and after weighing the tablets, that she must have taken at least eighty grains. The mother noticed at dinner that her appetite was poor, but thought nothing of this fact at the time. Early in the afternoon she began to complain of headache, which rapidly increased in severity, and was accompanied by nausea. By supper-time she was quite feverish, unable to eat, and extremely listless. High temperature, persistent nausea, great restlessness, hallucinations, and the voiding of a quantity of urine much above the normal were the prominent symptoms during the night. Unfortunately she was not seen at the worst, so that the maximum temperature and pulse rate cannot be stated. Toward morning there was a marked improvement, but upon attempting to dress her after breakfast she was found to be too weak to stand. Marked pallor was observed at this time, and continued for several days; but at the end of three days she had regained her usual condition, and now, after two weeks, seems as well as ever. The effect of the drug on the child's complexion is worthy of notice. Previously the skin had appeared quite muddy; but on convalescence it became unusually clear and transparent, and this transparency still continues. In fact, the mother asked whether chlorate of potash could not be utilized as a cosmetic. The boy was affected with similar symptoms, but in a much less marked degree.

Carbonate of Lithium is best administered, according to Liebreich, in highly charged selters or soda water. One grain of lithium, mixed with fifteen grains of sugar, will dissolve readily in a wineglassful of carbonated water.

Progress of Medical Science.

"Vaginal Pressure" in Chronic Pelvic Disease.—"Vaginal pressure" in the treatment of chronic pelvic disease was introduced by Dr. Taliaferro, of Georgia, in 1878. This original pressure was obtained by tampons of cotton, wool, and other substances, plain and medicated, and it has been brought to more perfection of method and detail by Drs. Engelmann, Wylie, and others. In the *American Journal of Obstetrics* will be found a complete exposition of this method of treatment. The procedure is safe; it affords immediate comfort; its effects are mild and continuous; rest is given the pelvic viscera; the treatment is clean and antiseptic, and all the pelvic viscera are influenced. The tampon acts as a support to hold in place the uterus or other of the pelvic viscera, and as a compressor; it acts as a stimulant to the tissues; it is a splint to steady the parts and to give rest; it cleanses and renders them aseptic by absorbing the discharges, keeping the vaginal walls dry and clean, and it can be made the carrier of remedial agents by enclosing the remedy within it, or by using a medicated cotton covering over the elastic body of the tampon. Well-prepared sheep's wool, fine, white, and clean, makes the best supporting tampon. Its use should be continuous, or almost so, and hence it should be renewed every second or third day.

Large Doses of Creosote in Pulmonary Phthisis.—Dr. Bogdanovitch has published some personal observations on the therapeutic value of creosote in phthisis. The writer, who has been suffering from pulmonary and laryngeal tuberculosis for about two years, had tried the drug on himself in small doses (half a grain four or five times a day) some time ago, but without appreciable benefit. After perusal of the observations of Sommerbrodt and Guttmann, however, he again began to take creosote in gradually increasing large doses, beginning with four grains a day, and reaching, in about two months, a daily dose of forty-four grains. There took place, fairly rapidly, an unmistakable and permanent improvement in his symptoms. Fever disappeared in a week; expectoration, cough, and dyspnœa steadily decreased to a considerable degree; laryngeal spasm, which had formerly occurred once or twice every month, ceased altogether. As regards the objective signs, however, there was only some diminution of dulness over a certain area, with complete disappearance of fine crepitant râles. As to tubercle bacilli in the sputum, they remained just as numerous as before the creosote treatment. The latter has lasted in all four months, during which period not less than four ounces and two drachms of pure creosote have been ingested. The drug must be taken in doses of about five grains four times daily, in the form of capsules (filled up *ex tempore*), after meals. With regard to disagreeable after-effects, Dr. Bogdanovitch observed in himself, when, by way of experiment, he took as much as twelve grains at a time, or twenty grains in the course of an hour, only giddiness, cardiac palpitation, small and accelerated pulse, general weakness, pallor, and anxiety; but all these toxic phenomena disappeared spontaneously and completely in about half an hour or an hour. On an empty stomach, however, he experienced epigastric uneasiness and pain even from small doses. Dr. Bogdanovitch resumed of late the use of creosote in order to study the effect of a six months' course. Dr. Hermann Sahli's paper on "Guaiacol as a Substitute for Creosote" seems to be unknown to him.—*The British Medical Journal.*

Laparotomy for Dilatation of the Colon.—A remarkable case of fecal accumulation is reported by Dr. Worrall. A girl, aged fourteen, was brought to the hospital suffering from an enlargement of the abdomen, which had been gradually increasing for two months (*The British Medical Journal*). The patient had not had any previous illness, and her mother thought her bowels were not regular. On examination, a solid tumor, neither painful nor tender, was found to fill the whole abdomen, except portions of the left hypochondriac and left lumbar regions, having its greatest prominence to the left of the umbilicus. The tumor was hard, nodulated, and irregular. It seemed to touch the liver above and dip into the pelvis below, being bounded laterally to all appearances by the colon. The tumor could be moved slightly in every direction. A day or two after admission, although the bowels were moved several times daily, a laxative powder and an enema were given prior to examination under chloroform. As the rectum was found to be still blocked with fæces, more aperients were ordered, and for the next ten days there was diarrhœa with numerous horribly offensive stools. The temperature averaged 101° F. It was decided to perform an exploratory laparotomy. On opening the abdomen what looked like an enormous cyst, fluid above and solid below, was seen, which, on being opened, was discovered to be the ascending colon enormously hypertrophied and dilated. The wound in the colon was sutured, and the abdominal incision closed. The youthful patient was discharged quite well on the fourteenth day after the operation.

Photoxyline as a Surgical Dressing.—The Paris correspondent of the *British Medical Journal* states that M. Von Wahl has lately tried substituting photoxyline, which is used in photography, for collodion in surgical operations. He employs a five per cent. solution mixed with equal portions of alcohol and ether. His experiments showed that photoxyline has the following advantages: It adheres more closely to the skin than collodion; it is absolutely impermeable, and is not deteriorated by washing or by prolonged contact with other fluids; it exercises a uniform compression on the tissues. It can, therefore, be strongly recommended in the case of slight surgical operations, when the patient is not obliged to lie up and a voluminous antiseptic dressing is most inconvenient; as in plastic operations on the face, and in those performed in the region of the genital organs in male patients (radical operations for hernia, hydrocele, castration, etc.). In these cases a thin layer of cotton-wool, free from all greasy principles and saturated with photoxyline, is applied to the wound and fixed by means of sutures and court-plaster after bleeding has stopped. This layer will resist the dissolving action of any foreign fluids for eight or ten days. The uniform pressure it exercises renders drainage superfluous. In the case of children, where it is almost impossible to prevent the contact of the dressings with the urine, photoxyline will be found especially valuable. In laparotomy this form of dressing will suffice by itself, and will protect the abdominal wound in the most efficient manner.

Acute Infectious Pharyngitis.—The above term, which should be supplemented by the word "primary," is used by Professor Senator to indicate a rare, and "perhaps always fatal," form of pharyngitis, not hitherto described in text-books of medicine. Two examples had occurred within the last few months, and a study of similar cases had revealed three more as having occurred within the last twelve years. In all these cases, reported at a meeting of the Berlin Medical Society, the disease affected previously healthy persons, without any apparent cause, and ran an acute course, ending in death in a few days. It began with cervical pains and dysphagia, accompanied by fever, often moderate; then followed hoarseness, or loss of voice, and dyspnœa; finally, the sensorium was affected, and death quickly ensued. The chief anatomical sign found *post mortem* was diffuse purulent infiltration of the deeper tissues of the pharyngeal mucous membrane, the inflammation extending to the trachea and glands of the neck, and secondarily to other parts, especially the gastric mucous membrane. Senator is of opinion that many cases hitherto regarded as examples of acute œdema of the larynx are in reality cases of the above disease.

Notably in a case of Cruveilhier's the pharynx was affected for a day or two before the larynx. The very rare "typical œdematous laryngitis," mentioned by Sir Morell Mackenzie as of septic origin, is also claimed as in all probability affording an example of the above diseases. The spleen was generally enlarged in Senator's case, and the kidneys, as a rule, showed parenchymatous inflammation. A peculiar exanthem appeared in one case. The blood removed both before and after death had been carefully examined, but no specific micro-organisms had revealed themselves in attempted cultivations, injections of which, as also of fresh blood, had been harmless in rabbits. The streptococcus of Friedländer (erysipelas coccus) was certainly absent. In the discussion which followed, Dr. Guttman argued that the cases were probably erysipelatous in spite of the above fact. Virchow leaned to Guttman's opinion, but also described other pharyngeal diseases which might mislead, especially metastatic abscesses in puerperal fever, suppurative pharyngitis accompanying acute gastritis, and, in one case, mediastinitis. But Senator urged in his reply that there was no abscess in any of his cases, but a diffuse purulent infiltration always beginning in the pharynx. The cause was absolutely unknown to him at present, but the system was very rapidly affected in a characteristic manner, and tracheotomy was of no avail. He had no doubt that a study of the subject, as revealed in hospital records, would reveal numerous examples of this disease overlooked under the title of "acute œdema of the larynx."—*British Medical Journal.*

THE CHANGES OF THE SPINAL CORD AFTER TEMPORARY OCCLUSION OF THE ABDOMINAL AORTA.—The Vienna correspondent of the *Medical Press* writes as follows concerning this subject: "At a meeting of the Verein deutscher Aertze, in Prague, Dr. Singer read a paper in which he said that he had imitated the experiments of Ehrlich and Brieger on the changes of the spinal cord after one hour's occlusion of the abdominal aorta (Stenson's experiment), for testing the results which had been obtained by those authors. The results at which Dr. Singer had arrived were the following: Twenty-four hours after compression of the abdominal aorta granular degeneration of the multipolar ganglion cells occurred, but no other change in the white and gray matter could be proved. After the lapse of eight days the cells of the anterior horns (cornua anteriora), as well as the plexus of the fibres of the anterior horns, had disappeared, and the secondary degeneration as above mentioned became more distinct. The funiculi posteriores, the spinal ganglia, and the posterior roots remained normal. After four weeks, shrinking of the whole transverse section of the gray matter, total degeneration of the anterior roots, and secondary degeneration of the whole transverse section of the 'funiculi anteriores,' except a narrow zone on the interior surface of these funiculi, and the posterior periphery of the lateral funiculi, supervened. Both these zones, however, were not to be identified with those regions which had been described by Ehrlich and Brieger. The complete disappearance of the anterior roots and the fibrillar plexus of the cornua anteriores made it possible to prosecute the course of the posterior roots in the gray matter with a particular facility."

THE TREATMENT OF URETHRAL STRICTURE BY RAPID DILATATION.—At a recent meeting of the Leeds and West Riding Medico-chirurgical Society (*The British Medical Journal*), Mr. Mayo Robson remarked that the rapid dilatation of stricture by means of Lister's graduated metal bougies—either used immediately, dilating at once up to No. 13 or 14, or, if the smallest metal instrument could not be passed, employing the same method after a fine filiform bougie had been left in for forty-eight hours—was in his experience a safe and efficient method of treatment. In some cases he had injected a solution of cocaine into the urethra before dilating, but in only one instance had he employed a general anæsthetic. In two cases of extreme distention of the bladder, where no instrument could be passed, the bladder had been aspirated several times, and then it had been possible to pass a fine bougie and to dilate. Mr. Robson related selections from fifty difficult cases thus treated, and remarked that if this method were adopted, cutting operations would be required but very occasionally—that is, internal urethrotomy in very resistant strictures, and external in cases of extensive fistulæ, or abscess, or extravasation. He always advised his patients to pass a No. 9 or 10 elastic bougie once a week. He had treated many other cases than those related, but had never seen any serious symptoms follow.

THE THERAPEUTIC PROPERTIES OF BROMIDE OF IRON.—Dr. Heequet states that bromide of iron possesses in the highest degree all the renovating properties of ferruginous medicines, and exercises, besides, a powerful sedative action upon the nervous system, diminishing, like other bromides, the after-sensibility. Hence it becomes a valuable remedy in various forms of anæmia, as it calms without depressing, and invigorates without excitement. From the year 1869 to 1887 Dr. Heequet has prescribed the bromide of iron in chlorosis, chloro-anæmia, leucorrhœa, amenorrhœa, and hysteria, with favorable results. In conjunction with Dr. Vacossin, the author had observed beneficial results from the use of this medicine in diseases of the heart, in phthisis, diabetes, and epilepsy. Its beneficial influence over spermatorrhœa is also affirmed by the author.—*L'Union Médicale.*

REMOVAL OF A PORTION OF THE LIVER.—Langenbuch has reported the successful removal of a constricted portion of the liver weighing about a pound (*The American Journal of the Medical Sciences*). Owing to its hinglike attachment to the body of the gland, and the congestive hyperplasia due to impeded circulation, it was both heavy and movable, causing intolerable distress, especially during the dorsal decubitus. The diagnosis was made by exploratory incision. The attachment was ligated in sections and the constricted portion removed. Symptoms of internal hemorrhage occurring the same evening, the abdominal cavity was reopened, the bleeding checked, the blood removed by sponging, and the wound closed. Healing was prompt, but ascites developed shortly, accompanied by some general œdema. The abdomen was twice tapped, and the patient fully recovered without further mishap. Langenbuch holds this to be the first case in which a large portion of the human liver has been removed by excision.

THE LEADING OPHTHALMOLOGISTS OF PARIS are all, with one exception, foreigners. Dr. Abadie is a Frenchman, Dr. Panas a Greek, Landolt a Swiss, Galeazowski a Pole, De Welcker a German, and Meyer a German. Landolt is the only one who, in operating for cataract, still uses iridectomy. Dr. L. is in the habit of occasionally making preparatory iridectomy for the extraction of cataract, and in cases of long duration frequently operates when the patient has considerable vision. The old idea of waiting until the patient is blind before the operation is made is about exploded. Dr. De Welcker operates by electric light. Dr. Panas always washes out the anterior chamber with a borated solution after extracting cataract. He makes the extraction without iridectomy and with most beautiful results, making, perhaps, the prettiest operation of extraction of any man that can be witnessed in all Europe, this being his particular *forte* as operator. Prof. Panas is the only oculist who holds a public clinique, his being a government institution, although all the other oculists have students following them, and the advantages with them are equally good as at the Hôtel Dieu.

PROFESSOR MÜNTER, upon the strength of his personal experience, recommends a daily excursion of three or four hours' duration upon the water as affording a remedy of the greatest value in certain cases of asthma. He regards it as very useful also in anæmia, and remarks upon the longevity and excellent health of seafaring people as confirmatory of his experience.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 9, 1888.

THE DOCTORS' MONTH.

THE month of June appears to be a particular favorite with doctors, or, more especially, with doctors' conventions. A third or more of our State Societies meet at this delectable time. The late Mr. William Cullen Bryant wanted to die, or at least to be buried, which would amount to the same thing, in June. Perhaps it may be some subtle instinct that June is a good month to die in which leads doctors to leave their patients and hurry away to the scientific convivialities of their annual State Society meetings. Or June may be perhaps for other reasons looked upon as a pre-eminently medical month. The sun is at that time leaving the obstetrically interesting sign of the Twins, and entering that permanent field of medical investigation, the Cancer. Besides this, our own Mugwump poet has said that,

> "Then heaven tries the earth if it be in tune,
> And over it softly her warm ear lays;"

thus performing the strictly technical and medical act of auscultation, and antedating Louis and Läennec by thousands of years.

Decidedly reason, astronomy, poetry, and custom make June the doctors' month. We trust that, in grateful recognition of the fact, this favored subdivision of time will treat the coming doctors' conventions with copious drafts of sunshine, together with soft and perfumed breezes, tempered to the point which promotes appetite and renders the assuaging of thirst with innocuous drinks a rational pleasure.

TRANSPLANTATION OF A NERVE FROM THE RABBIT TO MAN.

A PRELIMINARY account of the novel operation of transplanting a nerve from a rabbit to a man has been given by the Vienna correspondent of the *British Medical Journal.* The operation was done by Dr. Gersung, an assistant of Professor Billroth's, and the patient is Professor Fleischl. Sixteen years ago Professor Fleischl received a wound at a post-mortem examination, which resulted in inflammation of the right hand and arm, and, finally, gangrene of the terminal phalanx of the thumb, which was amputated. Neuromata developed, attended with great pain, and the branches of the radial and median nerves were successively resected until the thumb and nearly all the fore-finger became anæsthetic. New neuromata continued to develop, however, and the pains became so intense that the patient wished to undergo another operation, in order to procure at least temporary relief. Accordingly, the following operation was performed: On March 4th the patient was put under the influence of chloroform, and the neuroma, which was situated behind the volar carpal ligament, was excised, the nerve being cut through behind the neuroma. The peripheral nerve-stumps of the two digital branches above mentioned were then sought for. A rabbit was now killed, and as long a piece as possible of the sciatic nerve of the animal, with the two branches into which it becomes divided, was dissected from it (the animal still presenting voluntary contractions). The sciatic nerve was afterward inserted into the space between the central stump of the median nerve and its digital branches; the central end of the sciatic nerve was sutured to the connective tissue, which covered the median nerve, and the two branches were sutured to the digital branches of the median nerve—the portion of nerve, measuring about six centimètres, which was deficient being thus made up. After the operation severe pain persisted for some hours, but then entirely subsided. Healing took place by first intention. As two months have now elapsed since the date of operation and the pain has not returned, it may be hoped that the favorable result will become a permanent one. Sensibility, moreover, is becoming re-established in the part. Dr. Gersung has postponed the publication of the case, because he wished to observe whether complete sensibility would return; he hopes with confidence that this will be the case. The ultimate result will be awaited with great interest; for, if it be as favorable as now appears probable, Dr. Gersung's recommendation that the operation should be given an extended trial will doubtless be widely acted on.

DERMEPENTHESIS.

DR. G. F. CADOGAN-MASTERMAN thinks that the term human or animal skin-grafting is somewhat awkward, and suggests as a substitute the pentasyllabic mononym given above. Without attempting to discuss the question whether "dermepenthesis" is a term of greater vocal elegance or of more agreeable prosodical possibilities than "skin-grafting," we can at least speak with praise of a very interesting and practical contribution to this subject which Dr. Cadogan-Masterman has made. He says: "It is to be regretted that the practice of skin-grafting, which gives such excellent results, should be attended with so many inconveniences. The donor, as I have often personally experienced, finds the momentary 'snip rather painful, and the little sores are some days in healing. A sensitive patient does not like giving the grafts himself, and his friends, although eager enough to provide them the first time, are seldom willing to repeat the donation, and there is the danger, if alien skin be used, of conveying local or even constitutional disease. And if the surface to be covered be large, the process is extremely tedious, and often disappointing. Frog's skin has been used as a substitute, but these amphibia are so repulsive to most people, and especially so to women and children, that after two trials I gave it up, and the more so because it utterly failed in both cases, and sought for some other source which would avoid the inconveniences, and yet be generally available, and I believe I have found it in the skin of the rabbit."

He takes the skin of a young wild rabbit, using that from the abdomen. The animal is killed by a sharp blow on the back of the neck, and the necessary graft immediately dissected off and applied to the antiseptically clean granulating surface. He uses pieces as large as two inches in diameter. These are removed by sterilized instruments.

Not a moment must be lost in the transferrence, and the graft must be kept moist, not sodden, thoroughly warm, under gentle, equable pressure, and not disturbed for forty-eight hours. There is no need to remove the fur, it comes away in every case within a few days.

Dr. Masterman does not think that the skin is actually engrafted. The skin proper obviously does not grow, though possibly the fascia beneath may do so. But in some way it promotes the development of the granulation cells into integument.

The advantages of the method as summed up are:

"That the patient is spared all pain himself as well as seeing it inflicted upon others; that in place of minute centres of new growth being established, surfaces up to at least two inches in diameter may be covered at once; that in the case of burns this rapid tegumentation not only prevents much suffering, but greatly reduces the probability of subsequent contraction; that alien skin may be unhesitatingly employed; and that the duration of healing is reduced to a minimum."

As young wild rabbits are not so plentiful in America as in Stourport, where Dr. Masterman lives, our readers may be interested in the utilization of the rooster in the process of dermepenthesis. Dr. F. Altramirano, a Mexican physician, mentions (*El Observado Médico-Lancet*) a case in which he successfully employed the gills of a cock. Fragments were cut off, these were split, divided into ten pieces, and the raw surfaces applied to a freshened portion of the ulcer. A carbolized dressing was then bandaged on, the whole being constantly moistened. On the third day, on the dressing being removed, all the ten fragments were found organically adherent. A number of new grafts were then applied, cut from the comb, the gills, and the skin of the back of a chicken. None of these were successful. The cock's gills were again resorted to, and four more fragments successfully grafted. A fresh set of grafts were prepared from this source; but all the cellular tissue was cut or scraped away, in some cases little but the epidermis being left, in others the edges being bevelled, so that the epidermis was in direct contact with the raw surface of the ulcer. This set of grafts proved very unsuccessful, so that Dr. Altramirano was led to the conclusion that no advantage is gained by applying the epidermic layer immediately in contact with the surface of the ulcer.

WHAT IS THE BEST THERMOMETER FOR THE GENERAL PRACTITIONER TO USE?

If there are one hundred thousand physicians in this country, there are certainly twice that number of clinical thermometers, taking into account the number of anxious mothers and introspective adults who have been indiscreetly supplied with them. The story that the clinical thermometer tells, therefore, ought to be a correct one; but if we may judge by some recent experiments made by Dr. Makrocki, of Potsdam (*Deut. Mediz.-Zeitung*), this is not often the case.

There have lately come into use two new forms of thermometers, the minute-thermometer, a very small instrument modelled after the ordinary maximal thermometer, and the avitreous thermometer, an instrument made like a watch, very sensitive to temperature changes, but not maximal in its readings.

Dr. Makrocki made many experiments upon healthy and febrile patients with these new, as well as with the older, forms of thermometers. He found that the so-called minute-thermometers never in a single instance reached their maximum in one minute, and not often in two minutes.

The avitreous thermometer in six minutes only reached its maximum twice in twenty trials. The errors in the two thermometers ranged between one-fourth and one-third of a degree Centigrade. Tests made with ordinary clinical thermometers, and with ordinary non-maximal thermometers, showed similar, but slighter, degrees of variation.

Dr. Makrocki thinks, therefore, that the best thermometer for common use is the ordinary one, or preferably a thermometer without a maximal index, but long enough (fifteen centimetres) for the reading to be taken while the instrument is still under the arm or in the mouth.

THE LEGAL RESPONSIBILITY OF THE OBSTETRICIAN FOR PUERPERAL FEVER.

Times have greatly changed since Dr. Oliver Wendell Holmes wrote his classical essays, in order to prove to a doubting profession that puerperal fever was in any way a contagious disease. This question has not only long been settled, but a sentiment is growing that midwives and the general practitioner should be held in a measure legally responsible for the occurrence of this complication. At a recent meeting of the Chicago Medico-legal Society this subject was broached, and an editorial in the *Journal of the American Medical Association* discusses it further, giving at the same time the recently expressed views of Professor H. Fritsch, as to puerperal infection *in foro*.

The tendency of modern pathology is to look upon puerperal fever as puerperal sepsis. There is by no means, however, a general agreement that infection enters always by the genital tract, and never by the lungs or digestive organs.

The innumerable accidents and complications of the puerperal state, to say nothing of the peculiar susceptibility, or lack of vital resistance, which makes some patients so easily succumb to even feeble pathogenic agents, must be taken into account. And it can be only in very rare cases that the responsibility of infection can be directly traced to the midwife. Professor Fritsch says:

"A question that the judge addresses to the expert is the following: 'Do the operations or the omissions of the midwife stand in causal relation to the death of this puerpera?'" This question cannot be answered simply by 'yes' or 'no.' At most, only the scientific conviction can be expressed that a causal nexus does exist. But the expert is never in a position to swear that except for the operations or the omissions of the midwife the life of the puerpera would without doubt have been preserved. Fatal peritonitis may occur in consequence of the rupture of a pyosalpinx during the course of an otherwise normal labor; the possibility of purely accidental infection, in which the midwife plays no part, must be admitted.

"The modality of the infection must be clearly established before the causal nexus can be looked upon as demonstrated. To establish the modality of infection, three data are to be supplied:

"1. The source of the material of infection must be made clear.

"2. The omission of disinfection must be demonstrated.

"3. Any cause of death other than the puerperal disease must be eliminated."

This is a fair statement of the case, and it is evident that the fixation of legal responsibility upon a midwife or physician will, for a long time, be a difficult thing to do. An agitation of the subject, however, will be of benefit in calling attention to the importance of observing the ordinary methods of disinfection in the lying-in room, and especially of the importance of personal disinfection while attending other patients who have infectious or suppurative disorders.

News of the Week.

An English Contemporary in the *Medical Press* publishes the following: "The death is announced of Dr. Clemens Lozier, of the New York Medical College and Hospital for Women, from *angina pectoris*. The deceased lady was the pioneer of the movement in America for the medical education of women. She practised medicine for over thirty years, and had been Dean of the New York College ever since its establishment in 1863." Our esteemed contemporary will probably shiver in a double-leaded rigor when it learns that Dr. Lozier was a rank homœopath, and with all respect to her memory a demoralizer rather than pioneer in sound medical education. It is part of history that the Drs. Blackwell were the pioneers of medical education for women in this country.

Militant Gynecologists and Orthopedic Surgeons.—"Can anybody explain," says the *Medical Press*, "why gynecologists should be such irascible people when they meet together to discuss points in practice? That they are so is a matter which was forced on our notice at a recent meeting. Judging from the experience of that evening, it is quite sufficient for one man to allege highly successful results from one method of treatment for the others to fall upon him and lapidate him without even allowing him the time to mutter a benediction on his persecutors. There are one or two recognized camps the individual members of which insist upon, and receive—but not always—a certain amount of consideration. Outside these charmed circles all is assumed to be vanity. Mr. Tait only forced his way into the cœnaculum, thanks to a certain vigor in his build and arguments, backed up by a voice which it would be difficult to effectually muffle. Others, of less aggressive material, collapse, subside, and are seen no more for a time. The only other people whose ways resemble those of the gynecologists to whom we allude, are the orthopedic surgeons. They, too, think nothing of accusing rivals of 'faking' their photographs or drawings to exaggerate the importance of the results obtained, and the differences of opinion among them are at least as marked and irreconcilable as among the women doctors." We would venture to suggest that the trouble lies in the fact that the special societies are young and the specialty immature. Quarrelling is a characteristic of callowness and imperfect evolution. It is the experience in this country that after a time special societies become as peaceful as those of a general character.

E Pluribus Unum.—The four medical schools of Minneapolis and St. Paul have been discontinued, and in their place is the Medical Department of the Minnesota State University. The course is a three years one, and is graded. There is a regular and a homœopathic faculty.

Menstruation has been observed to occur in a child one year old, in a child of four, and recently Kornfeld reports a case of menstruation in a child of three who had been subjected to sexual irritation.

Statue to a Medical Legislator.—At Milan, on the 30th ult., a statue in bronze, the work of the great sculptor Vela, was erected to Agostino Bertani, who, as surgeon, medical legislator, and patriot, deserved so well of Italy. Statesmen of every political school were present at the ceremony, and the Syndic of Milan, the Senator Negri, dwelt in a strain of hearty, unaffected eloquence on the high aims, the pure philanthropy, and the scientific grasp of the man they commemorated. To sacrifice a brilliant professional career in order to act as medical head to the army of independence under Garibaldi; to keep abreast of the professional scholarship and practice of the day while tending the sick and wounded of the Italian "Risorgimento;" to dedicate the evening of a stormy existence to the moulding and maturing of a great body of sanitary regulations tending to lighten and lengthen the lives which he had helped to civic freedom—such was the peculiar merit of Bertani. He lived just long enough to complete his Hygienic Code, bequeathing the exposition and indication of its articles to his political friends; and it was a happy coincidence that scarcely was Vela's fine presentation of his Stoic figure and keenly intellectual countenance uncovered when the Italian Senate put the seal of its approval to his "Codice Sanitário."—*The Lancet.*

Papillomatous Tumor of the Bladder and the Electro-cystoscope.—Dr. F. N. Otis, of this city, writes: "The 'Case of Papillomatous Tumor of the Bladder,' published in The Medical Record of May 5, 1888, I claimed as the first of the kind in this country detected by means of the electro-cystoscope and confirmed through subsequent operation. Until seeing the note of Dr. Otis K. Newell, of Boston, in your last issue, I was not aware that he had previously published an account of two similar cases in the *Boston Medical and Surgical Journal* of December 1, 1877. I hasten to concede to Dr. Newell, with my congratulations, the priority, to whom it thus clearly is shown to belong." Bearing upon the same subject, we call attention to the following note from Dr. Clinton Cushing, of San Francisco: "In The Medical Record of May 5th, Dr. Otis reports a case of papilloma of the bladder diagnosed by means of the cystoscope, and thinks it the first case of the kind so diagnosed in this country." Dr. Cushing sends us a copy of the *Pacific Medical and Surgical Journal*, showing that this was first done in San Francisco, last November.

Pancreatic Diabetes. — M. Lancereaux describes cases in which occur sudden loss of strength, great thirst, polyphagia, wasting, and loss of sexual desire, with at first diurnal and later also nocturnal polyuria. Phthisis developed at the apices of both lungs. Death occurred with a low axillary temperature. Nothing was found at the necropsy except atrophy of the pancreas; the pancreatic duct was narrowed in one part of its length, and completely obliterated at another; there were no calculi, and the organ weighed thirty-five grammes. Violent epigastric pain is remarked upon; the polyuria is nearly always related to the quantity of liquid ingested. Atrophy of the pancreas has been described as due to sclerosis, calculi, obliteration of the duct, and steatosis. Some observers have thought that destruction of the pancreas is perhaps a cause of diabetes. Several types of diabetes are recognized by Lancereaux: pancreatic or lean diabetes, with very rapid progress; fatty or constitutional diabetes, which is more commonly hereditary, has a slow course, and presents no pancreatic lesions; traumatic or nervous diabetes, due to shock of some kind, and generally slight and curable. We do not give these views because we endorse them, but because they are suggestive speculations.—*The Lancet.*

New York Post-graduate Medical School and Hospital.—At the meeting of the Board of Trustees of the New York Post-graduate Medical School, held on Monday, May 28, 1888, the following appointments were made in the Faculty: Abraham Jacobi, M.D., Professor of Diseases of Children; Robert F. Weir, M.D., Professor of Clinical Surgery; Peter A. Callan, M.D., Professor of Diseases of the Eye; L. Bolton Bangs, M.D., Professor of Diseases of the Genito-urinary Organs and Venereal Diseases; Joseph E. Winters, M.D., Professor of Diseases of Children; O. B. Douglass, M.D., Professor of Diseases of the Nose and Throat. Dr. William A. Hammond, being about to remove to Washington, has resigned his position as Professor of Mental and Nervous Diseases. Dr. Hammond was one of the founders of the school.

June Meetings of the State Medical Societies. –The Indiana State Medical Society meets at Indianapolis June 5th and 6th. The Delaware Medical Society, at Georgetown, June 8th. The Massachusetts State Society, at Boston, June 12th. The Michigan Medical Society, at Detroit, June 14th. The Oregon Medical Society, at Portland, June 12th. The Ohio State Society, at Columbus, June 13th. The Colorado State Society, at Colorado Springs, June 19th. The New Hampshire State Society, at Concord, June 19th. The Vermont State Society, at St. Alban's, June 28th. The Maine Medical Association holds its thirty-sixth annual meeting at Portland, June 12th, 13th, and 14th.

The American Physiological Society, which holds its first annual meeting in Washington, D. C., September 18th, 19th, and 20th, announces the following preliminary list of papers: "On the Therapeutic and Forensic Aspects of Hypnotism," Dr. G. Stanley Hall; "On Enzymes comparable with Papain, found in Certain Fruits of Temperate Climates," Dr. G. L. Goodale; "On the Knee-jerk Phenomena," Dr. H. P. Bowditch; "On the Nature of the Knee-jerk," Dr. W. P. Lombard; "On the Effects of Varying Rates of Nerve Stimulation upon the Character of Muscular Movements," Dr. H. P. Bowditch; "Growth and Death," Dr. C. S. Minot; "The Cells of the Cortex Cerebri," Dr. C. S. Minot; "The Uterus during Gestation," Dr. C. S. Minot; "On the Temperature Limits of the Vitality of the Mammalian Heart," Dr. H. N. Martin; "Histological Changes Produced in Ganglion Cells by Stimulation," Dr. H. H. Donaldson; "On Fever," Dr. Isaac Ott; "On the Distribution of Bacteria in Drinking-waters and Public Buildings," Dr. W. T. Sedgwick; "The Origin and Regeneration of Blood-corpuscles," Dr. W. H. Howell; "On Certain Ptomaïnes," Dr. W. C. Vaughan; "On the Physiological Action of the Uranium Salts," Dr. R. H. Chittenden; "On Myoscin and Certain of its Decomposition Products," Dr. R. H. Chittenden; "On the Influence of Acetanilide or Antifebrin on Proteid Metabolism," Dr. R. H. Chittenden.

A British Laryngological and Rhinological Society is to be organized on June 29th. Great Britain now has obstetrical, gynecological, ophthalmological, neurological, and medico-psychological societies, and the work of specialization progresses.

The Late Dr. Edward S. Dunster.—At the last meeting of the Wayne County Medical Society the following preamble and resolutions were adopted:

Whereas, It has pleased Almighty God to remove from his earthly sphere our worthy companion and professional brother, Dr. Edward S. Dunster, of Ann Arbor, Mich.; therefore, be it

Resolved, That we as a society tender to his grief-stricken family our heartfelt sympathies. To the profession before whom he has appeared so eloquent in address, logical in his reasoning, honest in his opinions, which he maintained with his utmost power, and, above all, his loyalty to the profession he so dearly loved, and for whose best interests he so long and sedulously labored, we can only say that the loss of one so eminent can illy be told in resolutions or words; in this the heart alone can speak. In obedience to the Almighty power that rules the destinies of men, that can build up or cast down, that can give or take away, we bow in humble submission about the bier of our departed friend, fellow-member, and professional brother. Be it further

Resolved, That our Secretary transmit a copy of these resolutions to the press and to the family.

Wm. Brodie, M.D.,
Hal C. Wyman, M.D.,
C. Henri Leonard, M.D.,
Committee.

Office of the Secretary of the Wayne County Medical Society, Detroit, May 4, 1888.

The Recent Death of a Harvard Student from Opium-smoking has created a sensation, not only because of the tragic death of a promising young man, but because it reveals the fact that opium-smoking is one of the dissipations which certain fast young men consider it smart to indulge in.

Dr. A. R. Davidson, of Buffalo, N. Y., Professor of Medical Chemistry in the Niagara University, died on May 25th, after a brief illness. Dr. Davidson was forty-three years of age at the time of his death. He had been one of the editors of the *Buffalo Medical and Surgical Journal*, and was widely esteemed, and successful as an analyst, chemist, and practising physician.

Merck's Amorphous Sulphate of Hyoscyamine.—Dr. Charles Rice, of this city, writes: "On page 608 of last Medical Record, in a note by Dr. W. A. McCorn on the use of hyoscyamine, there occurs an error, probably by the compositor misreading the author's manuscript. It should read 'Merck's amorphous sulphate,' instead of 'Ulrich's amorphous sulphate.' The reason why Merck's *amorphous* sulphate is preferred is this, that a large percentage of this consists of hyoscine, the real hypnotic of hyoscyamus, which it is a difficult and expensive operation to isolate in a pure state."

The Rabbit Plague.—It is reported that the conference upon the means of dealing with the rabbit plague in Australia has resulted in the selection of an island where M. Pasteur's and other methods of extirpation will be put to a thorough trial.

An Antidote to Serpent Venom.—Dr. H. C. Yarrow, Curator of Reptiles in the National Museum, announces (*Forest and Stream*, May 10th, *et seq.*) that he has discovered the fluid extract of jaborandi to be an efficient antidote to serpent venom. This applies to mammals, but not to birds.

The Texas Medical College, first organized in 1864, reorganized in 1873, and deceased, it was supposed, in 1881, has been revived at Galveston. A Board of Trustees and a Medical Faculty have been created, a building secured, some money subscribed, and the institution will open in the fall. We do not recognize any familiar names among the Faculty, and infer that the new college is the result of local enterprise. It is not endowed; and we can but regard it as a serious injury to the medical profession to have more unendowed medical colleges organized in this country.

Prescriptions in the Vernacular.—In illustration of the French practice of not writing prescriptions in Latin, the *Journal of the American Medical Association* says: "In one of Simon's prescriptions for laryngismus stridulus we find *eau de tilleul* called for. *Tilleul* means a lime-tree, a linden. Turning to this word in a medical dictionary, we are referred to *tilia*, and find that the flowers of *Tilia Europœa* 'have been supposed to possess anodyne and anti-spasmodic virtues.' Under *Tilia Americana* we find that 'a mucilage, prepared by macerating the inner bark in cold water, has been applied in burns.' Thus far we have no clew as to what *eau de tilleul* is. Again, we find a prescription calling for *carbonato de litina*; we can only guess that carbonate of lithium is what is wanted, for the best Spanish dictionary does not give *litina*."

The Law Regarding Puerperal Fever and Midwives, enacted in Saxony three years ago, is as follows: "When a lying-in woman delivered by a midwife becomes the subject of puerperal fever, the midwife is not permitted to attend the sick woman any longer. Neither can another midwife undertake the further care of the woman sick with puerperal fever. The midwife is not permitted to undertake the management of another case of labor within a period of five days, or even longer, reckoned by the district physician from the day of her last visit to the sick woman." The last sentence is a faulty one, since it is not time, but proper modes of disinfection, which render safe a person who has come in contact with contagious disease.

Lanolin in Cuts and Burns.—A recent article in the *Pharmaceutische Rundschau* (No. 3, March, 1888) states that experience has shown that lanolin is an excellent dressing for cuts and burns. Professor B. Fränkel finds that it prevents the formation of scabs, and that burns under this treatment do not desquamate so much as under most others. In cases where it is desired to irrigate a wound in order to reduce heat and irritation, lanolin may still be applied, as it is not readily washed away. If a small wound is immediately dressed with this ointment basis, hemorrhage is stopped.—*British Med. Journal.*

Capital Punishment by Electricity.—The bill to abolish the gallows and to execute criminals by electricity has become a law, and New York will have the credit, if it is a credit, of being the first government to inflict capital punishment in this way.

Reviews and Notices of Books.

The Year-book of Treatment for 1887. A Critical Review for Practitioners of Medicine and Surgery. Philadelphia: Lea Brothers & Co. 1888.

This "Year-book" for 1887 is published after the same plan as those of preceding years, a plan which leaves little room for improvement. The vast amount of medical literature for the year ending September 30, 1887, has been thoroughly sifted, the essential facts being grouped together in a series of short notices covering all the more important points in practical medicine and surgery. The book is a very useful and handy manual of reference for anyone desirous of keeping posted on all the advances made in the healing art.

The New York Medical Journal Visiting List and Complete Pocket Account Book. New York: D. Appleton & Co.

The second part of the title of this book explains more fully its nature than does the first. It is not, strictly speaking, a visiting list, as that term is usually employed, since there is no room in it for a memorandum of engagements. It is rather an account book, and a very handy and convenient one it appears to be. Each page contains the accounts of three persons, showing the number of visits made and the amount charged or collected during the month. The same space will serve for the records for several months, when the visits are few and were not made on the same days in the different months. The book is not dated, and it may therefore be begun at any time.

Thérapeutique Chirurgicale Contemporaine. Par Albert Heydenreich. Paris: G. Steinheil. 1888. Tome II., pp. 304.

This work gives a critical summary of modern surgical therapeutics, including the technique of antisepsis and of difficult and capital operations.

Leçons de Clinique Chirurgicale, fontes à l'Hôpital Saint-André (de Bordeaux). Par le Dr. André Boursier, Professeur Agrégé à la Faculté de Médecine, chargé du Cours de Clinique Chirurgicale; Chirurgien des Hôpitaux. Paris: G. Steinheil. 1887.

This work comprises a series of fifteen lectures delivered by Dr. Boursier in the surgical clinic of the Hospital of Saint-André at Bordeaux. The subjects treated of are miscellaneous in character, but are well selected, and the book shows evidence of careful revision. The author's method of dealing with his material is felicitous, and those who had the pleasure of listening to him are to be congratulated on their good fortune. The book is both readable and instructive.

Forms of Systematically Recording Observations and Results of Treatment in Affections of the Throat and Nose, including adjacent associated areas. By Scanes Spicer, M.D., B. Sc. Lond. London: H. K. Lewis, 1887.

These are blank forms for recording the histories of cases of aural, nasal, and laryngeal affections. They are especially useful for students who have not yet learned what to look for and how to conduct their examinations. Outline-drawings of the parts, for the purpose of sketching the lesions, accompany the blanks.

Similia Similibus Curantur? Addressed to the Medical Profession. By Charles S. Mack, M.D. Boston: Otis Clapp & Son. 1888.

In this brochure the author discusses the question of homœopathic treatment of disease, and whether similars do or do not cure. He comes to the conclusion that there is no positive proof that similars do cure or that they do not cure, yet he is disposed to try to cure with them. We wish him all success in his attempts to cure, by whatever means.

Revue des Sciences Médicales en France et à l'Étranger, Recueil trimestriel analytique, critique et bibliographique. Dirigée par G. Hayen. Paris: G. Masson.

This well-known review, now in its sixteenth year, needs no special commendation from us. It gives one of the best and most complete summaries of medical progress.

Jahresberichte über die Fortschritte der Anatomie und Physiologie. Herausgegeben von Dr. L. Hermann und Dr. G. Schwalbe. Band L. Literatur 1886. I. Abtheilung. Anatomie in Entwickelungsgeschichte. Leipzic: Verlag von F. C. Vogel. 1887.

The present volume contains six hundred and fifty pages, and comprises, in a convenient form, a critical review of the anatomical and embryological literature of 1886.

Index of Materia Medica, with Prescription Writing, including Practical Exercises. By Charles H. May, M.D., and Charles F. Mason, M.D. New York: William Wood & Co. 1887.

This is one of the series of convenient little volumes which are intended to refresh the memories of students, and which are often of convenience to full-fledged doctors, known as Wood's Pocket Manuals. It maintains the standard of excellence set by its predecessors.

A Manual of Medical Jurisprudence, for the Use of Students at Law and of Medicine. By Marshall D. Ewell, M.D., LL.D., Professor Common Law in Union College Law School, Chicago. 12mo, pp. 396. Boston: Little, Brown & Co. 1887.

It is very properly said by the distinguished author of this manual that most works in medical jurisprudence are very voluminous, and are not adapted for the study of the abstract principles of the science. To supply this need, he has striven to enumerate certain general facts which serve as a very useful and practical groundwork for future and more elaborate study. It will be found to be a very useful and instructive handbook for the lawyer as well as the doctor. The subjects are well arranged and the salient points of each are well brought out.

The Transactions of the Academy of Medicine in Ireland. Vol. V. Edited by William Thomson, M.A., F.R.C.S. 8vo, pp. 366. Dublin: Fannin & Co. 1887.

The Transactions of this Society are models of their kind, and prove the members to be active, practical, progressive, and working men. The present volume contains papers of value in every department of medicine and surgery, and forms a valuable addition to the working library of every student and practitioner. The typographical execution is everything that could be desired, while the illustrations, of which there are several, are excellent.

Treatment of Hemorrhoids by Injection of Carbolic Acid. By Silas T. Yount, M.D., etc. 12mo, pp. 102. Lafayette, Ind.: The Echo Music Co. 1888.

This manual is rather a prolix setting forth of the advantages of treating piles in the manner indicated. It contains nothing of practical value which is not found in any system of surgery. The author has invented a "speculum" for rectal diseases, and this small volume is a "second degree" in the well-trodden specialist path.

Chronic Metritis. By Georges Apostoli, M.D., Paris. 12mo, pp. 117. Detroit: George S. Davis. 1888.

The full title is, "On a New Treatment of Chronic Metritis, and especially of Endometritis with Intra-uterine Chemical Galvano-cauterizations." The translator is Dr. A. Lapthorn Smith, of London, whose work has been creditably done. So much has been written, in medical journals of recent date, of Apostoli's views that we need not repeat them here. The whole subject is well summarized in these hundred pages.

Mechanical Massage. By George H. Taylor, M.D., New York. 12mo, pp. 173. New York: John B. Alden. 1888.

Mechanical massage is defined as "the principles and practice of remedial treatment by imparted motion." The author sets forth in plain language the advantages of the so-called "movement cure." He has practised it successfully in this city for many years, and his opinions are entitled to weight. After a general discussion of this therapeutic method, he speaks of its applicability to indigestion, nervous disorders, paralysis, rheumatism, and renal diseases. His ideas on "The Delusion of Tonics," as the heading of the last chapter reads, are open to criticism, but, on the whole, the book is sound in doctrine.

Obstetric Synopsis. By John S. Stewart, M.D., of the Medico-chirurgical Society of Philadelphia. 12mo, pp. 202. Philadelphia: F. A. Davis. 1888.

This volume is a condensation of the lectures delivered at the above institution in this department of medical study. It is not as large or as comprehensive as the well-known "King's Manual," but is clear and concise. The chapter on the development of the ovum is especially satisfactory. The Appendix contains the obstetrical nomenclature adopted by the Ninth International Congress. The judicious use of faced type for headings, and italics for important statements, gives the book a pleasing typographical appearance.

On the Wasting Diseases of Infants and Children. By Eustace Smith, M.D. Pp. 380. Fifth edition. Philadelphia: P. Blakiston, Son & Co. 1888.

Dr. Smith's valuable work is so well known to the profession that the fifth edition needs no commendatory remarks. The text has been somewhat revised, and some additions made, but the work is essentially the same as in the previous edition.

DISEASES OF THE SKIN: A Manual for Practitioners and Students. By W. ALLAN JAMIESON, M.D., Physician to Royal Infirmary, Edinburgh, etc. 8vo, pp. 646. Philadelphia: J. B. Lippincott Co. 1888.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. By JOHN V. SHOEMAKER, M.D., Philadelphia. 8vo, pp. 633. New York: D. Appleton & Co. 1888.

THESE two companion volumes are able exponents of the present accepted knowledge of skin disease. The former is essentially an English work, confined to the treatment of cutaneous diseases endemic in the British isles. The latter is written from a somewhat more general stand-point, and bears intrinsic evidence of greater originality, especially in the line of therapeutics. Both are illustrated by wood-cuts and colored plates of a high order. In both the general classification of Hebra is adopted, though with some minor differences. We shall not be accused of over-patriotic zeal if we recommend Dr. Shoemaker's book as the preferable one for American physicians and students. His style is simplicity itself, and therein has he scored his greatest success over other authors we might name. An extensive formulary is embraced in the sixty pages following the text proper. As might be expected, the oleates receive prominent mention throughout the volume, which is the recorded experience of a practical-minded American physician.

RECTAL AND ANAL SURGERY, WITH A DESCRIPTION OF THE SECRET METHODS OF THE ITINERANTS. By E. WYLLIS ANDREWS, A.M., M.D. Pp. 111. Chicago: W. T. Keener. 1888.

To answer the questions, What are the best methods of diagnosis and treatment of rectal diseases, and what are the secret methods of the itinerants, and what is their value? is the object of the writer of this work. Many will differ from him, in some respects, in the way he answers the first question, while the attention which he has paid to the investigations of the "quack pill-doctors," and his *exposé* of them, and remarks upon them, will awaken general interest, and make the book one which the physician will be glad to see.

THE HYGIENE OF THE SKIN; OR, THE ART OF PREVENTING SKIN DISEASES. By A. RAVOGLI, M.D. Pp. 400. Cincinnati: Central Medical Publishing Co. 1888.

THIS book occupies the medium ground between a wholly scientific and professional work, and one addressed to the laity. It tends to bring together the specialist in dermatology and the adept in cosmetics. It blends with its descriptions of the skin historical details, practical directions, ancient receipts for hair-growing—withal a curious medley of information, some of which is interesting, some of which is practical, and much which is of doubtful utility.

DOCTOR AND PATIENT. By S. WEIR MITCHELL, M.D., LL.D. Pp. 177. Philadelphia: J. B. Lippincott Co. 1888.

DR. MITCHELL'S facile pen imparts an interest to whatever he may write, whether it relates to purely scientific subjects, or to fiction, or, as in this case, to the discussion of semi-medical subjects, which invite alike the attention of the physician and of the patient. These essays are, perhaps, more suggestive to the patient than to the doctor, yet they contain for the latter many valuable suggestions, which, if heeded, will go far to ensure the success which the writer of them has attained.

SIX HUNDRED MEDICAL DON'TS; OR, THE PHYSICIAN'S UTILITY ENHANCED. By FRED. C. VALENTINE, M.D. Pp. 144. New York: G. W. Dillingham. 1887.

WITH "Six Hundred Don'ts" to write, of all kinds and descriptions, it would not be surprising if the writer failed in some of them, in the words of the title of the book, "to enhance the physician's utility." In fact, it would be a brave doctor who would dare encounter a patient armed with these "Six Hundred Don'ts;" nevertheless, he might find in this armamentarium of prohibitions not a few which would prove useful to him in meeting that class of patients who are ready to pester the life out of a physician with questions as to what is healthy and what is not. In short, the book may prove no mean weapon both of offence and defence.

THE RECTUM AND ANUS: THEIR DISEASES AND TREATMENT. By CHARLES B. BALL, F.R.C.S.I. With fifty-four illustrations and four colored plates. Pp. 409. Philadelphia: Lea Brothers & Co.

THE writer has added a valuable text-book to those which have been written upon this subject. It is terse, well expressed, and practical. Not much can be said in praise of the lithographic plates with which the work is illustrated.

CLASSIFIED AND DESCRIPTIVE DIRECTORY TO THE CHARITABLE AND BENEFICENT INSTITUTIONS OF THE CITY OF NEW YORK. Pp. 227. New York: The Charity Organization Society. 1887.

THIS Directory, admirably executed and carried out, will prove of great use to the profession, since the doctor is constantly coming in contact with the poor and the afflicted, and constantly called upon to face the problem of relief for them.

A MANUAL OF THE PHYSICAL DIAGNOSIS OF THORACIC DISEASES. By E. DARWIN HUDSON, JR., A.M., M.D. William Wood & Co. 1887.

THIS work is the outcome of a smaller manual published by the author in 1885. At the time we paid a high compliment to the thoroughness and literary skill shown in the minor work. Of the present, we can only say that it has been amplified and more fully illustrated, and now most satisfactorily meets the needs of students and physicians who desire a complete modern manual of physical diagnosis.

The lamented author died before his work had been finally revised; but this revision has been satisfactorily performed by Dr. Laurence Johnson.

THE RULES OF ASEPTIC AND ANTISEPTIC SURGERY. A Practical Treatise for the Use of Students and the General Practitioner. By ARPAD G. GERSTER, M.D. New York: D. Appleton & Co. 1888.

THIS work is a timely publication that cannot fail to interest every surgeon who wishes reliable information on the subjects of antisepsis and asepsis. The author does not pretend to have written a systematic treatise on operative surgery. Nevertheless, all the more important surgical procedures are dealt with in such a way as to leave little room for improvement.

Two defects mar this otherwise highly instructive treatise. One is the unnecessary multiplication of cases from the author's own practice. The other is the introduction of photographic illustrations that are, for the most part, very imperfect as regards clearness of detail. The question whether the work would not have been improved had these illustrations been omitted, is one that naturally suggests itself. This is all the more to be regretted, as in all other respects the mechanical execution of the volume is simply excellent.

The author has wisely refrained from discussing the relative merits of the various systems of antisepticism now in vogue. He gives those methods with which he is personally most familiar, and at all times endeavors to inculcate principles, rather than to harp upon special methods of wound treatment.

In presenting to the English reader a complete, coherent, and often very enthusiastic account of modern aseptic surgery, the author has unquestionably earned the thanks of the profession. We predict for this volume a generous and appreciative reception by those to whom it is addressed.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Thirty-ninth Annual Meeting, held in Cincinnati, O., May 8, 9, 10, *and* 11.

(Concluded from page 619.)

SECTION ON OBSTETRICS.

THURSDAY, MAY 10TH—THIRD DAY.

DR. WILLIAM H. WATHEN, of Louisville, read a paper on

ABDOMINAL SECTION IN EXTRA-UTERINE PREGNANCY.

Ten years ago he read a paper before the Kentucky State Medical Society on Cæsarean section, in which he suggested that the sac in extra-uterine pregnancy might be separated from the attachments by the proper use of ligatures. He had not then seen a similar suggestion, though Kiewisch and Stephen Rodgers had probably recommended this many years before. The idea was severely criticised at the time. The objection that the placenta might be so attached to the abdominal walls, intestines, or other structures as to prevent its removal, is more theoretical than practical; for such attachments are by no means constantly found in operations or post-mortem examinations. However, if the sac cannot be removed without incurring the risk of fatal hemorrhage, it may be left behind and partially resected and stitched in the abdominal wound with a drainage-tube in the lower angle of the incision. Nearly all gynecologists recommend the destruction of the fœtus with electricity before the fifth month, and before there has been a rupture of the vessels of the sac.

DR. C. R. REED, of Middleport, O., presented a communication entitled

THE EARLY REMOVAL OF ABDOMINAL CYSTIC TUMORS.

He reported a number of cases which were not unique, yet they taught the utter inefficiency of medication, and that the removal of the uterine tumor is the only hope of safety. Tapping raised false hopes, afforded but temporary relief, and complicated the operation for removal. A woman who has an abdominal cystic tumor should be told by her physician that its early removal, while it is small and free from complications, is devoid of danger, and she should be warned of the danger of delay.

DR. RUFUS B. HALL, of Cincinnati, read a paper entitled

A PLEA FOR EARLY OPERATIVE INTERFERENCE IN CASES OF OBSCURE PELVIC PAIN

and recurrent attacks of pelvic inflammation in women. The speaker thought that, in these cases, the ovaries were at fault, and he urged their removal early, before secondary changes had occurred to render the operation less beneficial in its secondary results. The speaker referred constantly to the operation as

TAIT'S OPERATION,

which was the occasion, later, of some strong words from Dr. Battey.

DR. WILLIAM H. MYERS, of Fort Wayne, Ind., read a paper on

THE TREATMENT OF PERITONITIS.

Is acute peritonitis ever idiopathic? Is it a symptom or a disease? Is it always septic? Again, Does the treatment properly belong to the physician or the surgeon? It is of primary importance that in every case the etiology be settled at the earliest possible moment. The blow must be struck simultaneously with the advent of the enemy, the only hope of rescue being the sudden arrest of the disease. The speaker believed that acute peritonitis is always septic and never idiopathic, and he thought that the treatment should be modified in accordance with these views. He quoted the published opinion of those who advocated the giving of salines rather than opium in the treatment of peritonitis, and related a case in which he had employed this means with excellent results. He then referred to the operative treatment of peritoneal inflammation, quoting Lawson Tait, who has written: "I have deliberately come to the conclusion that it is an act of almost criminal omission to allow a case of peritonitis to die without abdominal section."

DR. A. M. JOHNSON, of Danville, Ky., presented a communication on

THE MANAGEMENT OF EXTRA-UTERINE PREGNANCY.

After reviewing briefly the methods formerly employed, he discussed those most commonly recommended at the present day, viz., electricity and abdominal section, the former of which he considered thoroughly irrational and dangerous. Electricity, he said, will kill the fœtus, but it will not destroy the placenta, which will continue to secrete amniotic fluid until the period of nine months has expired. He thought that all cases of extra-uterine pregnancy, up to the fifth month, should be treated by laparotomy, and quoted from a letter of Lawson Tait, who said: "Electrolysis has already been exploded in our country, and has subsided into its original position of

RAMPANT QUACKERY."

The speaker thought that the proper management of extra-uterine pregnancy was still in its infancy, but he hoped that the electric battery would soon be banished from this field.

PROFESSOR WILLIAM GOODELL, of Philadelphia, said he was in accord with the substance of the papers just read, except that he thought they were too sweeping. He often gave saline cathartics with good results, but he would not keep opium from all cases, for he thought such practice was nothing less than cruel in some. He did not believe in operating on every case where there might be a little pus in the ovary. Cases which he had condemned to the knife had gone to Weir Mitchell, and had been cured. In a woman whose trouble is gonorrhœal in its origin he would recommend the removal of the tube and its ovaries. In syphilis he would wait and give constitutional treatment, for it is the local explosion of a constitutional disease.

DOES THE REMOVAL OF THE OVARIES AND TUBES UNSEX A WOMAN?

It does not absolutely. For one to two years the sexual feeling generally remains intact. The speaker had seen it even increase for a time, though this was only temporary.

DR. S. C. GORDON, of Maine, criticised Dr. Goodell's remarks. The latter, he said, would operate in cases of gonorrhœal disease of the ovaries, but how could any man say whether the ovarian disease was specific or not? He thought the advisability of an operation should be decided by a study of the symptoms. He claimed to have the second recorded case of operation for tubal pregnancy, Dr. Johnson having had the first.

DR. ROBERT BATTEY, of Rome, Ga., said that Dr. Hall, a youthful member of the profession, seemed to know nothing about American work, to judge from his constant use of the term "Tait's operation." Way back in 1872, before the time of Dr. Hall, there was

A HUMBLE AMERICAN SURGEON

who suggested and described this operation. The reader of the paper had spoken of Tait's struggles in introducing the operation, but older members of the Association would remember the struggles of the speaker to win the sanction of the profession for his operation. He was advocating the method for years, and not a word escaped from Tait until 1879. Should the mere say-so of Tait be accepted when he asserted that he had *thought* of the operation? Why should Mr. Tait come in at the end of the fox-hunt and claim the brush?

Dr. Battey said that he had modestly, too modestly, remained quiet, and had allowed Mr. Tait to talk about "his operation," for he despised this

MISERABLE QUIBBLING ABOUT PRIORITY;

but when an American, in the American Medical Association, and in his presence, talked so glibly about Tait's operation, it was a little more than an ordinary mortal could stand. He then referred to his experience in London in 1881.

"MAY GOD FORGIVE MR. LAWSON TAIT,"

he said, "and preserve me from falling into his ways."

Dr. Howard A. Kelley, of Philadelphia, said that many of the younger members of the profession were not acquainted with the claims of Dr. Battey. Tait, he said, had shown gross ignorance of American practice, and he believed also that his diagnoses of extra uterine pregnancy were jumped at. He had heard that Tait thrust his hand into the abdomen, pulled out something, said "extra-uterine pregnancy," and threw it away.

Dr. Johnson had seen Tait operate in five cases of extra-uterine pregnancy, and in all the specimens were carefully examined by all who wished to do so and were capable.

Dr. Hall said that he had not expected or desired to raise a question of priority, but whatever Dr. Battey might say, it was impossible to go back of the returns. Tait said he performed his first operation in February, 1872, Battey claimed to have done his in August, 1872. Tait was certainly the first man to recommend the operation for chronic inflammation or abscess in the ovary.

DR. BATTEY'S CAUSTIC REMARKS

had created a laugh, but the fact remained that Tait stood head and shoulders above all other operators in this particular field.

Dr. Ely Van de Warker, of Syracuse, N. Y., delivered the President's Address, the subject of which was

HOW GYNECOLOGY IS TAUGHT.

The address was an able exposition of imperfections in this teaching. Of 109 medical schools—those only which are approved of by the Illinois State Board of Health—in only 56 did the catalogues announce it as separately taught; in 14 the chairs of diseases of women and children were united; 32 announced a professor or a lecturer of gynecology; 10 made no mention of thesubject; 1 announced forty-four lectures on gynecology; in 66 the subject was taught by the professor of obstetrics or not at all. The "commercial spirit" is largely responsible for the imperfections of medical teaching. The attempted reform by the adoption of the graded system had not proven a success. The introduction of a graded system, with recitations from the text-books, was the adoption of a method which is already abandoned by progressive educators.

Dr. E. W. Cushing, of Boston, exhibited a number of microphotographs, illustrative of the pathological changes occurring in

ENDOMETRITIS, ADENOMA, AND CARCINOMA CORPORIS UTERI.

Dr. Nathan Bozeman, of New York, read a paper on

RENAL TENESMUS,

and its treatment by kolpo-uretero-cystotomy. By renal tenesmus he meant a violent and painful contraction of the ureter and pelvis of the kidney, the result of morbid irritability of these parts. The pain occurs in paroxysms which vary in frequency, duration, and severity. As a rule, the pain begins in one groin, and extends later to the lumbar region, being generally most severe at night and during the menstrual period. The patient awakes with an urgent desire to evacuate the bladder, and the act is followed by pain and cramps, sometimes by nausea and vomiting. He reported several cases in which he had relieved those symptoms by

KOLPO-URETERO-CYSTOTOMY

with intravaginal drainage. It was necessary to make a large opening, the diameter of a silver half-dollar, for it soon contracts down to the size of the index-finger. When the bladder is not kept completely drained, the spasm will persist, the reflux of urine into the ureters will continue, and the group of renal symptoms and complications will not be relieved. The artificial fistula must not be closed until all thickening of the vesical walls and tenderness about the urethra, bladder, and ureter have disappeared. In order to determine whether it is time to close the opening, the speaker was in the habit of introducing an intravaginal dilator, which kept the urine from flowing out through the fistula. If no distress in the bladder followed the wearing of this dilator for ten days or two weeks, he proceeded at once to close the opening. A complete cure was usually obtained only at the expiration of from six to twelve months.

CONNECTICUT STATE MEDICAL SOCIETY.

Ninety-seventh Annual Meeting, held in New Haven, May 23 and 24, 1888.

Wednesday, May 23d—First Day.

The meeting of the fellows was called to order at 3 P.M. by the President, **Dr. Francis Bacon**, of New Haven.

After the Committee on Credentials had reported, the President delivered his

ANNUAL ADDRESS

to the fellows. After welcoming those present, he spoke upon the proposed changes in the charter which had disturbed the harmony in the Society for a number of years, and expressed the hope that it would be amicably and finally settled at this meeting. More time, he said, should be given to reading papers and to scientific discussion. He also advised, as did the President of last year, that a standing committee be appointed to guard against the enactment of unjust laws by the State Legislature. It would be greatly to the benefit of the Society if the meetings were held in different cities of the State, and not confined to New Haven and Hartford, as is now the custom. It was with great reluctance that he announced that the Secretary and Treasurer both declined to hold their respective offices any longer. In conclusion, he was greatly opposed to sectional rotation in the election of Presidents of the Society. He favored the election of the man best qualified for the position, without regard to the county from whence he came.

After the President had announced the Committees, the Treasurer reported a balance on hand of $832.18.

Professor J. C. Dalton, of New York, was then elected an honorary member of the Society, and the name of Dr. Edward M. Moore, of Buffalo, was proposed. This, in accordance with a by-law, was laid over for one year.

THE ELECTION OF OFFICERS

for the ensuing year was then held, with the following result:

President—George L. Porter, M.D., of Bridgeport.

Vice-President—O. Brown, M.D., of Washington.

Treasurer—W. W. Knight, M.D., of Hartford.

Secretary—N. E. Worden, M.D., of Bridgeport.

Committee on Matters of Professional Interest—Drs. L. P. Almy, L. T. Day, and W. L. Ford.

Dissertator—P. H. Ingalls, M.D.

Delegates to the American Medical Association—Drs. J. B. Kent, C. B. Newton, E. C. Kinney, W. H. Welch, S. B. St. John, C. H. Hill, F. D. Edgerton, H. W. Buel, B. W. Munson, and F. E. Beckwith.

Delegates were also elected to attend the meetings of the State Societies of Maine, Massachusetts, New Hampshire, Vermont, Rhode Island, New York, and New Jersey.

In the evening a

MICROSCOPICAL SOIRÉE

was given by the Faculty of Medicine of the Yale Medical School, and later the members of the Society were received at the residence of Dr. Bacon, on High Street.

THURSDAY, MAY 24TH—SECOND DAY.

THE REPORT OF THE SECRETARY

was read, which showed that there had been received into the Society during the year thirty-four new members, and that there had been lost by death ten of the old members. There had been an unusual number that had left the State, and two who were dropped for non-payment of dues. The total membership at present is four hundred and ninety-four.

The President then delivered his annual

ADDRESS TO THE CONVENTION.

He began by speaking of the advances made in surgery, nervous diseases, and materia medica, and the profit which is to be derived from such advances; but there was one subject near his heart in which this State compared most unfavorably with most States, and made no progress toward improvement; this was the

RELATION OF THE INSANE TO THE LAWS OF THE STATE.

Here any man, who had the certificate of a justice that he was a "reputable physician," could commit his neighbor to confinement in a lunatic asylum. The average justice he did not think competent to determine who should pass judgment upon the sanity of his fellow-man. He recommended a competent and permanent commission to act upon all cases. He spoke sarcastically of

EMOTIONAL INSANITY,

and was thankful the courts of this State had never been disgraced by such a plea. He claimed that experts could not diagnosticate between such a case and uncontrollable anger. It was a very light opinion he held of some of the expert testimony given in the courts. After relating several cases of grave mistakes by experts, he said that he thought that society demanded that all homicidal lunatics should be confined, not for a definite period, but for life, in order that any future attacks might be guarded against.

The following delegates from other State societies were introduced and made remarks: Dr. C. A. Ray, Vermont; G. D. Colin and A. M. Smith, Massachusetts; W. H. Palmer and Charles O'Leary, Rhode Island. These were followed by reports of delegates from this Society to those of the neighboring States.

Dr. R. M. Griswold read a dissertation on the text

IN SORROW THOU SHALT BRING FORTH CHILDREN.

His argument was that man was made perfect, but with the downfall came sorrow, pain, and sickness. The obstetrician meets women diseased from the sins of their forefathers, and imperfectly formed women. After referring to the well-known regulations for the female during gestation, he spoke of the complications of labor, and the means we have for their relief. Uterine inertia was the first one we were most likely to meet in the first stage. For this he used quinine in doses of from two to five grains every twenty minutes until from three to five doses had been given. He also used ginger in the form of hot tea, and prescribed plenty of exercise. These were usually all that were required to stimulate uterine contraction. For a rigid os he used chloroform and emetics. In some cases the pain was so severe that it was impossible for the woman to help herself, and for such cases he recommended a few whiffs of chloroform at the beginning of the pain.

He concluded by speaking of the great usefulness of forceps, by the use of which we have fewer still-births and less rupture.

Dr. Douglass said that he used quinine and ginger together in cases of uterine inertia. He thought the action of quinine more certain when combined with an aromatic.

Dr. Kinney said he would never give ergot until there was no obstruction to the immediate delivery of the child. He thought we should never hesitate to use forceps when the vagina began to grow dry, or there were signs of failure upon the part of the mother.

Dr. J. M. Keniston then read a paper on

PARALDEHYDE.

He reviewed the history of the drug, and gave its chemical formula. For years a good sleep-producer, which had no disagreeable after-effects, had been sought for, and in the discovery of paraldehyde he thought we had found it. It was generally given before retiring, but he thought that it was best for the patient to get what natural sleep he could first. It could be given safely in ʒ j. doses until three doses had been given, and if no effect was felt from that quantity, it was best to try something else. Its action was quicker than chloral, and it was as safe as the bromides, as no important organ was likely to be injured by its use.

Dr. G. M. Shepherd, as Chairman of the Committee on Matters of Professional Interest, read a paper upon the

FREQUENCY OF ALBUMIN IN THE URINE OF THE HEALTHY.

That albumin is sometimes present in the urine of the healthy has been recognized for a hundred years. Usually in such cases its appearance is only temporary. The late Dr. Flint said that the presence of albumin, even with casts, was not always of grave import. The most of the paper was composed of statistics showing the percentages obtained by different observers of this occurrence.

Dr. E. F. Parsons followed with a communication entitled

ALCOHOL IN THERAPEUTICS.

He quoted scripture to show the opinions held of alcohol in the time of the ancients, and from these passages drew the conclusion that we should never hesitate to use it when demanded. He said it was a stimulant to the brain, heart, and stomach; it increases the size of the capillaries and slightly raises temperature. He asked the question, Is alcohol a food? This question he also answered by asserting that as it can take the place of food by carrying on the duties of the body, without the loss of weight, for a limited time, it is certainly a food. He concluded by saying that Dr. N. S. Davis, of this country, and Dr. B. W. Richardson, of England, were among those most opposed to the use of alcohol, and that even these gentlemen acknowledged its utility in some instances.

Dr. C. B. Newton then read a paper on

PNEUMONIA,

in which he treated of the prevention of the disease. He emphasized the desirability of maintaining a lower temperature and purer air in shops and dwelling-houses than is usual. He offered nothing new in the way of treatment.

Dr. J. K. Thacher presented a paper on

THE RELATIONS OF CARDIAC HYPERTROPHY TO NEPHRITIS.

He related the history of a boy who had scarlet fever, followed by nephritis, and this in turn by cardiac hypertrophy. From the beginning of the nephritis there was increased arterial tension. A few weeks after the nephritis disappeared, the hypertrophy also disappeared. From this and similar cases he was led to believe that cardiac hypertrophy was secondary to nephritis.

Dr. G. C. Legur, reported a case of

TYPHOID FEVER IN A CHILD,

thirteen years of age. This was a case of long-continued fever. Antipyrine was used in doses of from fifteen to twenty grains with good results. He thought antipyrine was *the* drug for the treatment of typhoid fever.

A large number of papers that had been read before the several County Societies were read by title.

The meeting adjourned at 3 P.M. The annual dinner was held at the New Haven House.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE CONTAGIOUS DISEASES ACTS IN INDIA—SIR JOSEPH FAYRER ON CHOLERA—DISCUSSION AT THE MEDICAL AND CHIRURGICAL SOCIETY ON THE VALUE OF HIGH-ALTITUDE TREATMENT IN PHTHISIS—A USEFUL DEVICE FOR A PATIENT WEARING AN ARTIFICIAL EYE—ANOTHER MEDICAL DECLARATION ON ALCOHOL.

London, May 15, 1888.

It is now about five years since the working of the Contagious Diseases Acts was suspended in this country. Although supported by the great majority of the medical profession popular feeling against them gained in strength and eventually led to the overthrow of the system of compulsorily examining women engaged in prostitution. Similar enactments have, however, continued to be in force in some parts of India up to the present time, though such abuses have crept in that the Government have now suppressed them. From accounts received here, it would seem that the system has not merely been carried out as a sanitary measure, but actually made a means of virtually legalizing prostitution. Public opinion in this country is too much against such measures to tolerate them, and it was accordingly announced in the House of Commons yesterday evening, by the Under Secretary of State for India, that the system had been discontinued. The compulsory examination of women is to be prohibited, and also the making of any regulations which may justly be construed into a legalization of prostitution.

The annual *conversazione* of the Medical Society of London was held on Monday last, and was highly successful. The annual oration was delivered by Sir Joseph Fayrer, who took for his subject the natural history and epidemiology of cholera. He maintained that under certain circumstances English cholera was indistinguishable from its Asiatic congener, and quoted various authorities to show that Asiatic, British, and Damietta cholera differed only in severity and not in kind. He did not believe that the theories of contagion and diffusion by human intercourse explained the movements of cholera epidemics, since neither the frequency, direction, nor rapidity of the spread of the disease bore any relation to the development of means of communication. In many instances the disease had already occurred before the means of contagion had arrived, and in Bengal the course of the disease was upward, that is, not with, but against, the course of the rivers. He believed that hygienic measures afforded the greatest security against cholera, but that cordons and quarantine had utterly failed to prevent its spread. He did not agree with the opinion that it was due to a specific poison.

The "high-altitude" treatment of phthisis has now attained so much popularity, both with the profession and the public, that it is not at all surprising that the whole evening should have been devoted to the discussion of the subject by the Royal Medical and Chirurgical Society at their last meeting. The Fellows of that august body have indeed frequently spent the time of their meetings in discussing at much greater length subjects of far less practical interest. On this occasion the ball was set rolling by the reading of a paper by Dr. Theodore Williams, in which he described the results he had obtained by sending 141 cases of phthisis to various sanitaria at high latitudes. Of this number, forty-one per cent. were cured, twenty-nine per cent. were greatly improved, eleven per cent. were improved, while eleven per cent. of the patients became worse. The improvement was the most marked in the case of patients sent during the first stage. Single-cavity cases gave better results than cavity cases with the opposite lung involved, and left-lung cavities showed less tendency to change, either for better or worse, than cavities in the right lung. To secure the advantages of residence at high altitudes, patients should be free from pyrexia and all acute symptoms, and possess sufficient lung surface to carry on respiration adequately in the rarefied atmosphere. Dr. Williams said the high-altitude treatment was specially adapted in cases where hereditary predisposition to phthisis was present; it was also of value in cases of hemorrhagic phthisis. It was also beneficial in some cases of disease other than phthisis, viz., 1, in cases of imperfect thoracic and pulmonary development; 2, in chronic pneumonia without bronchiectasis; 3, in chronic pleurisy where the lung did not expand after removal of the fluid; 4, in spasmodic asthma without much emphysema; and, 5, in anæmia. He concluded that the treatment was contra-indicated in any of the following conditions: 1, phthisis with double cavities, with or without pyrexia; 2, cases of phthisis where the pulmonary area at low levels hardly sufficed for respiratory purposes; 3, catarrhal phthisis; 4, cases of phthisis with great irritability of the nervous system; 5, emphysema; 6, chronic bronchitis and bronchiectasis; 7, diseases of the heart and large vessels; 8, affections of the brain and spinal cord, and conditions of hypersensibility of the nervous system; and 9, in patients advanced in life or too feeble to take exercise.

In the ensuing discussion Dr. Hermann Weber remarked that he had himself compiled tables of 106 cases which he had sent to high altitudes. His results had not been quite so satisfactory as those attained by Dr. Williams. He did not attach much value to altitude, except as making open air and exercise easy. At Frankenstein, for instance, which was less than 2,000 feet above sea-level, he thought they got quite as good results as in the high Alps. Dr. De Havilland Hall asked whether Dr. Williams agreed with the general opinion that no benefit was to be obtained for cases of laryngeal phthisis from high altitudes except in the cases in which the laryngeal mischief was merely catarrhal? Dr. J. E. Pollock said that altitude was only one of the many agents which might tend to cure phthisis, and on what all the others were we had still a great deal to learn. The cases Dr. Williams had selected to send to the Alps were just the cases that would do well in London also. They had often heard of a rich man's gout and a poor man's. The disease Dr. Williams had been talking about was emphatically a rich man's phthisis. What these people were suffering from who would indulge themselves in their weighing machines and their toboggans, and support their doctors and their parsons, was a very different thing from the malady of *les misérables* with which we all had so much to do nearer home. Dr. Tucker Wise remarked that in the Alps appetites improved and spirits rose in all who could enjoy the sun and take wholesome exercise, and there was little annoyance from lesser colds and coughs. The cold aseptic air acted as a sedative to the cough, and the rooms were often not heated above 50° F. The action of the sun's rays helped to change the white corpuscles of the blood into red, and to develop hæmoglobin. He had noticed that those who perspired readily did not have the usual dyspnœa of a high altitude. Dr. Ewart remarked that rich patients with phthisis suffered here from luxurious living; in the Alps they got physical and mental rest, a complete change, and a fresh spring of hope. He had himself been greatly improved by four winter visits to the Alps, and had been much struck by the comparative want of freshness and vigor in the Riviera. Dr. Huggard had not met with a condition of hypertrophy of healthy lung-tissue in the Alps, such as Dr. Williams had described; the chief change in the chest was increased capacity for movement. Dr. Quain then joined in the discussion and did not seem very amiable. He told Dr. Williams that his statistics were utterly valueless to him; his patients appeared to have got well because they could not help it, and would have got well anywhere. One point went strongly against his sending anyone to the Alps, and that was the unfriendly fashion in which Switzerland had forbidden English physicians to practise there. Dr. Theodore Williams then replied. He was glad, he said, that Dr. Weber, on the whole, confirmed his statistics. He should like to hear more about Frankenstein. He had found, as Dr. Hall expected, that laryngeal phthisis was not benefited at all by high altitudes. He had concluded that hypertrophy of healthy lung-tissue occurred, as there was no other hypothesis to explain the physical facts of increased nausea, chest capacity, and breathing, as shown by the spirometer.

At the last meeting of the Ophthalmological Society Mr. McHardy drew fresh attention to a useful device in the case of patients wearing an artificial eye. This consisted in allowing the patient to wear spectacles glazed with odd lenses, that in front of the artificial eye having a refractive power greater by three dioptrics than that in front of the natural eye. This produced an optical delusion to an on-looker as to the size and level of the artificial eye.

Whatever it may have been formerly, when very different views were held both by the profession and the public as to the action and value of alcohol, there can be no doubt that the opinion of the profession as a body is at the present day strongly in favor of the strictest temperance (by which I do not mean total abstinence) in the use of alcohol, both in health and disease. This is evidenced anew by a fresh medical declaration on the subject of alcohol and its prescription, which is being extensively circulated for signature. Similar documents were prepared and signed by many leading members of the profession in 1839, 1847, and 1871 respectively. In them, as in the present one, attention was drawn to the fact that alcohol is not a necessary article of diet for the healthy, that its value had been much exaggerated, and that it should be prescribed with great care whenever it was thought desirable to administer it.

NYCTALOPIA.—A correspondent of *The Lancet* directs attention to some remarks published by the *Cologne Gazette* on the confusion, in some night manœuvres in Russia, resulting from a large number of the troops being affected with *Hühnerblindheit*, or night-blindness. The affection is well known to result from imperfect nutrition. The following account, given by Dr. Meissner, sufficiently demonstrates the nature of the affection: In a small town of Podolia more than one hundred cases of the complaint occurred. It was the time of the Greek fast, when the inhabitants eat no animal food, but live chiefly on bread and groats prepared with oil. When Easter came they ate the liver of a blackcock or black swine, and were cured in a few days. Meissner examined, both by day and night, many of those affected, but perceived nothing particular in their eyes, except great immobility of the pupils. They maintained they were in perfect health, and would recover their vision in a fortnight. Two of those he examined began to eat liver and animal food, and saw as well as ever on the third day. By the following Sunday all those affected were completely cured. The affection occurs sometimes in nursing women, who are ill-fed, among the poor.

Navy News.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 2, 1888.

CRAIG, F. C., Passed Assistant Surgeon. Detached from Naval Hospital at Norfolk, and to the Naval Hospital at New York.

WENTWORTH, A. R., Assistant Surgeon. Detached from the U. S. S. Galena, and to the Naval Hospital at Norfolk.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 2, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	9	7
Scarlet fever	192	31
Cerebro-spinal meningitis	4	2
Measles	237	17
Diphtheria	176	51
Small-pox	9	3
Yellow fever	0	0
Cholera	0	0

THE LATE DRS. AGNEW AND LORING.—A special meeting of the New York Ophthalmological Society was called immediately after the death of Dr. Agnew, and another after the death of Dr. Loring, and the reports of the committees then appointed were read and accepted at the last regular meeting of the Society.

DR. CORNELIUS REA AGNEW.—The New York Ophthalmological Society records with profound sorrow the death of one of its founders and original members, Dr. Cornelius Rea Agnew, who died of peritonitis on April 18, 1888, aged fifty-seven years, seven months, and twenty days.

Dr. Agnew was President of this Society during the years 1864 and 1865, and was for many years a constant attendant at its meetings. He took a leading part in its scientific discussions, and his opinions, delivered in well-chosen words, were always listened to with that respect to which his vast clinical experience and his sound judgment entitled them.

For over twenty years Dr. Agnew ranked with the foremost ophthalmologists and otologists of the world, and his original contributions to practical, and especially to operative, ophthalmic and otic science, though not comparatively numerous, were exceedingly valuable.

The method devised by him for the removal of secondary cataract has long been referred to and described in all the text-books upon diseases of the eye, and is still accepted as the best method of operating in properly selected cases.

His methods of removing foreign bodies from the cornea, when they are embedded so deeply as to project into the anterior chamber, which was published, with a woodcut, in THE MEDICAL RECORD, Vol. I., No. 11, 1866, is still resorted to as the only available operation in such cases. Later, in 1874, he also published a method of removing a foreign body, deeply embedded in the cornea, by trephining.

The operation for the removal of chalazion, described in "Wells' Treatise on Diseases of the Eye" (4th. Am. Ed., Phila., 1883, page 90), by making an incision through the margin of the lid into the tumor, and then scooping out the contents, was devised by him, though he never published it.

In the *American Practitioner* for January, 1871, he published a paper on the "Treatment of Lachrymal Diseases." In this paper were outlined the methods of treatment which have since been pursued by many ophthalmic surgeons.

In 1875 he published a paper on "Canthoplasty as a Remedy in Certain Diseases of the Eye," in which he made the different steps of the operation clear by means of woodcuts, and in which he modified the operation by recommending a division of the external canthal ligament.

His "Method of Operating for Divergent Squint," by advancement of the internal rectus and tenotomy of the externus, described by him at the meeting of the American Ophthalmogical Society held at the Massachusetts Charitable Eye and Ear Infirmary in 1866, and published in the "Transactions" for that year, has since been practised by ophthalmic surgeons everywhere. He also published a "Contribution to the Subject of Strabismus" in the "Transactions of the American Ophthalmological Society" for 1870.

His last, and perhaps most valuable, contribution to operative surgery of the eye was his "Operation with a Double Needle, or Bident, for the Removal of a Crystalline Lens dislocated into the Vitreous Chamber," published in the "Transactions" for 1885. Other papers published by Dr. Agnew were, "A Method of Dressing Eyes after Cataract Extraction" (1869); a "Contribution to the Statistics of Cataract Extraction of One Hundred and Eighteen Cases" (1874); a "Case of Double, Extremely Minute, and Apparently Congenital Lachrymal Fistula" (1874); "Consecutive Enucleation of Both Eyes for Recurring Glioma" (1875); "Cases of Ophthalmic Diseases in which Enforced Exposure of the Eyes to Light and Air was Salutary" (1876); "A Preliminary Analysis of Ten Hundred and Sixty Cases of Asthenopia" (1876); "Cases of Persistent Pupillary Membrane," (1880); "The Insufficiency of the Ophthalmoscope as the Sole Test of Errors of Refraction" (1880); "Near-sightedness in the Public Schools," THE MEDICAL RECORD, Vol. XII., No. 3.; and, besides these, numerous clinical lectures and cases, and papers on subjects not medical.

Dr. Agnew was taken away when in the meridian of his usefulness. At the time of his death he was a Director of the Manhattan Eye and Ear Hospital, of the Brooklyn Eye and Ear Hospital, a Trustee of the New York Academy of Medicine, of Columbia College, of the College of Physicians and Surgeons, a Governor of the Woman's Hospital in the State of New York, a Manager of the Hudson River State Hospital for the Insane, and of the New York Skin and Cancer Hospital.

His hand was in many great and noble works of charity, and his sympathies were extended to everything that elevates and ennobles humanity. Those who knew him most intimately considered him the highest type of a true Christian gentleman, and felt the absolute integrity of the man in everything that he did.

His loss will be incalculably felt in this city, and in this Society.

HENRY D. NOYES.

DR. EDWARD GREELY LORING.—Dr. Loring joined the New York Ophthalmological Society, January 13, 1868. He was elected the President of the Society, January 12, 1874. He died suddenly in this city, April 23, 1888. During the twenty years in which he was a member of this Society, he was a constant attendant at its meetings; no one was more beloved than he for his many social qualities, and in the scientific work of the Society his word was listened to with a respect accorded to but few. It is fitting that a brief sketch of his life should be entered upon our minutes.

Dr. Loring was born in Boston, September 28, 1837; he was a son of Judge Edward Greely Loring. For a short time a member of the class of 1861 at Harvard College, he went abroad and began the study of medicine in Italy. For three years he was enrolled as a student at Florence and Pisa, and at the university of the latter place he was a devoted student in anatomy of Professor Duranti. In 1862 he returned to America, and in 1864 graduated at the Harvard Medical School, winning the Boylston Prize Essay.

Upon receiving his degree in medicine, Dr. Loring devoted himself to the study of ophthalmology under the direction of Dr. Hasket Derby, of Boston. He was appointed ophthalmic externe by Dr. H. W. Williams, at the City Hospital, and subsequently served for a short term at the Massachusetts Charitable Eye and Ear Infirmary.

In 1865 he established himself in practice in Baltimore, remaining there but little over a year, when he came to New York, to become associated with the late Dr. C. R. Agnew. Four years later this partnership was dissolved, and until his death Dr. Loring has practised medicine in New York City.

He was a surgeon of the Manhattan and Brooklyn Eye and Ear Hospitals, and subsequently a consulting surgeon of the latter institution. He was in 1874 appointed an ophthalmic surgeon of the New York Eye and Ear Infirmary, and held a similar position at St. Luke's Hospital.

Original in thought, scientific in method, bold in execution, Dr. Loring was a skilful surgeon, a thoroughly trained physician. As an author he was conspicuously known, both in this country and abroad, for his original contributions to medical literature. In this brief memoir it would not be in place to discuss the value and extent of his literary work. His writings were upon nearly every subject embraced in the science of ophthalmology. His text-book of ophthalmoscopy, the completion of the second volume of which occupied the last days of his life, will remain for all time his most lasting memorial.

Dr. Loring made the refraction ophthalmoscope a working instrument, to which nothing of any importance, except the tilting mirror, has been added since. By whatever name the latest manufacture is known, this instrument is still the Loring ophthalmoscope—vastly better than all its predecessors.

In the discussions of this Society he was frank and straightforward in his action and speech, scholarly in his address—the type of a brilliant, honest, and independent man. A keen observer, unfettered by the traditions of the schools, his opinions based on sound anatomical and physiological knowledge, he was a hater of sham, a follower of truth for the truth's sake.

CUNDURANGO IN CANCER OF THE STOMACH.—In the *New Yorker Medizinische Presse* for April, Dr. Franz Foerster reports four cases presenting all the symptoms of cancer of the stomach which were treated with this drug. In two cases no favorable effect was noticed; in the third he believes that life was prolonged, while in the fourth case a positive and permanent cure resulted. The dose is half a drachm of the fluid extract.

THE USELESSNESS OF ERGOT IN SUBINVOLUTION.—Some very interesting observations were recently made by Dr. Emile Blanc on the effect of ergot in involution of the uterus after labor. A fairly large number of women who had gone through normal labor were divided into three categories. Forty of them were left to Nature; forty were treated with daily hypodermic injections of Yvon's solution of ergotine (1 c.c. = 1 gramme of ergot) during the first five days after delivery; and the remaining twelve were similarly treated for ten days. Daily external measurements were then made in all the cases to ascertain the size of the uterus, and on the fifth and tenth days its internal measurement was taken by means of the uterine sound. It was found that the administration of ergot during the first five or ten days failed to produce any favorable effect in hastening the process of involution, but that, on the contrary, it seemed to delay the normal retraction of the uterus. Ergot is nevertheless an exceedingly useful agent in the treatment of secondary hemorrhage, and its action is more marked the less the interval of time that has elapsed since the confinement.

THE SEVENTH GERMAN CONGRESS FOR INTERNAL MEDICINE was held in Wiesbaden, on April 9–12, 1888. At the opening session the President, Professor Leube, delivered the annual address, in which, after referring to the death of the emperor, he dwelt especially on the present condition of medical science and the part Germany was taking in the rapid progress now being made in all branches, but especially in bacteriology. The first subject for discussion was the "Treatment of Chronic Diseases of the Myocardium." Professor Oertel spoke at length of the method, called by his name, of exercise for strengthening the heart muscle. After referring to the quantitative and qualitative changes occurring in the cardiac muscle, he reviewed the modes of treatment in vogue in the past. These were essentially absolute rest and a starvation diet. His method was exactly the reverse of this, namely, a nourishing diet composed largely of meat, and exercise for the heart. In addition to this it was necessary to lessen the amount of labor which the heart was called upon to perform by reducing the quantity of water in the body. This end was best accomplished by gymnastic exercises and especially by mountain climbing, which afforded the needed exercise to the heart and also promoted excretion of the watery elements by means of the increased perspiration. The ingestion of fluids should also be restricted as far as possible. The chief contra-indications were disease of the kidneys and severe chronic pericarditis. Professor Lichtheim opposed Oertel's method in almost every particular, believing it to be often exceedingly dangerous in practice, as well as erroneous in principle. He spoke at some length of the purely medicinal treatment of these affections. Other speakers also opposed the mechanical therapy of disease of the cardiac muscle. Professor Rumpf reported five cases of "Wandering Kidney." Professor Unverricht read a paper on the "Mechanism of Respiration," and detailed certain experiments which showed that irritation of certain points in the upper portion of the cerebrum had a marked influence on respiration. The question of "Alcohol as a Remedy" was discussed at some length by Professors Binz, von Jaksch, Nothnagel, Erb, Merkel, and Rühle. The general opinion was that the free use of alcoholic beverages was an evil, and that, while the drug is frequently a most valuable and indispensable remedy, it is often prescribed too indiscriminately, and may in such cases be productive of positive harm. Professor Adamkiewicz read a paper on "Degeneration of the Spinal Cord." Professor Leyden presented a communication on the "Treatment of Stricture of the Œsophagus" by a new method. These strictures are mostly cancerous in nature, and the only treatment admissible is palliative, the aim being to open the stricture sufficiently to permit of the administration of nourishment. English physicians had succeeded, in some cases, in opening the stricture and keeping it patent by means of a short cannula. The speaker had tried this method in certain instances with happy effect. He attached threads to the tube, so that it could be removed if necessary. No solids should be taken, for fear of clogging the cannula, but fluid nourishment could be taken in sufficient quantity to sustain life. One patient, whom he had treated in this way, had worn the tube for ten months, and gained considerably in weight. Professor Rühle had not employed the cannula, as at times some force was required in its introduction, and he had feared a rupture of the œsophagus in case the stricture was caused by the pressure of a soft carcinoma. A discussion on the "Treatment of Asiatic Cholera" was participated in by Professors Pfeiffer, Cantani, Berger, Stann, and others. The first speaker was a firm believer in the contagion theory, and opposed strongly Pettenkoffer's views of the origin of cholera. The annual dinner was largely attended, and, notwithstanding the recent discussion on alcohol, many toasts were drunk, and were felicitously responded to by many of the distinguished guests. About three hundred members were present at the Congress. It was decided to hold the next meeting at Wiesbaden, as in former years, although many of the members favored Berlin.

ALARMING EFFECTS FOLLOWING THE RAPID EMPTYING OF A DISTENDED BLADDER.—A correspondent writes as follows to *The Lancet:* "F. H——, aged twenty-three years, well built, perfectly healthy, left Lime Street, Liverpool, by the 12.45 night train for Edinburgh. An hour before starting he had eaten a hearty supper, with which he drank a pint of beer. During the journey he lay down reading and smoking, and fell fast asleep half an hour before reaching Carlisle. When the train stopped at Carlisle (at 4.15 A.M.), he awoke suddenly and hurried to the urinal, which happened to be exactly opposite the compartment in which he was travelling. After micturating freely, he in a few seconds felt slightly sick, and then, becoming 'quite blind' and insensible, fell backward full length. He was set on his feet by his fellow-passengers, and, though slightly dazed, feeling as if his head were 'ice cold,' and staggering, he walked back to the train. Ten minutes later he could scarcely realize that anything extraordinary had happened. With the exception of soreness about his elbows, head, and buttocks, which (owing to the heaviness of his fall) lasted two or three days, he experienced no further inconvenience. As he had never fainted or had a fit of any kind in his life before, my friend was naturally somewhat puzzled, if not alarmed. There can be no doubt that this was a case of fainting due to rapid emptying of a somewhat distended bladder. (He had not passed urine for four hours.) Dr. Lauder Brunton gives a very lucid explanation of this accident (if it may be so called) in his work on therapeutics. The case very well illustrates the points on which Dr. Brunton lays stress—viz., sudden awaking and rapid emptying of the distended bladder."

DECREASE IN RURAL MORTALITY.—A Presbyterian clergyman who has served in the ministry for nearly fifty years furnishes some interesting statistics and observations relating to the increasing longevity in the rural districts of Central New York. He has attended five hundred and seventy-three funerals altogether since 1840. The average length of life of the first hundred dead whose funerals were attended was twenty-six and one-half years, seven of these having lived over seventy years; of the second hundred the average was thirty-six years, and thirteen over seventy years; of the third hundred, the average was thirty-seven, and twenty were over seventy years old; of the fourth hundred the average was thirty-seven, and twenty-eight were over seventy; of the fifth hundred the average was thirty-seven and one-half, and thirty-two were over seventy; and of the remaining seventy-three the average was fifty-eight, and thirty-two were over seventy, the oldest of the seventy-three being the late Levi Hanford, of Walton, who died at ninety-six. These remarkable figures, it should be noted, apply to an interior farming population, from which large numbers of the young folks "go West" or to the big towns, and where the quiet and wholesome environment of rural existence promotes longevity to an unusual degree. The venerable clergyman's records also show that of infants now born fewer die in childhood in proportion to births than died in years gone by. Not as many children are now born in proportion to the population as were born twenty-five to fifty years ago. There are more deaths proportionately caused by drunkenness and by lung complaints in these days than in former years, and these fatalities serve to keep down the comparative scale of longevity below what it would otherwise reach. The increasing length of years attained by the rural population is attributed to the exemption of the present generation from the severe toils and hardships encountered by their progenitors in clearing up the wilderness, and to the better understanding and observance of the laws of health.

Some Antiseptic Preparations.—*Antiseptic Silk.*—Buy good sewing (not embroidery) silk of various thicknessess; remove the labels from the ends of the spools; boil for two hours (without removing from the spools) in ten per cent carbolic or plain water; store in alcohol in wide-mouthed bottle. Before operation soak corked bottle in sublimate solution. During operation remove cork, draw end of thread over edge of bottle and cut off ligatures or sutures as required. In the abdominal cavity use nothing but silk.

Antiseptic Sponges.—Buy in bales, at a cost of about two cents each. Beat out calcareous matter, soak in ten per cent hydrochloric acid solution for twenty-four hours, wash thoroughly in soft soap, put in five per cent. carbolic for three days. Dry in sun, in clean place; place in muslin bags and hang up in dry, clean place, or store in preserving jars, in three per cent. carbolic. Extreme care should be used in the management of the sponges during the operation. Those which have come in contact with pus, feces, etc., should be thrown under the table. Those which are only bloody may be rapidly washed in hot boiled water, and handed to the operator as he needs them.

Corrosive Sublimate Solution.—To make this salt soluble in water, it has been used in alcoholic solution, or double the quantity of common salt or chloride of ammonium has been added. The best formula is as follows:

Corrosive sublimate,
Hydrochloric acid.................. āā 1 drachm.
Distilled water, enough to make........ 1 ounce.

This forms a perfect and permanent solution. One teaspoonful to a pint of water makes a solution of 1 to 1,000. Or the solution may be made with tartaric acid.

Boro-salicylic Solution (Thiersch's).—This, which is called Thiersch's solution, and which is much used in Germany in peritoneal operations, on account of its blandness, is made by adding two parts of salicylic and twelve parts of boracic acid to 1,000 parts boiled distilled water. —Haynes, *Southern California Practitioner.*

How to Remove the Wounded.—Assistant Surgeon James E. Pilcher, United States Army, read a paper on March 21st, before the Military Service Institute at Governor's Island, on the "Transportation of the Wounded. Dr. Pilcher confined himself to that part of the subject connected with the removal of wounded men from the field by human bearers, and illustrated the methods he favors by having them rehearsed before the audience by a squad of men whom he had trained. He advocated the carrying of stretchers in the hands of bearers instead of on their shoulders, as was common in the civil war. He reminded his hearers that Stonewall Jackson was killed by the falling of one of the litter-bearers who were carrying him with the litter-handles resting on their shoulders.

Regulation of Vice.—The long debate at the Academy of Medicine on the public prophylaxis of syphilis, or, rather, the police regulation of prostitution, has been brought to a close, but the question remains exactly where it was when the discussion began. No less than thirty-three articles have been proposed by the Commission through Dr. Fournier, its reporter, on the best measures that should be taken to prevent the spread of the disease. Scarcely any of the articles have been accepted as proposed, as each speaker who took part in the debate had something to take from or to add to them. Dr. Diday, of Lyons, made a most interesting communication on the subject of prostitution. Formerly, he said, there were two sorts of prostitution—viz., that of licensed public houses (*maisons de tolérance*) or closed prostitution, and street or open prostitution. The progress of civilization has given birth to a third form, *la prostitution entr'ouverte*, or what may be termed clandestine or unlicensed prostitution, which is practised particularly in drinking shops where women are employed. To remedy this state of things, Dr. Diday proposed that Paris and other large cities should follow the example of the city of Lyons, where young women who are so employed should furnish every three months a certificate of good conduct and of good health under a penalty of a fine for any omission of the same, for which the masters are responsible. This declaration simply excited a smile, and one of the members facetiously remarked that if Paris should wish to preserve its title of the first city of France, it had only to exact from all the young women of wine or beer shops certificates similar to those exacted from the *employées* of Lyons as a proof of their morality. In the course of the debate, Dr. Le Fort made frequent allusions to the salutary effects of the English law respecting prostitution, but Dr. Brouardel took another view, and drew a comparison strongly in favor of the Paris system.—*Lancet.*

The Village Doctor.—Mr. Julian Hawthorne, in the *American Magazine*, gives this true and graphic picture of the country doctor: "One of the most entertaining people in the village is the doctor, for, however closely he may be allied with his patient-community, he must also be, to a greater or less extent, a man of the world. The time you spend with him will surely not be thrown away—unless, indeed, you visit him in his professional capacity; then it will all depend on circumstances. A doctor, in America, is very apt to have been a traveller; and, being an American, to have seen a great deal that the ordinary traveller misses. His knowledge of the inside of his fellow-creatures seems to assist him in observing facts connected with their external environment; he is comparatively free from prejudices, and his opinions upon things in general are dictated by solid common-sense. His professional training tends to sharpen his insight into human nature, and, if his own nature be sociable and humane, he forms many agreeable acquaintances in all parts of the world. In the seclusion of his rural study, shadowed by the elm-tree on the lawn, and rendered fragrant by the lilac-bush under the window, he cons over the latest discoveries of science, and meditates wisely and discriminatingly upon politics, literature, and art. He is amiably sceptical, and he is cheerful by force of professional habit; you may interest and amuse him, but you can scarcely surprise him; and he will easily detect in you, and demurely satirize, any tendency to indulge in the Munchausen vein. He is not a wealthy man, and most of his fees are paid in commodities other than coin, when they are paid at all; yet he has enjoyed his life, and has the consciousness of having been of some benefit to his fellow-creatures, if only by removing them to a happier sphere. But if he be the best man in the village, the reason is, it must be confessed, because he belongs to it only in the physical sense; his mind and faculties and his higher sympathies have a far wider range. He resides there because he was born there, and because a man who has surveyed existence in its larger aspect cannot do better than spend his closing years where his years began."

Early Remembrances.—Dugald Stewart was once asked what was the earliest thing he could remember. He said it was being left alone by his nurse in the cradle, and resolving to tell of her as soon as he could speak. This record, however, does not equal that of the American who remembered that, in his early embryo-life, he had a fear that, perhaps, he might be born a girl.

The Medical Record

UNUSUAL CASES OF PELVIC CELLULITIS AND THEIR TREATMENT.[1]

By JAMES B. HUNTER, M.D.,

NEW YORK.

On looking over a large number of cases of pelvic inflammation in search of those which could appropriately be termed "unusual," I have been struck by the great variety which they present, and have found a difficulty in selecting cases that were not unusual. Few if any other diseased conditions are liable to so many varieties in degree and in kind. All I shall attempt at this time will be to give the outlines of a few cases occurring in my own practice, with the means of treatment adopted in each, in the hope that I may provoke discussion on a subject of very general interest.

Case I.—This patient was a married woman, thirty years of age, who had had two children, and, three months before entering the Woman's Hospital, a miscarriage, probably induced. She was suffering severe pain, and had a temperature constantly high, varying from 100° to 104° F., with weak and rapid pulse. There was much vomiting, and scarcely any food could be retained. Examination showed a large mass on the left side of the pelvis, pressing the uterus over to the opposite side. The uterus was fixed. There was an indistinct feeling of fluctuation in one part of the tumor, the upper margin of which could be felt behind the pubes. After consultation with my colleagues, laparotomy was decided upon as the safest method of evacuating the contents of the abscess. On making a small incision the mass could be distinctly felt behind the uterus; while firmly attached to the margin of the tumor was a coil of intestine, which would inevitably have been wounded had an attempt been made to evacuate the abscess by vaginal puncture. It was found impossible, without incurring great danger, to make an incision into, or even to aspirate the mass, surrounded as it was by adherent intestine. The wound was therefore closed. The patient had apparently reached a crisis, and from that time improved slowly, and after a few weeks left the hospital. I saw and examined her one year afterward, when she was in excellent health, and could find scarcely a trace of the abscess, the uterus being movable and in position.

This case illustrates not only the great danger that may attend surgical operation, and also the fact that very bad cases sometimes recover without interference. The condition of the patient when at her worst would have justified the resort to almost any procedure, however dangerous, that would give any hope of relief or cure.

Case II.—This was the case of a private patient, aged twenty-eight, who when two months pregnant had an abortion produced, in consequence of constant and intolerable pain and vomiting. The contents of the uterus were evacuated under ether, with the utmost antiseptic precautions, and the patient did perfectly well until the tenth day, when she was moved from the bed to the sofa. On that day she had a chill, accompanied by severe pelvic pain on the right side, and a sudden rise of temperature. On examination the uterus, which had been in position, was found to be displaced to the left, an indistinct mass being felt upon the right side. No fluctuation could be detected at any point. The temperature varied for the next five days between 101° and 104° F., and there was intense pain, requiring the frequent use of morphia. On the sixth day a soft fluctuating point was discovered in the mass, and the small needle of the aspirator was introduced, bringing away about an ounce of fetid pus. On withdrawing the needle slowly, some urine followed, clear and unmixed with pus. The pain was relieved, and the temperature was lower during the next four days, at the end of which time there was fluctuation in another part of the mass. A narrow bistoury was introduced at that point, and about half an ounce of very thick, almost cheesy, pus escaped on pressure. The condition of the patient continued to be unsatisfactory, pain coming on suddenly at times, and the temperature varying between 99° and 104° F. with a weak and rapid pulse. I then determined to open more freely with the knife, and, in order to ascertain the situation of the pus, I passed a small trocar, as a preliminary measure, at a point behind and to the right of the cervix, trying to avoid the bladder. Pus escaped freely, but, on withdrawing the trocar in order to enlarge the opening, a very profuse hemorrhage occurred. The trocar had evidently cut through the displaced uterine artery. I rapidly enlarged the opening, and was able, with much difficulty, to grasp both ends of the artery with long pressure-forceps. During this procedure I introduced the finger and broke up some partitions separating the collections of pus, but I do not believe that it was all evacuated, or that all the pockets were reached. The forceps were left *in situ* for thirty-six hours, a firm tampon being introduced. All hemorrhage was checked in this way; but for two days afterward a large quantity of blood and pus appeared in the urine. All the bad symptoms subsided rapidly, and the patient made a good convalescence. The temperature became normal and remained so, and there was no considerable pain after the operation.

I have no doubt that the bladder was injured twice in this case, but no evil result followed. There must have been extraordinary displacement of that organ, as I chose a point as far back as possible in order to avoid it, warned by the first accident. I was also on my guard against wounding the artery, and endeavored carefully to find a point at which no pulsation could be felt.

Case III.—This case came into my service in the Woman's Hospital, suffering from well-marked pelvic cellulitis. The patient was thirty-four years of age, married, and had had children. The cause of the inflammation was obscure, as no satisfactory history could be obtained. There was a large mass on the right side of the uterus, apparently connecting with a smaller mass on the left side. On examination under ether it was thought that deep fluctuation could be obtained, but puncture with a large trocar at the softest point, and the use of the exploring needle at three other points, failed to bring pus. The condition of the patient was bad, and growing rapidly worse. An incision was therefore made in the right groin, and an attempt made to reach the contents of the mass without entering the peritoneal cavity, but without success. The weather was very warm, the hospital was about to close, and the friends of the patient were very anxious to take her away to the country, as they supposed, to die. Four months later I learned that her condition had very much improved during the summer, but that, so far as she and her friends were aware, there had been no escape of pus by the vagina or rectum, and no sudden relief. I saw and examined her some months later, and found her in a condition of satisfactory convalescence. The uterus was still fixed, but some induration around it was all that remained of the pelvic abscess.

---

[1] Read before the Obstetrical Section, New York Academy of Medicine, April 26, 1888.

Case IV.—This patient was a woman, forty years of age, who when I first saw her had been confined to her bed for several weeks, and gave a history of having had much fever, great pain in the abdomen, and nausea. On examination the pelvis was found apparently filled with a solid mass, in which the uterus could not be distinguished. As fluctuation was discovered at one point, an exploratory puncture was recommended, and preparations were made for that operation; but a sudden escape of offensive pus from the cervix, as distinctly seen through the speculum, gave great relief, and rendered operation unnecessary. For several months afterward there was apparently a re-accumulation of pus, accompanied by pain and a high temperature, and in place of menstruation the same profuse discharge, and consequent relief.

Case V.—This patient was seen in private practice, in consultation. She had been seen by several physicians, who agreed in the diagnosis of pelvic abscess and salpingitis. The mass was not punctured, but, after many weeks of suffering, laparotomy was performed, and there was found not only extensive diffuse, pelvic peritonitis, with a number of small abscesses, but also salpingitis, the tube on one side being distended with pus, and also a dermoid cyst, the whole being bound firmly together by adhesions. The case terminated fatally. The lesson to be drawn from it was the danger in such a case of puncture, aspiration, or even the use of the hypodermic needle. If the needle had not reached the cyst it would have given no information as to the character of the tumor, and if it had reached it, the cyst being very tense, either collapse or fatal peritonitis would almost certainly have followed. The case is instructive also as showing the difficulty of making a diagnosis in cases of extensive pelvic inflammation. Several gentlemen of large experience in gynecology and obstetrics, expert diagnosticians, had examined the case carefully without so much as suspecting the existence of a dermoid cyst about or nearly four inches in diameter.

Case VI.—This case was that of a patient thirty years of age, never pregnant, who had been subjected to severe treatment by forcible dilatation of the uterine canal, on account of sterility. Extensive pelvic inflammation followed, and when first seen by myself her condition was not unlike that of the case last reported. The question of puncture had been seriously considered, but there was no point of fluctuation; and there was evidently salpingitis, with a discharge of pus from the uterine canal immediately after each menstrual period. After much suffering and prolonged treatment at the hands of several specialists, laparotomy was resorted to as affording the only hope of relief. A large, thin-walled sac of fetid pus—the distended tube—was found on the right side, and in manipulation was unavoidably ruptured. Though the abdominal cavity was thoroughly cleansed, a fatal peritonitis resulted. The case is mentioned simply to illustrate the possible danger, and the certain inutility, of puncture or other vaginal operation in similar cases.

Case VII.—This patient was twenty-one years of age, and pelvic inflammation developed ten days after a normal confinement—the first. The disease was signalized by a sudden rise of temperature, accompanied by pain and tenderness on the left side of the uterus, and the development of a mass quite distinctly felt on bimanual examination. This tumor persisted for several weeks, growing gradually smaller, and giving rise to less marked symptoms accordingly. Everything pointed to a circumscribed pelvic abscess, and the probable necessity for interference was constantly borne in mind. There were, however, domestic and other reasons—the case occurring in midsummer—for postponing to the last moment compatible with safety any surgical procedure. Without interference the patient gradually made a complete recovery.

Diagnosis.—The cases thus briefly outlined serve to illustrate the great difficulty and uncertainty of diagnosis in recent pelvic inflammation. The difficulty would be less if all the cases could be observed from the outset; but we are commonly called to see them when the disease is well advanced, and at a period of all others the most unfavorable for diagnosis. The cases are also obscured by complications. Pelvic abscess and salpingitis commonly go together.

The following conditions may simulate or complicate pelvic cellulitis: Salpingitis with dilated tube; dermoid cyst; suppurating or other ovarian cyst; cyst of broad ligament; hæmatocele; soft uterine fibroid; retroflexion or retroversion with adhesions; latero-flexion or version, with or without adhesions; encysted pus resulting from peritonitis; solid or semi-solid ovarian tumor; extra-uterine pregnancy; normal pregnancy.

These are some of the conditions and complications which may serve to make us modest and doubtful in our diagnosis, and the possibility of their existence should never be lost sight of.

Treatment.—As the diagnosis of pelvic inflammation is subject to much uncertainty, the treatment must be adapted carefully to each individual case. The good surgical maxim, that pus wherever it exists should be evacuated, does not apply invariably to cases of pelvic abscess. There are cases where the danger of resorting to surgery is greater than the danger of waiting. No inflexible rule can be laid down for our guidance in such emergencies. There is, perhaps, no class of cases in the whole domain of surgery in which good judgment is more imperatively necessary than in the class under consideration. And there is always an element of uncertainty even in the most favorable and apparently the simplest cases. The anatomical relations of the parts are so distorted, and the conditions of the organs so much changed, that we must always be prepared for the unexpected. All such cases, if seen early enough, should be carefully examined at least once in twenty-four hours, as they often undergo rather sudden changes. The temperature and pulse should be noted at least three times in the twenty-four hours, and the general condition of the patient should be carefully scrutinized. Constipation should be guarded against, as it is a very serious embarrassment in examining the patient. When there is so much pain or tenderness as to prevent a satisfactory examination, a little ether or chloroform should be given whenever there is a doubt as to the actual condition. When any one part of the mass which presents in the vagina begins to soften, the question of evacuation should be seriously considered. The following methods may be employed: The hypodermic needle, the aspirator, the trocar and cannula, the knife or scissors, Paquelin's cautery, the exploring needle.

Of these methods the hypodermic needle is utterly useless; and aspiration with a small needle, though some pus may be withdrawn, is of little practical utility. If evacuation is decided upon, the best way to do it is unquestionably by means of the knife—a narrow-bladed, curved bistoury answers very well. The ordinary exploring needle should be used first, and followed by the free use of the knife, in a region as remote as possible from large veins or arteries. The cautery has no advantages over the knife, and is much less manageable. The pus is often so thick that it will not flow through even a large cannula, and small needles are therefore not only useless, but misleading, as they may fail to show the presence of pus.

The operation should be undertaken with a full appreciation of its dangers and its uncertainties: arteries or veins of large size may be injured; the bladder or ureters may be wounded; a dilated tube may be cut into, while the abscess proper may not be reached. But, notwithstanding these dangers, the operation described is often the best and safest resource at our disposal. It is seldom, however, that a single puncture will evacuate more than one small collection of pus. It is well, therefore, to make the incision large enough to introduce the finger, which is safer here than any other instrument, to break down the partitions between the various pockets of pus, and make the evacuation thorough. It will then be necessary to drain the cavity. A piece of soft rubber drainage-tube may be fastened in the wound by a suture of silk or silver wire, and the cavity thus frequently irrigated with an antiseptic solution. Or the cavity may be packed with iodoform gauze, which must be frequently changed.

The operation should never be undertaken without ample assistance, and an abundant supply of instruments to meet any emergency. The patient should be etherized and placed on the side on a table, and Sims' speculum employed, in the hands of a skilful nurse or assistant. There is no excuse for surprises, for the operator should be prepared for anything that can possibly arise. Among the instruments which should be in readiness are: Sims' speculum, artery- and pressure-forceps of various sizes, knives and scissors, a director, needles straight and curved, needle-holders; ligatures of silk, catgut and silver wires; dressing-forceps, Paquelin's cautery; plain cotton and alum cotton, absorbent and non-absorbent, in large quantity, prepared for tampons; dressing-forceps, etc., and a lamp or reflector to insure good light in case an operation is done at night. An abundant supply of hot water should be at hand, and several pus basins or small vessels for use in irrigation. Ether and chloroform should always be in readiness.

Conclusions.—My experience and observation warrant me in arriving at the following conclusions:

1. That while a certain number of even bad cases of pelvic abscess recover without treatment, and do not rupture spontaneously, there is, nevertheless, a large element of danger in the expectant treatment—as of rupture into the rectum or into the peritoneal cavity, or of septic poisoning or septic peritonitis.

2. That no inflexible rule can be laid down as to surgical treatment, which must always be contingent on the severity of the symptoms, the progress of the disease, and the general condition of the patient.

3. That vaginal incision, thorough evacuation, and free drainage constitute by far the best and safest method of treatment in a large number of cases.

4. That the dangers of surgical interference are unquestionably considerable, even under what seem to be favorable circumstances, but that they are reduced to a minimum if the operator is fully prepared for any emergency, and is vigilant and uncompromising in the employment of antiseptics at every stage of the treatment.

5. That injury to the bladder cannot always be avoided, but is not usually a serious accident.

6. That injury to the large arteries or veins, if proper precautions are taken, need never result in fatal or even serious hemorrhage.

Tubercular Ulceration in the Nose.—Dr. M. A. Veeder, of Lyons, N. Y., writes: "In the second edition of Beverly Robinson's treatise on 'Nasal Catarrh,' it is stated that the author does not remember to have seen a well-defined ulceration of tubercular character in the anterior or posterior nasal passages. A case that recently came under the observation of the writer appeared to be of this variety. The patient was in the last stages of tubercular consumption, a cavity having formed in one lung, and the larynx being the seat of extensive ulceration, causing loss of voice. The nasal septum also was much inflamed and was perforated, the lesion apparently being entirely similar in its origin and progress to the ulceration in the throat."

The Physician's Bedside Record is the title of a very conveniently arranged clinical record, devised by Dr. S. C. Segur, of Hartford. It can be made to serve as a memorandum for the nurse's direction, and also for keeping a history of the case from day to day. It is compactly arranged and of small size, so that it may easily be filed away, and take the place of the large case-book.

THE TREATMENT OF STRICTURE OF THE URETHRA BY ELECTROLYSIS.[1]

By T. H. BURCHARD, M.D.,

LECTURER ON SURGICAL EMERGENCIES, BELLEVUE HOSPITAL MEDICAL COLLEGE; ATTENDING SURGEON, CHARITY AND COLORED HOSPITALS, ETC., NEW YORK.

After an experience of sixteen years, embracing the care of nearly four hundred cases of stricture of the urethra, it seems somewhat surprising that at this late date the author should just have begun to appreciate the merits and foresee the possibilities of a method of treatment which hitherto he has looked upon with suspicion and distrust.

In 1872, while house-surgeon at Bellevue Hospital, I requested our fellow-member, Dr. Robert Newman, to treat according to his recently devised method of electrolysis some few cases of stricture of the urethra.

For causes now forgotten, these cases did not do especially well, and the treatment was abandoned. Since then I have never been sufficiently impressed with the advantages of the method, although they have been most enthusiastically presented by its advocates, until after reading Dr. Newman's more recent contributions, especially his paper read before the New York State Medical Association, November 25, 1885, and his subsequent synopsis of one hundred cases of stricture treated by electrolysis, read before the American Medical Association, June, 1887, to give it the unprejudiced trial that a new method of treatment is entitled to receive.

The following case was selected for experimentation:

J. B——, thirty-two years of age, good general health, and temperate; expressman by occupation. Had gonorrhœa with swelled testicles two years ago; the discharge has continued, off and on, up to the present time. Has been under treatment at several of the city dispensaries and hospitals, and has given the various treatments proposed more than ordinary attention. November 2d: Is now complaining of painful micturition, diminished and divided stream, and gleety discharge.

Meatus admits bougie à boule, No. 14, French. At two and a half inches from meatus, there is a quarter-inch contraction, barely admitting No. 12. At five and one-third inches, a second stricture half an inch long admits with difficulty No. 7.

The membranous urethra unusually granular, bleeding quite profusely on the passage of instruments. Bladder irritable. Urine alkaline; specific gravity, 1.028; containing pus with phosphates.

Meatus incised to No. 32 French.

Newman's insulated olivary bougie, No. 14, passed to first stricture. Current from six cells (Dreicher's forty-cell battery, zinc and carbon elements) passed through bougie, connected by negative pole, for fifteen minutes, when the bougie *slipped* gently through the stricture.

No further attempt at electrolysis was made that day. Not the slightest pain was produced and no unpleasant symptoms followed.

November 11th.—Newman's bulbous bougie, No. 15, was passed and engaged in the stricture; current from eight cells for seven minutes producing no pain, only a slight sense of discomfort, permitted the ready passage of the bougie.

The absolute painlessness of the procedure tempted me into essaying the deep stricture five and one-third inches from meatus. No. 8 bougie, six cells, fourteen minutes, passed readily to the prostate.

November 13th.—Not the slightest unpleasant result followed the passage of the bougie. The stream seems rather reduced in size.

November 17th.—Both strictures submitted to a mild current, six cells, eight minutes each. Bougies Nos. 9 and 11 passed lower stricture; No. 17, superficial stricture.

From this time on, bougies were passed once a week, until December 29th.

---

[1] Read before the Northwestern Medical and Surgical Society, April 18, 1888.

January 3d.—Bougie à boule and Otis' urethrometer fail to detect any appreciable contraction. The discharge has entirely disappeared, the patient passing a full-sized stream.

April 7th.—Steel sound No. 30 passed readily into the bladder, no instrument having been passed for five weeks.

In reviewing the above case, I unhesitatingly express my belief that the treatment was conducted with less pain to the patient and followed by a better result, obtained in a shorter time, than possibly could have been obtained by any other method of treatment with which I am familiar.

Ordinarily, the first stricture I should treat by internal division—reserving electrolysis for the deeper one—and this is my present method of procedure for all anterior strictures, and for those of a not particularly dense composition.

CASE II.—J. S——, aged twenty-eight, German, bootmaker, dissipated. Has had repeated attacks of gonorrhœa and been under the care of many surgeons for stricture and gleet. Has had internal urethrotomy performed twice. The urethrometer shows numerous contractions from the fossa navicularis to a depth of five and three-fourths inches; No. 9 bougie à boule can be passed to a depth of three inches—when it is arrested against a tough, gristly stricture, about half an inch long, which admits No. 6 with difficulty.

November 4th.—No. 5 Newman's insulated bulbous bougie was engaged in the stricture and connected with negative pole. Positive pole placed over Scarpa's space. Current gradually increased until ten cells were in circuit. At the expiration of eight minutes, the bougie slipped through the stricture to encounter another at the depth of five inches. No further attempt was made at this sitting. An insignificant flow of blood followed the withdrawal of the bougie. No pain was experienced. The same evening the patient suffered from retention of urine. A whalebone guide was passed with great difficulty, and on this a No. 3 tunnelled catheter. A pint of water was drawn. No unpleasant result followed. Considerable scalding in micturition was experienced for the three successive days.

November 11th, 18th, 24th, and December 1st.—Bulbous bougies Nos. 8, 10, 14, 18, and 30 were successfully passed.

April 2d.—The patient was examined to-day for the first time in three weeks. A steel sound, No. 30, passed readily into the bladder, a slight obstruction being encountered at the depth of three inches. A slight gleety discharge remains; nothing, however, when compared with what it was in November. At no time during the past seven years has the patient's urethra been in as good a condition, or been as free from pain, or able to pass as large a stream as he has since electrolysis was commenced.

Seventeen other cases, embracing forty-one strictures (not including those in the first two inches), and varying in size from 9 mm. to 22 mm., have been subjected to this method of treatment. In two instances only has the pain been of sufficient severity to necessitate the subsequent use of anodynes. The utmost delicacy in the necessary manipulations has invariably been exercised in order that pain might be eliminated as far as possible. The same precaution has been observed in intensifying the current; commencing the séance at zero, and gradually bringing as many cells into use as the patient's own sensibility made possible. The fewest number of cells required—from a 40-cell Dreicher battery—to produce any appreciable electrolytic effect was five, and the largest fourteen. The longest séance was twenty minutes, in the case of a dense traumatic stricture situated in the membranous portion. The average length of the application has been not far from ten minutes to each stricture.

Regarding the duration of treatment, I have been surprised at the rapidity of cure. In several instances in which gradual dilatation has been employed for months, far better results were attained by electrolysis in weeks. After a stricture of average density has been electrolyzed up to about 20 mm.—from, say, eight or ten—its subsequent disappearance is more rapid than it was at the commencement of treatment.

In several instances I have noticed that at the second or third sitting comparatively little advance was made, whereas at the sixth or seventh a gain of several numbers, as determined by the urethrometer, was made between each séance.

Regarding the interval that should elapse between the sittings, I am convinced that a mistake is made in making them too near together in the earlier stages of treatment.

In five cases in which I purposely examined the urethra with the urethrometer on the second and third days after electrolysis, I found a diminution of the canal, from swelling, varying from 2 to 5 mm., although in each case of the five, at the expiration of a week, and after all swelling had subsided, there was a gain in the urethral calibre of from 3 to 5 mm.

Another observation of importance is the smoothness of the lining membrane of the urethra as compared to its condition after either dilatation or division. The sensation, as conveyed to the finger by the passage of either a steel sound or a bougie, or both, is suggestive of a more normal elasticity and smoothness. This was most strikingly shown in the case of traumatic stricture above referred to—a case that had been condemned to external section, and in which electrolysis was resorted to as a *dernier ressort*. The cure in this case is not complete, but the progress is gratifying, although somewhat tardy. In nine sittings the calibre has been enlarged, at five and one-eighth inches, from 9 mm. to 20 mm., with very slight tendency to recontract, with no pain, hemorrhage, or other inconvenience than a slight though temporary increase of discharge after each sitting.

Twenty cases of stricture of the urethra have been treated by electrolysis during the winter. Three cases out of the twenty did not improve in any appreciable degree, and the treatment was changed. As the result of my experience in the other seventeen cases, justice compels me to give expression to the following conviction regarding the application of electrolysis to the treatment of urethral stricture:

First.—Many cases of stricture of the urethra, especially those of a fibrous nature, can be more effectively relieved by the action of the galvanic current applied locally, after the manner recommended by Dr. Newman, than by either gradual dilatation, divulsion, or internal urethrotomy.

According to my experience, all strictures are not alike susceptible to this treatment, any more than all cases are susceptible to treatment by dilatation. A larger experience, however, may change this opinion. My most successful cases, thus far, have been those in which the fibrous element predominated. Elastic and resilient strictures of large calibre have not yielded as readily to electrolysis as they have to the dilating urethrotome. Not the least advantage of this method of treatment lies in the fact that, when judiciously employed, according to the views so concisely and intelligently laid down by its author, no harm can come to the urethra, and so, if this method fails, we can fall back upon other and more radical measures.

Secondly.—The operation, while radical and effective, is conservative and physiological.

It aims at producing its results by methods that are strictly physiological, and never by cauterization or other destructive agencies. In this I must join with Dr. Newman in taking exception to the somewhat remarkable opinion of the action of electrolysis as expressed by Dr. F. O. Marsh (*Cincinnati Lancet and Clinic*, 86., N. S. XVII., 184–6). "Electrolysis," he says "means cauterization, and therefore I condemn it." "The idea that tissue is melted down in cartilaginous or any other structure without producing excoriation of the parts is a delusion; since electrolytic action takes place only at the surface of the electrode and the effect when obtained, though ever so slowly, must be identical with that of a caustic or red-hot bougie bored through the stricture."

In truth, the effect of galvanic action upon living tissue is far from being uniform. Everything depends upon the method of its employment and the direction and intensity of the current employed. A current may be so passed as to vary in its effect through every possible shade of difference, from a gentle stimulant to blood-vessels and capillaries to the most potential galvano-caustic effect.

Galvanization does no more necessarily imply tissue destruction or cauterization than it does in its multifarious applications in the arts imply conflagration. The practice of causing absorption of scars and cicatricial tissues by galvanism antedates considerably its application to the treatment of urethral cicatrices. So far as the *rationale* of the treatment is concerned, urethral electrolysis is simply an ingenious application of well-established galvanic principles. Just how the galvanic current acts in dissipating urethral contractions, unless it is through a process of absorption, never having had an opportunity of examining the process microscopically, I do not profess to know. Neither the endoscope nor the bougie throw any light on the interesting physiological processes that are set in operation by the galvanic current; the effect, however, is readily demonstrable and unimpeachable.

Thirdly.—The operation is painless and bloodless.

Not the least satisfactory feature in the galvanic treatment of urethral stricture is the immunity from hemorrhage. urethral abscess, urinary infiltration, blood-poisoning, and probably urethral fever, which this method presents in comparison with the older methods.

While no one doubts that infinite damage may be done by the careless or incompetent employment of electrolysis, yet I doubt exceedingly if the injury could be much greater than that which, in equally incompetent hands, may be inflicted by any cutting instrument, and especially by that most perfect and beautiful of them all, the dilating urethrotome. Yet, who of us who know and value this instrument would be willing to sacrifice the absolute precision with which we operate, because of the blunders and injury it has inflicted in ignorant and brutal hands?

The principles of electrolysis as applied to the treatment of urethral strictures, and as enunciated by Dr. Newman, are so clear, simple, and definite, that no one can follow them without appreciating their *cleverness*, or practise them without success. The astonishing thing to me is the fact that they have been so long before the profession without their value being more generally recognized. I apprehend one reason of this lethargy is due to an unwarranted skepticism as to the remarkable results obtained. Another reason, doubtless, is the discouraging inferences one might legitimately draw from the behavior of the urethra after the first and second application of the current—the temporary congestion, swelling, and pain on micturition, which sometimes occur.

In this city, I regret to say, but few of our leading surgeons, if any, have expressed confidence in the method. Throughout the South and West the operation is slowly establishing itself. In England Berkeley Hill and Buckston Brown, both men of matured and excellent judgment, have expressed their skepticism of its feasibility, while, on the other hand, Mr. Stevenson says, "the treatment of stricture of the urethra by this method is the most simple and striking in its results." Swinford Edwards says, "I cannot but think that a great future lies before this method." Bruce Clark says, "I have relieved cases better than could be done by any other method." S. T. Anderson (*Lancet*, 1885, ii., 1040) reports four cases cured, two in one sitting of twenty-three and three minutes, respectively. Hayes ("Transactions of Academy of Med., Ireland. 1886") reports three successful cases.

I am unacquainted with any efforts that have been made in this line in either France or Germany.

Professor William T. Belfield (*Journal American Medical Association*, 1886) summarizes his conviction, after an experience with thirty-seven cases, in these words: "I now use it (electrolysis) almost exclusively, except for stricture within an inch of the meatus and for stricture of large calibre situated elsewhere in the penile urethra. I consider the following to be its advantages:

"1. It is applicable to stricture in any point of the urethra.

"2. Any stricture or succession of strictures, however rigid and cartilaginous, however long and tortuous, however tight, even if impermeable, can be readily and safely perforated.

"3. As a rule it causes no pain or bleeding, is followed by no chill or urethral fever, and is always devoid of danger.

"4. When properly performed it can produce no false passage or other local lesions.

"5. The effects are more enduring than either those of cutting or stretching."

The above deductions of my friend, Professor Belfield, as well as the principles of treatment enunciated by Dr. Newman, have my unqualified approval.

A RARE FORM OF VASO-MOTOR DISEASE.

A CONTRIBUTION TO THE STUDY OF HYDROPS INTERMITTENS ARTICULORUM.

By A. H. FRIDENBERG, M.D.,

NEW YORK.

In the following paper I wish to present a form of joint disease which claims interest not only from the fact of its rarity, but likewise because it has in most instances resisted treatment, and because the present cases are, as far as I have been able to determine, the first of their kind to be recorded in this country.

Mrs. S——, a young married woman, twenty-two years of age, came to me during the month of May, 1885, to receive advice regarding a certain peculiar and obstinate affection of the knee-joints, of several years' standing. A brief inquiry into the nature of the complaint made me aware that I was to observe a remarkable and rare form of disease. The patient furnished the following details: She had always enjoyed good health, although never very robust. The flow became established between her fourteenth and fifteenth years, and at about the same time the present trouble appeared. This consisted in the development of a painful swelling of the right knee-joint, preceded by considerable pain, of a dragging character, in the right inguinal region, and attended by stiffness, heat, and tension in the joint, the circumference of which rapidly increased in size, and so remained for a certain number of days. This attack was sufficiently severe to confine the patient to her bed for three days out of the five that it lasted. Its progress was rapid, and it reached the greatest degree of intensity on the third day, subsiding gradually. A fortnight of perfect health followed, with restoration of the use of the limb, when the attack was repeated in the same joint and in precisely the same manner as before, but with greater intensity. Still another fortnight elapsed, counting from the last day of the previous attack, and with the advent of the fourteenth day a third attack, similar to the preceding, was ushered in. This lasted about six days, and at its termination was immediately succeeded by another attack, now affecting the left knee-joint, developing in the same manner and lasting five days. During the third, fourth, and fifth paroxysms both knee-joints were affected; the left always upon the subsidence of the swelling in the right limb, but not to the same degree. Each successive attack occurred with increased intensity, until, at the sixth attack, both knee-joints were equally affected. The seventh attack, however, was limited to the right knee, and the eighth, fourteen days later, to the left. Since that time the attacks have recurred with remarkable regularity, alternating from one knee-joint to the other, for seven years. The patient could foretell the appearance of each attack to the day, almost to the hour. It appeared precisely on the twenty-first day from the date of the first day of the preceding attack, and lasted exactly seven days, thus leaving an interval of fourteen days of perfect freedom. Finally, in her twenty-second year, the patient married. To her great gratification, the attack following this event, which was due on the twelfth day day thereafter, was extremely transitory and mild, and with the next return of the twenty-first day, it failed entirely to put in an appearance, and remained absent from that moment and during the whole period of her pregnancy. The patient nursed her child for two weeks; she again became pregnant four months later, having menstruated regularly in the interim. A second child was born, and six weeks later the attacks, which had not recurred since marriage, reappeared. At first they were mild, but they grew in intensity and recurred regularly during lactation, during the absence of the menses, and afterward, as well. Almost every conceivable method of treatment had failed to conquer this disease. During seven years the patient had subjected herself to compression, counter-irritation, inunction, massage, vesication, and had tried numerous internal remedies without avail. Aspiration had finally been resorted to. The right joint had been evacuated three times before marriage, and the left twice since the return of the affection after marriage, and about a tablespoonful of straw-colored, gelatinous fluid, of the consistence of white of egg, had escaped, and continued to flow from the puncture for half an hour afterward. Since the attacks have returned they have become altered somewhat in rhythm. Instead of recurring as before, at stated regular periods of twenty-one days, they now appear every twelfth day. At first the left knee-joint alone was affected, just as at the beginning of the malady seven years ago. But after the third attack the right knee-joint also became implicated, swelling up immediately after the subsidence of the process in the left joint. During the fourth, fifth, and sixth attacks, both joints were affected in immediate succession. The seventh attack, however, was limited to the left knee, and since then, and up to the time of this writing, the right knee-joint has not again participated. The attacks now last about six days, are quite distressing, and prevent walking. They are still preceded for two days by violent dragging pains in the groin, at the same time a certain degree of general languor and complete anorexia is experienced. There is no febrile movement, no headache, and no pain in any other joint. The patient is deprived of the use of her limb for about three days, and the pain is usually severe enough to prevent sleep. The last attack ended three days ago.

The peculiarities of the case, as described by the patient, were such as to raise some doubts in my mind as to the accuracy of her observations. I had not then read of anything analogous, and the text-books at my disposal failed to enlighten me on the subject. The patient was a slight, pale, and delicate-looking person. My first impression associated a strong flavor of hysteria with the history. I directed the patient to send for me at the onset of the next attack. Several days later I was summoned. It was the second day of the attack. The patient was reclining on a lounge, unable to walk. The left knee-joint was decidedly swollen, there was distinct elastic resistance to the touch, the fluctuation being limited to the capsule of the joint. The natural depressions at either side of the patella were effaced, and the fluid contents of the joint could easily be displaced upward, by compression, into the subcrural pouch. Ballottement of the patella was readily produced. There was moderate limitation of the excursions of the joint on passive motion, due to the mechanical distention of the capsule. Active movements were slowly and cautiously executed, and caused much discomfort. There was appreciable tenderness on pressure only at one point, viz., just over the inner aspect of the head of the tibia, at the insertion of the int. lat. ligt. On the following day the affection had reached its acme. The manifestations were the same, but they were more marked. The distention of the capsule was such as to render it quite tense; the pain was distressing; there was decided muscular resistance to any attempt at moving the joint. The hand applied to the surface detected an increase in the temperature as compared with the sound side. The circumference of the affected joint measured fourteen and three-fourths inches, that of the other twelve inches. The patient had retired to bed and was obtaining slight relief from the application of ice. She could not bear to walk a step. On the fourth day there was a decided diminution of all these symptoms, and on the fifth day the patient was able to walk with the aid of a cane. On the sixth day she was able to come to my office. An examination of the joint then failed to detect the slightest abnormality other than a difference in circumference of about one-fourth of an inch. The movements were perfect in every direction, and the bony contour of the joint was that of the normal limb.

My second case of this interesting affection was met with in the person of one Max W———, German, thirty-one years of age, during December, 1887. Unfortunately he was a dispensary patient, and did not fulfil his promise to report at regular intervals for observation. His history, however, in brief, was as follows: No hereditary influences. Never had been ill until 1875, when, after an unusual muscular effort in lifting, he claims to have "sprained" his left knee-joint. Two days later he noticed a painful swelling, which lasted eight days, during which time he could not bend the knee, nor ascend the stairs. He was then quite well for five days, when the swelling recurred again, lasting eight days. This series of joint attacks has recurred regularly during the past twelve years. The intervals now run from ten to fourteen days. On two occasions, four years ago, the attacks appeared in the right knee, instead of the left. The attacks are always preceded for two days by pain in the right groin, which interfere with walking in the erect posture. Patient was under Nussbaum's care in 1876. The nature of the disease was evidently overlooked at the time, since local treatment was resorted to almost exclusively; no improvement followed upon vesication, leeches, iodine, and immobilization.

Here was presented, in brief, a regularly recurring acute synovitis of a joint. The periodicity of the affection constituted its chief and most interesting feature. The patient had never had any serious ailment. There was no appreciable evidence of organic disease, either in the heart, lungs, kidneys, or other organs. There was no history of syphilis, malaria, rheumatism, or gout. I was at first inclined to admit malaria as a factor in the peculiar manifestations in the first case; but, aside from the lack of any clinical evidence to support the assumption, the patient assured me that she had been, on that same supposition, treated for a long while with large doses of quinine, absolutely without the least benefit.

Reference to the standard works for elucidation of the subject was not satisfactory. I was surprised to find absolutely no mention of this remarkable disorder in most of them. Gross, "System of Surgery" (edition of 1882) contains not a word of the existence of such an ailment. Barwell, "On Joint Diseases" (1881), is equally silent. Sayre's "Orthopedic Surgery and Diseases of the Joints" contains no mention of the subject; nor does Holmes' "System of Surgery" (1872), Erichsen's "Surgery" (1878), Gibney's "Diseases of the Hip" (1884), "Bryant's Text-Book of Surgery" (1881); Billroth-Pitha, "Lehrbuch der Chirurgie" (1882); article on joint diseases by Volkmann; Albert's "Lehrbuch der Chirurgie" (Vienna, 1884); Koenig's "Lehrbuch der Chirurgie" (1876); Ashhurst, "International Encyclopædia of Surgery," edition of 1884; (Barwell), Bardeleben, "Chirurgie," edition 1867; Vidal's "Pathologie Externe," Paris, 1861; Ziemssen's "Cyclopædia of Medicine," first edition; and this in spite of the fact that finally, in Hüter's "Klinik der Gelenkkrankheiten." Leipsic, 1877, I came across a half-page article on the subject, embodying six cases. To these I shall recur later on. In Holmes' "System of Surgery," revised edition, 1882, vol. iii., page 240, the following brief note occurs:

"Seiligmuller mentions a hitherto undescribed affection of the joints, an intermitting hydrops articulorum, usually affecting the knee, more rarely the hip. In the majority of cases a swelling appears without febrile symptoms, and from no known cause, and disappears, reappearing after a certain interval. The duration of the attack is usually four days, and the pause between the attacks from eight days to a fortnight. No treatment seems to be of avail." In the "Deutsche Chirurgie," edited by Billroth and Lucke, the most recent standard work on surgery of Germany, the chapters on diseases of the lower extremities (by Busch) had not as yet appeared in print. The chapter on diseases of the upper extremities, however, contains mention of one case, by Vogt, of hydrops intermittens of the elbow-joint. A bare mention of the existence of the disorder appears in Erb's "Handbuch der Elektrotherapie" (1882), and also in the latest edition (1885) of Koenig's "Surgery." Ross' "Diseases of the Nervous System" (1883), contains no mention of the disease. Strümpell's last edition mentions the affection, and devotes but a few lines to it. A systematic review of the current literature of the last twenty years was productive of more satisfactory results, and is embodied in the collection of the records of the following twenty-three cases, which, with my own, make twenty-five.

Case I.—C. H. M——: "Periodical Inflammation of the Right Knee-joint" ("Transact. Medico-chir. Society, London, 1867," p. 21). A female, forty-three years of age, received into the Middlesex Hospital in 1852, was the subject of recurrent swellings of the right knee-joint for nineteen years. In the beginning the periods were of thirty days each, later on the rhythm changed to eight days. Each attack lasted five days. The attacks ceased spontaneously in the third month of pregnancy and returned three months post partum; at eighteen years of age the patient had had ague for six months. In this case quinine in very small doses, and arsenic, proved unavailing. In point of time the menstruation was quite independent of the attacks.

Case II.—A female, twenty-one years of age, was received at the Middlesex Hospital in 1865; she had periodical swellings of the right knee-joint every twelfth day, each attack lasting five days. They were usually ushered in by shooting pains in the leg and thigh. Her menses were regular and natural, and independent of the attacks. Treatment by quinine and arsenic. The attacks became successively less severe and more irregular; she had six or eight more after leaving the hospital, and was then lost sight of.

Case III.—Lowenthal (*Berl. klin. Wochenschr.*, 1871, No. 48) observed this disease in a female, thirty six years of age, who had married at the age of twenty-two. The first attack occurred in her twenty-ninth year. The right elbow-joint was affected at first, and for six months was the seat of periodical swelling, recurring every three weeks, each attack lasting three days. During these periods, but not at any other time, she suffered with palpitation of the heart and exophthalmos, and her extreme anæmia, due to the profuse menstruation, gave her the appearance of one afflicted with Basedow's disease. She had never had malaria. During an intercurrent pregnancy the attacks ceased altogether. Two years later they reappeared in the left knee-joint every thirtieth day, and later on every twelfth day. Treatment with iron, quinine, the iodides, etc., failed to give any relief.

Case IV.—Bruns (*Berl. klin. Wochenschr.*, 1872, No. 1), records the following case: A domestic, aged twenty-nine, had had recurring attacks of swelling in the right knee-joint every eleventh day for nine years, each paroxysm lasting six days, with intervals of perfect health of five days. The initial attacks were preceded by a general but slight febrile disturbance, but later on they were not. The attack consisted essentially of a rapid swelling up of the joint, caused by a serous intracapsular effusion into, and limited by, the capsule, without inflammatory signs and with very slight tenderness on pressure. The subjective symptoms were those of a feeling of weight and stiffness in the limb, with disability. The patient now began to menstruate until her twenty-fourth year, and her periods stood in no relation whatever to the time of appearance or the intensity of the attacks. She had been under treatment at various times. Quinine had seemed to produce a temporary amelioration. Bruns applied compression to the joint by elastic bandages both before and during the attacks, without avail. The exhibition of doses of quinine, ranging from nine to thirty grains daily, during a period of six weeks, reduced the attacks to a mean duration of four days. The actual cautery was applied to both sides of the spinal column without success. A very prompt improvement followed the administration of Fowler's solution with cinchona. The patient was cured in five weeks and remained so for twenty months, when a relapse occurred; a repetition of the same treatment was again followed by a prompt cure.

Case V.—Grandidier (*Berl. klin. Wochenschr.*, 1872, No. 22.) records the case of a man, forty-four years of age, of gouty habit, who had been affected with swelling of the right knee-joint, recurring regularly on every fourteenth day, and lasting six days for many years. Failing to obtain any relief from the most varied methods of treatment, he finally went to "Heundorf" and there took the sulphur-mud baths, whereupon the attacks ceased. He remained free for three years, when a relapse occurred. The renewed use of the sulphur baths this time was unavailing. The attacks continued in spite of them.

Case VI.—Grandidier (*loc. cit.*). The patient was a woman, fifty-four years of age. The attacks had appeared in the right knee-joint every eleventh day, in the manner described, for several months. Each attack lasted five days. She bore no evidence of any organic disease, never had had malaria, and her menses, which were regular, were in nowise connected with the attacks. Quinine was administered, with the result of reducing both the duration and intensity of the attacks, but a cure was not effected.

Case VII.—Roser (*Centralblatt f. Chir.*, 1874, No. 25). A young and healthy man, aged seventeen, was seized with an acute swelling in both knees, when fifteen years of age. The attacks lasted two days, and recurred on the eighth day, and from that time regularly every eighth day for two years; both knee-joints were affected, sometimes simultaneously. Each individual attack lasted two to four days, and was followed by an interval of perfect health. His general condition was good, the pain was only moderate. Rest in bed, plaster-of-Paris dressing, compression combined with iron, iodides, quinine, arsenic, and ergotine, were employed without benefit.

Case VIII.—W. Bylicki (*Centralbl. f. Chir.*, 1874, No. 38). A healthy man, thirty-one years of age, experienced an attack of heat, swelling, and stiffness in the right knee-joint, which lasted six days, and then disappeared without any injury to the joint whatever. After an interval of perfect restoration the attack was repeated at the end of seven days, and from that time it regularly appeared every thirteenth day, for a year, when the disease passed into a chronic condition of hydrarthrosis of the joint. Various remedies, internal and external, failed to ameliorate matters.

Case IX.—Hüter ("Klinik d. Gelenkk.," 1877, p. 188) mentions a case observed by him in 1876, without giving any particulars as to rhythm or duration. He gradually effected a cure, after several months, by repeated injections into the knee of a solution of carbolic acid just prior to the expected onset of the paroxysm. They became irregular, then rare, and finally ceased altogether.

Cases X. and XI. are recorded by Jousset in the *Art Médical de Paris* for 1877, a journal to which I could not obtain access.

Case XII.—Panas ("Bulletin de la Soc. chir. de Paris, Séance du 27 Mars 1878") saw this affection in a young woman, twenty-two years of age, who had never had syphilis, rheumatism, or malaria; the attacks commenced in her seventeenth year, lasted four days, occurred in both knee-joints simultaneously, and had recurred every fourteen days for four years; they had suddenly ceased, and remained absent during two successive pregnancies, only to return, in one case six weeks after the birth of the child, and in the other two weeks after a miscarriage in the fourth month of gestation. Panas claims to have detected dry crepitation in various other joints, notably that of the ankle, wrist, elbow, and those of the fingers. During the attacks, and after the disappearance of the effusion, there was a certain amount of thickening and dry crepitus in the capsule of the knee-joint. Treatment by mercurial inunction, the iodides, vesication, massage, elastic compression, and quinine was quite ineffectual.

Case XIII.—Verneuil ("Bull. de la Soc. chir. de Paris," 1878, No. 3) observed a case occurring in a young woman twenty-five years of age, who had been a sufferer for many years. She had been under Nélaton's care eight years previously, and was said to have been cured by him with quinine. A relapse took place seven years later. Quinine was ineffectual, compression likewise. An intervening pregnancy cut short the disease. It returned six weeks after delivery. Discussion of the case at the meeting of the Society brought out the fact that it was probably identical with the one presented by Panas.

Case XIV.—Verneuil (*loc. cit.*) also recollected a second case, which he had observed some years previously in the person of a young woman, twenty-seven years of age, the particulars of which were embodied in the inaugural thesis (Paris, 1877) of his pupil, Dr. Ragan, together with the records of two other cases, observed by Canonne and by Le Denta.

Case XV.—Le Denta (*Gaz. des Hôpitaux*, April, 1878) described the condition as he had observed it, in 1856, in the person of a young man, sixteen years of age. The attacks occurred every fourteenth day, and lasted nine to eleven days, involving the right hip, and seven years later the left knee-joints and ankle-joints. Various internal remedies failed to give relief, likewise inunctions and injections of tr. iodine. Cauterization of the surface, with immobilization of the joints, had brought about a temporary cure. At any rate, the patient was discharged from the hospital and did not return.

Case XVI.—Canonne (Virchow-Hirsch "Jahrb.," 1868, vol. ii., p. 390) details a case of intermittent dropsy of the right knee-joint, following an acute inflammatory swelling of the right ankle, in the person of a domestic, twenty-seven years of age. Each attack lasted four days, and recurred regularly on the thirteenth day for nine months. The most varied treatment was unavailing.

Case XVII.—Perrin (*L'Union Méd.*, 1878, No. 61) states that in 1845 he published, in the second volume of the *Journ. de Médecine de Trousseau*, an account of a case which he then entitled "Cas curieux de contracture partielle intermittente à type octane, avec irritation violente et épanchement de sérosité dans plusieurs articulations." The patient in question was a man, in his forty-eighth year, who had had chronic rheumatism of the left shoulder-joint for several years. Four years previously he had had intermittent fever of the quartan type, which, after six months' duration, had disappeared spontaneously. The patient complained that for the past six weeks he had been seized regularly once a week, during the night from Friday to Saturday, with a moderate rise of temperature, ushered in by mild chills, and followed by a gentle perspiration. Simultaneously the forearm became slowly and gradually flexed upon the arm, which again became firmly drawn to, and held against, the chest; the elbow-joint seemed almost anchylotic, and resisted all attempts at extension. The tendon of the biceps felt like a hard, tense cord; the fingers were firmly flexed into the palms of the hand. During the attack the patient experienced a painful prickling in all the joints of the right extremities. Two or three hours later he noticed an œdematous puffing up of the elbow, the knee, and the interphalangeal joints of the fingers and toes, without heat or redness. After a few hours a considerable intra-articular swelling invaded the knee- and elbow-joints, which was completely gone after the lapse of three days. The contraction of the upper extremity generally lasted until the effusion into the joints had reached its acme, and then generally disappeared together with the fever. A cure was obtained, after one or two attacks, by quinine and belladonna.

Case XVIII.—Seelig Mueller (*Deutsch. Med. Wochenschrift*, 1880, Nos. 52 and 61). A manufacturer, aged forty-nine, had had intermittent fever for seventeen weeks some years previously. For twenty-four years he had had attacks of dropsy of the right hip-joint and of the left knee-joint alternately, recurring every twelfth day, each *attack lasting about* a day and a half. *Without treatment* the attacks ceased, but recurred six years later, lasted three months, and then again failed to appear for four years. They then returned in the fall and lasted till spring, mostly always invading the left knee-joint, and only occasionally the right hip. Six years later, relapse, affecting the left knee-joint for a short time. Three years later another relapse, this time limited to the right hip-joint, with very acute pain, but without distinct evidence of swelling. Three years later another relapse, affecting both hip-joints for a period of three months. In the month of July, 1879, the left knee-joint again became affected, after a respite of seven years, and from that time on attacks followed every twelfth day for two months. Then a change in the rhythm took place, in such a manner that for every two attacks invading the left knee, one involving the right, and one the left hip-joint, was interpolated, each of three days' duration. There had never been any febrile reaction. The circumference of the left knee-joint, at the acme of the swelling, showed an increase of nine ctm. as compared with that of the sound limb. A slight difference in circumference, amounting to one-half to one ctm., generally remains during the interim, with a noticeable thickening and effacement of the contour of the joint, but no pathological intra-articular alteration can be detected. Treatment by the administration of quinine, salicylic acid, and the use of ice, electricity, and carbolic-acid injections, was fruitless.

Case XIX.—Pletzer (*Deutsch. Med. Wochenschr.*, vol. vi., 1880) records a case of recurring dropsy of the right knee, which he observed during a period of twelve years in the person of a woman, forty years of age, the mother of seven children. The attacks commenced during the menstrual period in the eighteenth year, and returned every three months; the first attack was attended with febrile disturbance and with local surface heat. In all the attacks the pain and inability to use the limb were marked. She had never had rheumatism or intermittent fever. Electricity, baths, and various internal remedies aggravated the condition and brought about an increased frequency in the appearance of the attacks, which soon developed into an eighth-day rhythm. In the eighth year of the affection a general deterioration of the patient's condition was manifested by attacks of palpitation (130 to 160 pulse-beats a minute), uneasiness and anxiety. The patient became emaciated; a soft systolic murmur accompanied the first cardiac sound, and swelling of the thyroid gland, exophthalmos, conjunctival injection; in short, symptoms of Basedow's disease supervened, and with them the dropsical attacks disappeared. They returned four months later, with a rhythm of eleven days, whereupon a marked improvement in the patient's health was noticed. In spite of the many attacks, the right knee-joint showed no structural alteration whatever, and during the intervals the difference in the circumference of the two joints did not exceed one ctm. The menstrual periods stood in no relation whatever to the attacks, and their progress was not interrupted by a pregnancy occurring in the patient's thirtieth year, whereas in a subsequent pregnancy, in the thirty-ninth year, the attacks suddenly ceased, and remained away during the whole period of gestation. Two months after childbirth, symptoms of Basedow's disease again appeared, but finally subsided on the recurrence of the dropsical effusion, some weeks later, upon which the patient's health seemed to undergo a marked improvement. Of many and varied forms of treatment, arsenic alone proved partially serviceable.

Case XX.—Kolbe (*Deutsch. Med. Wochenschr.*, vol. vii., No. 4, 1881). A maiden lady, thirty-two years of age, of anæmic habit and of inherited nervous tendencies, met with a trifling accident to her left knee in her twenty-fifth year. This was followed by a swelling of the joint, which proved to be an intra-articular exudation, lasting, with intervals of improvement, six months. One year later the swelling reappeared, without appreciable cause, in the left knee-joint, and from that time regularly every ninth day, each attack lasting three days, and causing neither pain nor constitutional disturbance. Remedies directed to the alleviation of the marked anæmia resulted in a diminution of the number of attacks, and a gradual lengthening of the intervals of health. At the end of six months the attacks had ceased. Two years later a relapse occurred, of but one week's duration. One year later another relapse occurred, lasting one year, the attacks appearing every eleventh day. There was no evidence of organic disease. The left leg presented marked muscular atrophy and some thickening of the knee-joint about the ligamenta alaria, and the patient complained of a weakness and trembling in the limb whenever she attempted to walk. The repeated use of the induced current restored the tone of the muscles. A water glass immobilizing bandage was applied and the attacks ceased within five weeks.

Case XXI.—Pierson (*Deutsch. Med. Wochenschr.*, 1881, No. 7). A healthy and well-developed girl, eleven years of age, has been repeatedly attacked with swelling of various joints, accompanied by extreme pain and complete functional disability, during the past two years. At first they recurred every three or four weeks, lasting four days. After a year, they had become of so frequent recurrence that the child was free from suffering only for a single day at a time. The wrist and the ankle-joints were most frequently seized, but not rarely all the joints were included, occasionally even the cervical vertebral articulations. There had never been any typical regularity with regard to the time of occurrence; the longest interval between two attacks was but six days. The disease resisted all therapeutic resources, including arsenic. Local faradization caused violent pain, but was ineffectual. Galvanization of the spinal column, combined with the internal administration of arsenic, brought about a marked improvement within six months. The intervals between the attacks became much more prolonged, and the latter were far less severe.

Case XXII.—Fiedler (*Deutsch. Med. Wochenschr.*, 1881, No. 3). A woman, twenty-five years of age, had had periodical swelling of the joints for the last thirteen years; the disease commenced in the left knee-joint, which was the seat of attack for two consecutive years, every twelfth day, each attack lasting three days. After two years the right knee-joint occasionally shared in the affection, and several months later both elbow-joints and likewise the wrist- and the hip-joints became involved in the regular round of dropsical attacks, the whole period of which now consumed twelve days. When the disease had been in existence eight years, a change to a ten-day rhythm took place, possibly due to exposure to cold, and from this time forward with each attack all the joints became involved simultaneously. Fiedler improved his opportunities to watch the course of the affection in thirty-three successive attacks, which occurred with intervals of but two to four days, each lasting nine days. Later the joints became affected in regular succession. They commenced with a burning sensation in the eyes, and with conjunctival congestion. Then the swelling and pain would affect the joints successively in the following order: First, the right hip-joint, and on the following day the left; on the third day the right knee (half a day later, occasionally, the left knee); on the fifth day the swelling in the right knee would subside, only to appear in the left elbow, and half a day later in the left wrist-joint, with hyperextension of the hand, and simultaneously in the metacarpo-phalangal articulation of the left thumb, finally completing the circuit with the right elbow- and wrist-joints. On the seventh day, complete restoration of all the joints to the normal condition. On the tenth day, renewal of the regular succession of attacks. The menses had always been irregular, but there was no evidence of organic disease. She had been subject to certain forms of nervous paroxysms since her twelfth year, which were characterized by fainting spells, followed immediately by an icy coldness and pallor of the skin of short duration, and succeeded by a rapid rise of surface-temperature and profuse perspiration. These paroxysms generally terminated with retching and vomiting.

Case XXIII.—Vogt (*Deutche Chirurgie*, Part 64, p. 199). "A female, aged thirty-two, had attacks of swelling of one or both elbow-joints, with much pain and functional interference, every ninth day. The attacks were generally coincident with the menstrual periods." Further particulars are not given.

Case XXIV. is reported in the *Centralblatt f. Nervenheilk.*, No. 5, 1886, a journal which I could not secure.

There are thus, including my two cases, twenty-six cases on record at present.

We have here a series of cases illustrating a peculiar and interesting disease, the main characteristics of which may be briefly summed up as constituting a serous exudation into one or more joints, arising without appreciable cause, and recurring and subsiding spontaneously at certain definite periods. A comparison of some of the leading features serves to concentrate the attention upon those presented in common. These are mainly suggestive of involvement of the vaso-motor system. Palpitation, attacks of syncope, exophthalmos, rigors, and transpiration find mention in five cases. The symptoms of Basedow's disease are fully developed in two cases. Various emotional disturbances, depending perhaps upon the marked anæmia, are emphasized in others. The remarkable influence exerted upon the course of the disease by the intervening pregnancies must not be overlooked, although a satisfactory explanation is impossible. In eight out of nine recorded pregnancies occurring in the course of the disease, a complete cessation of the attacks, from the conception until an average period of six weeks post partum, is noted. There does not appear to be any causal or periodic relation between the occurrence of the attacks and the menstrual function, although in several instances the attacks originated at about the period of its establishment. This may be a mere coincidence, or may be regarded as an expression of the peculiarly impressionable state of the nervous system in females at the period of puberty, and not as in any sense an implication of the function. In fact, in Case V. we find the origin of the disorder antedating the first menstrual molimen by four years, and special mention is made, in the majority of the cases occurring in females, of the fact that the attacks occurred independently of the catamenial period.

The question as to the nature of this interesting disorder can only be answered in a general manner. We need not hesitate to look upon it as a neurosis of vaso-motor origin. But we shall be at a loss to define its exact pathology, and even an approximate idea of the seat of lesion can only be a matter of conjecture, not only on account of the imperfect state of our knowledge of the vaso-motor origin and distribution, but because no case has so far reached an autopsy. This much we are justified in concluding: knee-joint swellings are of vaso-motor origin. They must be produced by serous exudation from the capillaries of the synovial membrane. In the absence of any permanent disability or injury to the joint or involvement of the deeper structures, we may assume a non-inflammatory change in the vascular blood-pressure and consequent dilatation of the arterioles, due either to stimulation of the dilating or paralysis of the contracting vaso-motor nerve-fibres in the vessel-walls. As the vaso-motor contraction or tones of the arterioles is the more constant and uniform, this latter is probably interfered with or inhibited. Thus dilatation of the capillaries persists, permitting active transudation. When the lost influence of the nerve-fuuction is re-established, the vessels resume their normal tones, and the equilibrium between secretion and reabsorption is readjusted. The excess of fluid is absorbed as rapidly as produced. This exudation is not of an inflammatory nature. The pain and disability are due to a rapid mechanical distention of the capsule only. It is therefore a passive dropsy, and its transitory character a clinical reflection of a similar process in the nerve-centres. We can hardly picture to ourselves pathological changes in the central nervous system of a transitory nature otherwise than as the result of a disturbance of the vascular supply of the area involved, leading to exudation, œdema, and compression of the surrounding nerve-tissue. Vaso-motor disturbances are characterized by rapid changes in the calibre of vessels, thus favoring local congestions or ischæmias. These central changes must be supposed to subside spontaneously, or be in some manner checked before developing sufficiently to constitute a permanent lesion. Can such central disturbances produce joint swellings? When we consider the intimate connection of arthropathies with certain forms of organic spinal disease, with which we have become familiar through Charcot, Weir-Mitchell, Esmarch, Shaffer, and Gibney, we need not doubt the occurrence of temporary joint disease as a possible consequence of transitory central disturbances. Long before Charcot's writings, Dr. J. K. Mitchell, of Philadelphia, cured a persistent case of subacute "rheumatic" synovitis in a woman with an angular curvature, after failure of all the usual remedies, by treatment for spinal inflammation. He subsequently treated three similar cases with the same success. He concluded to regard rheumatism as a spinal neurosis.

Perhaps the most interesting feature of this joint disorder, apart from the mystery of its pathological significance, is its periodicity. It would hardly lead to more than an unprofitable speculation, exceeding the natural limits of this paper, to endeavor to find a physiological interpretation. Yet it may not be uninteresting to point out that vaso-motor disturbances are frequently characterized by periodicity. Witness the recorded instances of periodic acute congestions and œdemas of various parts of the body, of attacks of migraine, of regularly recurring paralyses, notably of monoplegia of the oculo-motories, of which nine cases have but recently been recorded by Hasner and Moebius (*Schmidt's Jahrbucher*, No. 9, 1885), and more recently by Hinde (MEDICAL RECORD, October 22, 1887); likewise the instances of periodic attacks of vomiting, not of hysterical origin, such as are reported by Struebing (*Zeitschr. f. klin. Med.*, vol. ix., 1885), by Leyden (*ibidem*, vol. iv., p. 605), and by Charcot as "crises gastriques," both as complications of spinal disease and independently of the latter. Periodicity may, therefore, be regarded as a possible expression of a transitory circulatory disturbance in the central nervous system, more particularly, perhaps, of those areas, whether in the brain, the cord, or the sympathetic ganglia, with which the vaso-motor tracts are connected. No satisfactory physiological interpretation of "periodicity" is possible at the present day.

We must content ourselves with the most plausible view, that it may be a perverted vaso-motor function, impressing a certain type on certain disorders, originating in temporary vascular disturbances in the nerve-centres.

We are more familiar with periodicity under another garb. It has come to represent to many the one constant and unvarying feature by which to detect the manifold disguises which "malaria" may assume. But our very familiarity with periodicity, mainly as a characteristic of malarial explosions, is misleading to many minds. Periodicity and malaria are synonymous. We are too prone to lay at the door of "malaria" all obscure affections of which periodicity is the salient feature. This accounts for the uniformity with which quinine is mentioned as having been administered in almost all of the cases of intermittent joint dropsy. Its failure to act demonstrates conclusively the non-malarial origin of this affection, and likewise the existence of periodicity independently of any malarial basis. Periodicity is not the exclusive trade-mark of malarial disorders any more than are chills and perspiration, although the phenomena may depend upon the same variations in the intra-vascular blood-pressure. Periodicity is the characteristic expression of vaso-motor disturbances in general, of which "malaria" is simply one of the more familiar types, sharing its general manifestations, albeit having a distinct and peculiar bacterial origin. This latter characteristic explains why the quinine salts exert a decided influence upon one particular variety of periodicity, and fail to do so in others.

Other instances of periodicity attending vaso-motor neuroses are not wanting. As far back as 1817, we find three cases of regularly recurring attacks of vomiting, of definite duration, and separated by equal intervals of health, communicated by J. Adams ("Transactions of the Medical Society of London, 1817"). Of the cases of transient and recurring spinal paralysis, I will cite those recorded by Hartwig (*Centralbl. f. d. Med. Wissensch.*, No. 26, 1885), describing an intermittent and complete spinal paralysis, lasting twenty-four hours, with loss of tendon-reflexes, under observation in hospital for over seven months, without improvement; and by Westphal (*Berl. Klin. Wochenschr.*, No. 32, 1885), illustrating a similar case; the attacks being repeated every four to six weeks at first, and several times a week later on; and periodic attacks of paraplegia, observed by Zischl (*Prag. Med. Wochenschr.*, No. 42, 1885); none of these cases having a malarial basis, or being at all influenced by quinine.

As regards the treatment of my case, it consisted mainly in the employment of electricity. The improvement in the patient's general health was rapid, and was attended by a diminution in the frequency and the severity of the joint attacks. Electricity was applied in the form of the galvanic current to the medulla daily at first, less frequently later, the electrodes being placed upon the mastoid processes, and the strength of the current being cautiously regulated according to the patient's sensations, avoiding dizziness and flashes of light. After the third application of electricity, the patient for the first time was able to pass through an attack without taking to her bed, and was able to walk with the aid of a cane. After three months of treatment, the patient was not at all inconvenienced by the attacks, but was able to attend to her household duties throughout. Finally, after treatment extending over nine months, the attacks ceased altogether and remained absent for five months, during which time treatment was suspended. They then recurred, although much less severely than formerly, and have persisted, in a moderate degree and in an irregular manner, ever since, in spite of the energetic resumption of the treatment which at first produced such prompt amelioration. The use of electricity was supplemented by the internal administration of iron, arsenic, and mercury in tonic doses, occasionally by cod-liver oil, and by various hygienic measures in the way of cold sponging, open-air exercise, and generous diet. The rapid general improvement in the patient's condition was marked, and suggested the possibility of the existence of an inherited syphilitic taint, especially when a younger sister, fifteen years of age, who had a perforated soft palate, interstitial keratitis, and a chronic nasal catarrh of some years' standing, was brought to me for treatment.

The future investigation of these cases of periodic vaso-motor neurosis should not lack a special inquiry in the direction of syphilis hereditaria tarda.

At last accounts the attacks were recurring regularly every fourteenth day, although in so moderate a degree as not to interfere at all with the patient's comfort or her household duties. It is not impossible that a more systematic and persistent use of the galvanic current might have resulted in a complete cure.

Certainly, as the result of the electric treatment, the patient's present state is a very satisfactory one, when compared with that of former years. Judging by the observations of the writers cited, no other method of treatment with which we are at present familiar can be resorted to with a more rational prospect of ultimate success.

Clinical Department.

AN OBSCURE CASE.

By D. W. LONEY, M.D.,

OLENA, O.

A. A. F——, aged thirty-five, married, country store-keeper in good financial standing, and very ambitious for gain; has been liable to periodical attacks of drunkenness since boyhood, which in late years appear to have followed fits of despondency growing out of financial disappointments, howsoever slight. Owing to recent family trouble, involving him financially, he had of late been unusually despondent; in fact, his mind at times seemed to have been seriously affected. Had been troubled with persistent insomnia since the trouble came on him.

When drinking, he would swallow anything he could get hold of containing alcohol—patent medicines, flavoring extracts, etc.—keeping it up until his supply ran out, or his stomach refused to hold anything more, when he would sleep off the effects, and next day be ready for business again. On April 4th he began one of his sprees. Drunk again on the 5th, when he fell off a load of wood, from the effects of which accident he did not suffer at that time, or the day following. On the morning of the 6th he was apparently all right, and transacted some business in his usually shrewd manner. Later in the day, he drank freely of hard cider, and was helplessly drunk in the evening.

On the morning of the 7th he was somewhat delirious, and at times endeavored to take his own life. It was at this time that I was called to see him. Temperature normal; pulse, 85; headache and lumbar soreness. At times he seemed rational, but if left alone would relapse into a state of melancholia, or, at other times, he would be engaged in solving some perplexing business problem; failing this, he would pour forth a stream of malediction against the subject of his late mental disquietude. Large doses of sedatives would produce sleep for a short time, when on awakening he was more decidedly maniacal than before. He ate voraciously whenever he could get where food was. This condition lasted until the evening of April 9th, when he sank into a deep sleep, from which it was impossible to arouse him except by the persistent application of some painful measure. After being roused he would immediately relapse into his former lethargic condition, which only differed from natural sleep in that he could not be awakened. In response to questions pressed upon him at these times, he would give irrational answers. This condition lasted seven days. His temperature remained normal; pulse, 72 to 86; respiration, 20 to 26. Reflexes almost normal; cutaneous sensibility normal; sense of smell, taste, sight, and hearing but little if at all impaired. Pupils normal.

In the evening of the 16th his temperature rose to 101° F., which was accounted for by his having bronchitis. Fearing a hypostatic pneumonia, his position was frequently changed. From the 16th to the afternoon of the 19th his condition continued about the same—temperature ranging from 100° to 101½°, pulse and respiration corresponding; pupils continuing normal in their reaction to light. No signs of paralysis of any muscles. About 4.30 P.M. of the 19th, his temperature was found to be rising, and in three hours had risen to 103½°, when indubitable signs of pneumonia appeared. His temperature continued to rise until it had reached 108⅕° at 5 A.M., April 20th, when he died. A few hours before death he became insensible to all external influences. No post-mortem was allowed.

The interest in this case is the obscurity of the diagnosis. Was it a case of acute alcoholic mania, or was it delirium tremens, followed by a prolonged and fatal sleep? Was it the result of mental worry, the nervous system having been broken down by alcoholic excess? Did his fall on the 5th have anything or all to do with the case, some undiscovered cerebral or spinal lesion having existed latent, causing his condition?

There were no discoverable signs of paralysis of the ocular or other muscles from the beginning of his sleep to the time of his death. Family history discloses hereditary insanity.

During the first week of his lethargic state, he would eat and drink when aroused. His bowels were oversensitive to the effect of laxatives. Urine rather scant, but free from albumen and casts.

Although we had the best of local counsel we were unable to arrive at any definite diagnosis of the case.

RESUSCITATION IN THREATENED DEATH FROM CHLOROFORM.

By F. T. MILES, M.D.,

BALTIMORE, MD.

It being now generally conceded that the best means of resuscitating patients threatened with death during the inhalation of chloroform is to invert the position of the body, it is a matter of interest to consider how this change of position accomplishes the result aimed at. The explanation usually given, that the blood is sent in increased amount to the centres innervating the heart and the apparatus of respiration seems unsatisfactory, when we reflect that the cranial cavity is so nearly a completely closed one that the amount of its fluid contents can scarcely be expected to vary to any considerable extent through gravitation. Again, if the heart has ceased contracting, the effect of gravity will be principally upon the blood in the veins, diminishing its onward flow, and thus tending to arrest the movement of the blood in the capillaries. Now we know that stopping the movement of the capillary blood is one of the most prompt and effectual means of destroying the activity of the nerve-centres. Again, the danger to life from the action of chloroform arises from stopping (I do not say paralyzing) the heart, and while we know of a cardio-inhibitory centre in the medulla oblongata the excitement of which will slow, or stop the heart, we know of none whose excitement will increase its strength or arouse its activity. We must therefore look for some other explanation of the beneficial effects of the inverted position.

It appears to me that the strikingly good effect obtained by inverting the position of the body results from the direct excitation of the heart caused by the flow of blood into the right auricle (and ventricle), which takes place when the body is in that position.

The liver is roughly computed to contain one-fourth of the blood of the body. The length of the vena cava inferior, from the point where the hepatic veins open into it to its ending in the right auricle, is quite inconsiderable, and it is held open by its adherence to the comparatively unyielding substance of the liver. It is further kept patulous by its attachment to the tendon of the diaphragm just before empyting into the auricle. The hepatic veins, in their course through the liver to empty into the vena cava, cannot collapse, being adherent to the hepatic substance. All this is favorable to the pouring, so to speak, of the blood from the liver into the right auricle and ventricle when the body is inverted. We know from experiment that one of the most potent means of exciting the excised frog's heart to renewed activity, after it has ceased to beat, is to fill its chambers with blood or other fluids, and I do not see why the sudden distention of the auricle in the human body should not act in a similar manner.

Moreover, it is not impossible that a mechanical influence may contribute to the beneficial effects, inasmuch as the inversion of the body is brusquely made, and thus the sudden pressure of the heavy liver against the diaphragm and heart may act as a mechanical stimulant to the latter.

I have seen one case at least in which, during the inhalation of chloroform, death seemed imminent from stopping of the heart, and in which the organ was stimulated to contraction by pretty heavy blows administered with the open palm over the cardiac region. I see no reason why we should not use mechanical stimulation more energetically in case of stoppage of the heart during the administration of chloroform, even to the pricking of that organ with a needle through the wall of the thorax at the point where it is uncovered by the lung, with or without the transmission to it of the electric current. Of course, such procedures would be confined to desperate cases.

VISION PERMANENTLY AFFECTED BY SUNSTROKE.

By F. A. TUTTLE, M.D.,
JEFFERSON, O.

In a recent issue of The Medical Record, the question is asked: "Is vision ever permanently affected by sunstroke?" I answer yes, and will give a short history of my own case. In June, 1863, while in charge of a picket line as medical officer, I became insensible from sunstroke. The first thing I can recall after that was, I thought I had slept a long time, and wondered why daylight did not appear. I finally asked the attendants how long before daylight? They answered, it is just noon now. That was the first intimation I had that I was blind, and it was then the second day after the sunstroke. My hearing was intensely acute.

The first time that I saw light was on the third night. It was a lighted tallow candle in my tent, but I soon lost it and could not find it again that night. The next day seemed like pale moonlight. My sight gradually returned, but for two months I could not look at the bright sun without painful sensations. The angle of vision was entirely gone—it was like looking through two small gimlet-holes. The brightest day was mere twilight. I slowly gained my sight so that I could read coarse print, and now I can read for an hour (good print), although I can see but one word at a time. I have astigmatism that is corrected by lens. I have had to give up general practice, as on going from the out-door light into a room, it takes from fifteen to twenty minutes for my sight to adjust itself, and, of course, under those conditions, I cannot assume much dignity, for my feet seem to have a predilection for kicking over urinals and bed-pans. So I confine myself to my office practice, where the light is steady and strong. My vision now is fairly represented by looking through two tubes one inch in diameter. No angle of vision has ever returned. I am completely night-blind. Experts say that there is atrophy of retina. My general health has suffered much from the shock. As to blindness coming on ten or twenty years after sunstroke, I must agree with your correspondent in the belief that it is extremely improbable. There is no disease we meet, as members of examining boards, that gives us more trouble than profound shock to the nervous centres. Often the results are manifold. Objective symptoms may explain but little, and the subjective feelings and statements of the applicants still less.

I have taken much interest in this question, and, so far as my own experience and observation go, if a man received sunstroke in the army which did *not* affect his vision at the time or *shortly* after, and ten or twenty years later he loses his sight, I cannot see how to connect the last with his insolation.

This whole question of pensions, as it now stands, rests on the examining boards. Of course, the soldier's comrade remembers his straining his ankle on that march. It is patriotic that he should. The applicant comes before the board, and if he fails at first, he profits by experience. The next time he appears it is kidney disease. Examination shows an old cartilaginous stricture—perhaps the result of that furlough twenty years ago, from the Army of the Potomac, when he staid overnight in Washington—or chronic diarrhœa and its results. Who dare affirm that consumption, dyspepsia, piles, or all the ills flesh is heir to may not result from malnutrition of chronic diarrhœa? Verily, verily, if you wish to avoid perplexing questions, keep clear of examining boards. But, after all, the man who exposed his life in the army shall have the benefit of a doubt.

ADDITIONAL REPORT OF A CASE OF CHRONIC MEMBRANOUS ENTERITIS.

By H. S. KILBOURNE, M.D.,
U. S. ARMY, OF PORTLAND, ORE.

The general condition of this patient, whose case was reported in The Medical Record of February 18, 1888, during the summer and autumn of 1887, was much improved by a strict dietary and a course of Turkish baths. He gained twenty-five pounds in weight, and was well enough to resume his duties on February 13, 1888, but he still continued under observation. On March 4th he was found to have recurring attacks of nausea and vague sensations of discomfort in the abdomen, not amounting to pain. On March 9th, after a day of mental disturbance due to business matters, his nausea became so distressing and constant that he was ordered to take a drachm of mustard in a glass of warm water; this was taken, and produced free emesis, followed in a few minutes by a copious hemorrhage from the bowels (quantity estimated at about a pint). Frequent attacks of syncope followed the bleeding, and for several days exhaustion was so extreme that any attempt to rise in bed caused fainting. The patient was confined to his bed until May 1st, during which time he was slowly recovering. Emaciation and debility have been extreme. He is at this date (May 24, 1888) able to leave his bed during a part of the day, and his condition continues to improve.

Two peculiar features have been present in this attack: The hemorrhage (excited by the emetic), and a complete disappearance of the casts from the discharges from the time of the bleeding until the latter part of April, a period of about six weeks. Small flakes and strings of the casts have reappeared, and still continue to be found in the discharges, but not in all of them. During the attack the patient has presented most of the symptoms previously described.

The therapeutic record of the patient has been somewhat varied and extensive, as I have had some sixteen predecessors in the case. An attempt was made to arrest the discharge of casts by copious dilute injections of silver nitrate, administered once daily by the rectal tube passed as high as practicable, but without appreciable effect. A variety of other remedies have not proved of value. Iron, quinine, and calomel have in a general way been of service; malt liquors have been well borne; alcoholics were useful in steadying the heart after the bleeding, but later were not tolerated.

The chief reliance has been placed on a strict dietary of concentrated animal food in a liquid or semi-solid form, hot-air baths, massage, and faithful nursing.

NAPHTHOL IN STOMATITIS.

Dr. D. W. Loney, of Olena, O., writes: "I have used naphthol in several cases of stomatitis with good results. In a case of stomatitis in a nursing woman, which had resisted ordinary treatment for some time, the result was all that could be desired. In a case of mercurial stomatitis, with foul breath and secretions, naphthol gave almost immediate relief to many of the disagreeable symptoms. It is indicated in any case of stomatitis or sore throat where a reliable antiseptic and disinfectant is indicated; and has the advantage of being not unpleasant in taste, and non-poisonous in its effects upon the system. I have also used it in nasal catarrh with good results. It may be used for the mouth and throat as a wash or gargle, and in weak solution in the nasal spray or douche."

POST-PARTUM HEMORRHAGE AFTER DRINKING MULLED ALE.

Dr. F. W. Carmon, of this city, writes: "The following cases, occurring under my observation, may prove of interest by showing the influence of hot mulled ale in producing post-partum hemorrhage. Case I.—Mrs. C——, primipara, confined on October 19, 1887; labor normal, secundines came away naturally, and womb contracted well; patient did well in every way until the 30th; had sat up on the 28th, and, as she expressed it, felt as well as ever. On the 30th, shortly after dinner, during which she had drunk a glass of hot mulled ale, and while quietly sitting down, without any exciting cause whatever, she was seized with a terrific hemorrhage. I was away when sent for, and did not see the patient till two hours after the hemorrhage first occurred, and then found her in a state of collapse, with bloodless lips, sunken eyes, Cheyne-Stokes respiration, and pulse almost imperceptible. The patient had frequent fainting fits, and was still losing some blood. Under prompt treatment the hemorrhage was arrested, and a few hours later the womb was thoroughly curetted, but no particles of placenta or membranes were found. The patient ultimately made a good recovery. Case II.—Mrs. R——, multipara, confined February 28, 1888; normal and easy labor. On the seventh day after confinement she had a sudden and severe hemorrhage. Knowing the habits of the patient, I made inquiries as to whether she had been drinking or not, and found that she had drunk one or more glasses of hot mulled ale shortly before the hemorrhage occurred. Both of these patients were strong and healthy, and neither of hemorrhagic diathesis. In each case the hemorrhage occurred about one-half hour after drinking the hot ale, and, although I made careful inquiries, I was unable to find any other cause."

A SMALL SCARF-PIN SWALLOWED BY AN INFANT.

Mr. Washington Epps, of London, reports the following case: "Soon after Christmas Mrs. Scott's children were playing with the remains of some jewel cosaques, and the baby of eleven months took up a toy scarf-pin, put it into her mouth, and, before she could be prevented, swallowed it. The mother states she saw the pin disappear down her child's throat. This occurred at 3 P.M. Nothing was done to remove the pin. The child slept very well the whole night, and the following morning, eighteen hours after swallowing it, passed the pin, mixed with the fæces. The child had no pain whatever, and did not pass any blood. The exact measurements of the pin are: Flat head, composed of brass edge, with blue-glass jewel and tin-plate back, one-eighth of an inch in thickness and seven-sixteenths of an inch in diameter; pin very sharp, and loosely fastened to the head; one and one-third inch long."

Spontaneous Cure of Tubercular Pleurisy.—Dr. Fraentzel reports a case of acute pleurisy in the exudate of which, as well as in the sputum, large numbers of tubercle bacilli were found, which took on a favorable action and rapidly progressed to recovery.—*Charite Annalen*, 1887.

Progress of Medical Science.

Osteoplastic Amputation of the Thigh according to Gritti.—Dr. E. Ried, of Munich, discusses the value of Gritti's amputation, and attempts a finding of the proper indication for its application. Ten cases operated upon, according to the modification by the older Ried of Gritti's operation, in the Jena clinic, 1865–1884, are also reported. The originator of the operation intended to bring the cicatrix of the stump outside the point where it would be subjected to pressure, to shape the bottom of the stump of a tissue accustomed to pressure, and finally to eliminate the subsequent conicity of the stump after the healing processes were completed. The modification of Ried is as follows: The extremity is held in the extended position. The anterior flap is formed by an incision passing from the middle of the external condyle of the femur (on the right side), or the internal condyle (on the left) to within two or three finger-breadths below the border of the patella; the incision is carried from the other condyle downward and forward, meeting the first at the tuberosity of the tibia. The skin is retracted and the ligaments divided. The crucial ligaments are left intact. The femur is divided at the upper limit of the patella. The posterior flap is now formed of skin and connective tissue; the rest of the structure being divided as high as the situation of the point of division of the femur. The arteries were tied. The patella then is freed from fat and connective tissue, and the articular surface of the bone sawn off. The two flaps are apposed by means of one deep silver-wire suture and several superficial catgut and silk sutures; closing with drainage, antiseptic dressing, and higher position of the stump. The apposition of sawn surfaces of the patella and femur is a loose one. The quadriceps is given some room for shortening, without displacement of the patella. The exact apposition of patella and femur can be established after a few days, if the stump has been kept at perfect rest. In pre-antiseptic days the mortality resulting in cases operated upon by Gritti's method did not encourage its success. Antisepsis may change this entirely. On the battlefield this operation, even in the hands of a skilled surgeon, demands time, and the chances of displacement of the patella through transportation should be considered. The cases in which it is indicated are those where there is plenty of preservation of skin for the anterior flap. It is indicated where in ulcers of the foot the extensive changes in the skin bar out an amputation in the leg; in faulty union or imperfect healing of fracture of the leg in its upper third; in recent complicated fractures of the leg where there is no extensive laceration of tissues above the knee; in tumors of the upper third of the leg; in extended necrosis of the tibia which excludes amputation in the course of the leg; in gunshot wounds as high as the tuberosity of the tibia. It is excluded where the shot has involved in any way the knee-joint. The mortality in Ried's ten cases is thirty per cent. In one hundred and forty-four cases collected by Salzmann from all sources, the mortality reaches forty-eight per cent. In Ried's cases three were performed in pre-antiseptic days, with two deaths. Perfect cure and union of the patella resulted on an average in forty-eight days. (Salzmann, ninety-nine days.) As to age, Ried's cases ranged from the nineteenth to the sixty-sixth year of life.—*Annals of Surgery.*

Neuralgia of the Bladder.—According to Guyon, the causes of neuralgia of the bladder are varicocele, diseases of the testicle and kidneys, locomotor ataxia, and other forms of myelitis, hysteria, hypochondriasis, and nervousness. It is only to the last three causes that he pays attention, as the diagnosis otherwise is easy. The most common error is to confound neuralgia with painful cystitis. The following points are given: In cystitis there are frequent micturition, pain, and tenderness of bladder, and alteration of urine. In neuralgia the urine is normal, there is no frequency of micturition, the bladder is not tender on pressure over the hypogastrium, or through the rectum, nor on introduction of the sound. But there is a symptom which is present in all nervous people, or in those who are continually thinking of themselves—increased sensibility and resistance to the passage of an instrument through the membranous portion of the urethra, which is often mistaken for stricture. Further, the bladder will hold a considerable quantity of injected water, which it will not do in cystitis. Vesical neuralgia commonly occurs in people who suffer from similar pains elsewhere, and it is more frequent in men than in women. As regards treatment, its cause must be removed for a nervous person ; with no discoverable lesion, the general health must be looked after. Very gradual dilatation of urethra with bougies is recommended, but it is important that the dilatation be not rapid or forcible. Hydropathy is generally found beneficial.—*Le Progrès Medical.*

Spontaneous Rupture of the Rectum.—According to the Paris correspondent of the *Medical Press,* Dr. Quénu, at the Beaujon Hospital, related in detail the following case, which is not wanting in interest : A woman, aged sixty, of a very weak constitution, had suffered for the last six years from prolapsus of the rectum, which, however, she reduced with facility. Being habitually constipated, she made a free use of purgatives, and frequently passed blood. For the last six weeks she seemed to suffer more than usual, and kept her bed. The day of the accident she made great efforts in defecation, and suddenly she felt something come down, and great pain followed, with a considerable loss of blood. A doctor who was called in ordered her to be sent to the hospital, and when M. Quénu arrived he found the woman pale and cold, and on raising the chemise a portion of the intestine a yard in length was discovered, black and shrivelled. Introducing the finger into the rectum, a large rent by which the intestine had escaped was felt in the anterior wall. Under chloroform the abdominal wall was incised in the median line, and nothing but blood was discovered. The protruded intestine was removed close to the anus, but all attempts to suture the rent were useless. Iodoform dressing completed the operation. The patient succumbed on the following day. The autopsy revealed a rent of an inch and a half in length and a considerable amount of varicose veins, which M. Quénu considered pathogenic.

Sparteine as a Cardiac Tonic.—Sparteine is a base derived by Stenhouse from *spartinum scoparium,* and pronounced by Mills to be a tertiary diamine having the formula $C_{15}H_{26}N_2$. It is a colorless alkaline liquid, boiling at 287° C., of penetrating, disagreeable odor and very bitter taste. It is heavier than water, and only slightly soluble therein, easily soluble in ether or chloroform. It forms crystalline salts with acids, from which it is precipitated by alkalies. The sulphate is the best salt medicinally. Fick studied the action of sparteine on the animal organism, and Froumüller established its diuretic effect. Recently it has been rescued from oblivion by Germain Sée (*Comptes Rendus,* 1885, No. 21), who recommends it warmly as a cardiac tonic. This observer declared that sparteine had a stronger effect in prolonging systole and increasing the energy of the cardiac contractions than even digitalis or convallamarin ; also that rhythmic action was re-established, and that the pulse was rendered fuller and slower. A diuretic effect was not observed. Voigt (*Wiener med. Blätter,* 1886, Nos. 25-27) concluded that sparteine was a valuable drug, worthy to be placed beside digitalis, but that it had not the persistency of the latter in its effects, which, however, were superior to those of caffein, adonis vernalis, and convallamarin. Increased diuresis frequently resulted, but in this respect sparteine was easily exceeded by other medicines. Voigt recommended sparteine in insufficiency of the heart muscle, with or without valvular disease, in pericarditis, and as an adjunct to digitalis, or rather an occasional substitute. Leo (*Zeitschrift f. klin. Med.,* 1887, p. 143) found that sparteine acted as a powerful diuretic, and was beneficial in exactly those cases in which digitalis failed. The diuretic action Leo ascribes to direct irritation of the renal epithelium, and not to the increased blood-pressure from increased cardiac action. Palpitations and cardiac asthma were much relieved, but whether from some narcotic influence or from increased cardiac action is left undecided. The last observer in this department is Dr. Prior, Docent in the University of Bonn (*Berliner klin. Wochenschr.,* 1887, No. 36). According to Prior, sparteine only occasionally acts as a diuretic in health ; and this effect is probably due, when it occurs, to increased blood-pressure. He found it to act better in valvular failure than in simple insufficiency of the heart muscle from other causes. Its effects were, on the whole, fairly constant, rapid, and marked, but did not persist long. In some cases the heart's action was regulated for a long time by sparteine, the urine being increased, and œdema diminished or removed. Dyspnœa and palpitation were relieved within two hours, often less, in severe cases of heart disease, even when the heart's action was unaltered ; but the drug was of no use in bronchial asthma. A grain and a half of the sulphate was found the best to begin with. No cumulative action was made out. Prior advocates the use of sparteine sulphate in those cases in which digitalis has failed to do any good ; also when it is required to relieve severe stenocardiac attacks as speedily as possible, as sparteine often effects this even when the heart's action is unaltered by it. He also regards it as a valuable diuretic.—*The British Medical Journal.*

Pyridin as a Cardiac Excitant.—Dr. de Renzi has found pyridin to be an active cardiac excitant. He draws his conclusions regarding the action of the drug from seven cases which were observed at his clinic. 1. Pyridin, when given internally in daily doses of 6 to 10 drops taken in water, is well borne, and may be gradually increased to 25 drops, or even more. 2. The drug increases markedly the cardiac systole and lessens the feeling of oppression and fear. 3. The number of cardiac pulsations lessens, after the use of pyridin, simultaneously with the number of respirations. 4. By the use of pyridin the pressure of blood in the arteries is increased. After its use, by means of the sphygmomanometer, the arterial pressure was always found to be greater than before. 5. From numerous graphic tracings it was seen that the ascending line of the curve became much higher ; also that the pulsations became much more regular. In one case, which had been marked by an arhythmic pulse, pyridin caused this to entirely disappear, and the pulse became normal and perfectly regular. 6. Pyridin has conquered angina pectoris (?), as it relieves the attack more quickly and completely than any other remedy. In asystole it is also of great value, as it acts quicker than digitalis, and cumulative effects need not be apprehended.—*Therapeutic Gazette.*

Sterilized Dressings.—Two instructive papers have recently been published in Germany on this subject. In the May number of the *American Journal of the Medical Sciences,* for 1888, the following résumé of these publications is given : " Dr. Schlange has made a series of experiments which led him to the conclusion, first, that ordinary dressings thought to be aseptic are not so, but contain various species of germs ; and, next, that the antiseptic action of many, if not all of these dressings, believed to result from the liberation in the wound secretions of the material with which they are impregnated, is no less unreliable. The majority of his experiments were made with sublimate dressings and appeared to show that when freely mixed with blood or albuminous fluids much of the antiseptic action was lost. There are, of course, certain methods by which dressing materials can be rendered absolutely free from bacteria ; soaking in boiling water or in a sufficiently strong sublimate solution will effect this at once, and if we apply over a wound materials taken directly from boiling water or from the sublimate solution, and still wet, we may be sure we have put on a truly 'aseptic' dressing. The disadvantages of the wet dressings are numerous, however; among them being the interference with the evaporation of the wound secretions and the tendency to produce eczema, and they should be reserved for special cases.

"For routine employment we must depend on dry dressings. If, however, the wet sublimate gauze is taken, the layers separated from each other, hung up to dry, cut into the required sizes, rolled, etc., in every case infectious germs may be found afterward. For these reasons, in Von Bergmann's clinic, impregnation of the gauze with sublimate has been discarded and dependence is placed entirely upon gauze sterilized by steam. The raw material, cut of proper sizes and lengths, is put in a wire basket, exposed to superheated steam in an oven for an hour, then removed, and, after drying for a minute, the basket, with its untouched contents, is put in an iron cylinder from which the gauze is withdrawn as required. This secures, with the minimun of handling, an absolutely germ-free material under which wounds do admirably.

"Schlange thinks that the excellent results formerly ascribed to the antiseptic action of sublimate are really due to an entirely different cause—the speedy and undisturbed evaporation of the wound secretions. By another series of experiments he has shown that interference with the evaporation of these secretions and the development of germs are intimately associated, and that the latter disappear when the 'drying out' process is complete. While decomposition of the blood or discharges in a sterilized aseptic dressing is only possible through the action of germs alighting on its surface, it does not follow that such a dressing should be changed merely because the day after an operation the superficial layers become blood-stained. If, by attention to the patient's position, etc., evaporation is favored, no risk is ordinarily run. If, on the contrary, there is great soaking of the dressings the superficial layers should be changed, but the deeper layers, if they have begun to dry out, should be left undisturbed.

"E. Laplace examined a number of dressings containing two and a half, three, and four per cent. of sublimate, to determine whether or not they were aseptic. In 300 specimens of wood-wool only seven were not sterile, and all of 100 specimens of sublimate gauze were free from germs. He then investigated the antiseptic action of the same dressings, concluding that not only these but many others were unreliable, and that the good effects following their employment were largely due to the fact that they were aseptic when applied. His experiments showed that the germicidal action of the sublimate solution was satisfactory with non-albuminous fluids or discharges, but with albuminous fluids, like blood-serum, there was a precipitate of albuminate of mercury which left the solution inert. A mixture of equal parts of 1 : 1,000 sublimate solution and 5 : 1,000 solution of hydrochloric or tartaric acid prevented this result, and decomposing human blood, which was unaffected by the ordinary sublimate solutions, became absolutely sterile when treated with this mixture. He then tried it on a number of clinical cases with equally good results, arriving, finally, at the following conclusions: 1. We possess in the tartaric acid sublimate mixture a thoroughly satisfactory material for the disinfection of wounds. In order to obtain its good results, infected wounds must be washed daily for at least from ten to twenty minutes. In the treatment of fresh wounds a single washing and irrigation suffices. The solution for irrigation should consist of sublimate one part, tartaric acid five parts, distilled water 1,000 parts; for impregnating the gauze, sublimate five parts, tartaric acid twenty parts, distilled water 1,000 parts. 2. The sublimate dissolves more easily in the acid solution than in water, and the tartaric mixture remains incorporated with the dressings without destroying them. 3. Such dressings are thoroughly aseptic as well as antiseptic. 4. The dressing and the solutions are cheap and easily made and replaced."

Removal of a Hair-pin from the Peritoneum.—Dr. Freund, of Strasburg, has described a case where a hair-pin was found in the peritoneal cavity in the course of an exploratory operation for suspected disease of the uterine appendages. The patient was a sickly and emaciated woman, aged forty-one, who had symptoms of tertiary syphilis. Her menstrual period had been regular till about four months before she first applied for hospital relief; then it did not appear for two months; at the end of that period metrorrhagia set in, with the discharge of small shreds, and spasmodic pains in the sacral region and the hypogastrium. The discharge of blood continued for five weeks; then epileptiform fits occurred. The uterus was found anteverted, and a small oval tumor lay to its left side, connected by a tough cord with the pelvic wall. Tubal pregnancy was suspected. On March 2, 1887, an exploratory incision was made; the adhesions, which bled freely, had to be broken down, and a cyst of the left tube, "the size of an apple," was removed. It was universally adherent to surrounding structures; and, in securing some bleeding vessels to the great omentum, a piece of hair-pin, an inch long and consisting of part of the two shanks pressed close together just below their point of union, was discovered and extracted. A drainage-tube was left for twenty hours in the wound. The patient did well for a fortnight, then the stump of the tubal pedicle suppurated, and the pus which escaped contained ligature-threads. The first period after operation was attended with attacks of convulsions, which lasted eight days; but the second was only represented by the molimen without show, and by slight convulsive attacks. Ten days later a hard substance was detached, on vaginal examination, to the left of the cervix. The woman was in good health when last seen by Dr. Freund; but there were slight convulsions at every menstrual period. Should a portion of the hair-pin yet remain in the pelvis, the persistence of the neurosis is readily comprehensible; should the hard body be simply an inflammatory deposit, the persistence of the symptoms would be a feature already observed in other cases, where self-evident causes of nerve-irritation have been removed, the neurotic condition remaining for a long time after their removal. It appears that in this case the shanks of the hair-pin had been pressed together, and introduced into the uterus for the destruction of the imaginary fœtus, amenorrhœa having followed cohabitation. The pin had broken, found its way into the left tube, set up salpingitis, perforated the tube, and reached the omentum. Dr. Freund shows, on carefully considered evidence, that the prevalent theory that hair-pins are introduced into the genito-urinary tract, either in the belief that the practice may produce abortion, or for another repulsive purpose, is perfectly correct.—*British Medical Journal.*

The Treatment of Chronic Ulcers.—Dr. Bitot, writing in the *Journal de Médecine ae Bordeaux*, of March 18, 1888, speaks enthusiastically of the use of water-bags in the treatment of ulcers. He reports some cases of eczematous ulcers, which had resisted all modes of treatment, but healed readily under even pressure applied by means of small rubber bags partially filled with water.

Periodical Spinal Paralysis.—Greidenberg reported in *Vratch* the case of a soldier who suffered from total paralysis several times a month, each attack lasting one or two days. This condition, according to the man's report, had existed for ten years. The lower extremities were first attacked, the paralysis creeping up through the muscles of the trunk and upper extremities. The power returned in an inverse direction, the upper parts being the first to regain their normal strength. Westphal reported a somewhat similar case two or three years ago.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 16, 1888.

THE SELECTION OF CLIMATE FOR CASES OF PULMONARY PHTHISIS.

SEVERAL interesting contributions to the climatic treatment of phthisis have lately been made. As a rule, heretofore, an article on this subject meant simply the exploiting of some favorite health-resort by its local physician, or by some one who had been especially impressed with his experiences in one or two localities. But such mode of writing about climates is passing away before the larger knowledge and more critical spirit of the present day. It is questioned, now, if climate-cures will really be needed when home treatment has become more perfected. The late Dr. Austin Flint is reported to have said that one of the best climates for poor consumptives was the wards of Bellevue Hospital, and at the recent meeting of the Royal Medical and Surgical Society Drs. Quain and Pollock asserted that just as good results in phthisis could be obtained by home treatment as by that at health-resorts. The experiences of the Dettweiler Sanitarium bear out, in a measure, this latter view. Many patients have found out to their cost, as Dr. Robie states, that the Riviera has its mistral, the Alpine resorts their "föhn," or south wind, California its fogs, Florida its dampness and cold nights, and Colorado its storms of wind, dust, and sand.

Among the papers of interest which have appeared in the past year are one read by Dr. Assmann before the Berlin Medical Society; one by Dr. J. A. Lindsay, in *The Lancet;* one by Dr. Denison, read before the International Medical Congress (*Medical Register*); one by Dr. J. W. Robertson, on the climate of California (*Journal of the American Medical Association*); one by Dr. A. Tucker Wise, on the Alpine health-resorts; besides several special papers by Hössli on the Engadine, Schauffler on the climate of Texas, Geddings on the climate of Aiken, Lloyd on the climate of Asheville, Eyton Jones on the climate of Egypt, Frank F. Smith and Van Bibber on the climate of Florida, Douglas on the climate of Las Palmas in Grand Canary, Saville on the climate of Algiers, and F. Weber on the Crimea.

All these are referred to in order to show the number of alleged specially healthful spots which our favored globe offers to sufferers from pulmonary trouble. Besides this, Dr. Frederick I. Knight has written a careful article on "The Selection of a Climate for Patients with Pulmonary Tuberculosis" (*Boston Medical and Surgical Journal*, April 5, 1888).

Dr. C. Theodore Williams recently read an article on the treatment of phthisis at high altitudes, and Dr. Friedmann, of Berlin, has embodied observations, made upon himself and others, during a period of over seventeen years, under the title of "The Experiences of a Poitrinaire" (*Deut. med. Zeitung*, 1887).

Plainly, there are climates enough, and the important questions are, Whether the patient shall be sent away at all? and, if so, To what place shall he go?

As to these points, Denison thinks that the preferable altitudes range between 1,500 feet in the North in winter, and 10,000 feet in the South in summer. The contraindications for a high altitude are advanced age, heart disease, active pneumonia, high bodily temperature, extensive involvement of lung tissue, the stage of softening with marked pyrexia, or decided hemorrhagic diathesis.

Mountain-resorts, according to Dr. Lindsay, are most beneficial in cases of delayed recovery from pneumonia, chronic pleurisy with much fibroid change, incipient catarrh at the apex, chronic tubercular phthisis with good reaction, and hemorrhagic cases. In early uncomplicated cases with vigorous circulation, warm climates offer the best hope. When the circulation is feeble, or there is much nervous irritation, the choice lies between a sea-voyage and a dry inland climate like that of Upper Egypt, the interior plains of Australia, and southwestern parts of the United States.

Dr. Friedmann is of opinion (*British Medical Journal*) that the hygrometric condition of the air is of more importance than its density. As a rule, a fair proportion of moisture is beneficial, for though much moisture is somewhat depressing to the nervous system, it has a soothing effect upon the respiration. This question is equally made to turn upon that of the temperament, and most cases in the early stage of phthisis show the torpid "lymphatic" temperament, though this statement is contrary to the general opinion. Erethism, however, is a characteristic of all advanced cases, and of acute early cases. But different places vary considerably as to moisture in different seasons, and on this and other grounds (temperature, etc.) a change is occasionally desirable, especially in early summer. High plains and mountains are suitable for all torpid and chronic cases. Feverish cases do not bear a residence at the sea-side well.

Dr. J. C. Wilson thinks that patients with active febrile disturbance, those of highly excitable nervous organizations, and those who have repeated attacks of blood-spitting, should not be sent on sea-voyages.

Dr. Knight draws the following conclusions:

1st. As to patients presenting the earliest physical signs of chronic tuberculosis of the apex, who have as yet shown little, if any, general disturbance from the disease, and who complain only of morning cough and expectoration—these do best at mountain-resorts like those of Colorado and New Mexico.

2d. Patients with more advanced disease, showing some consolidation, but no excavation, nor any serious constitutional disturbance—these may do well at high altitudes; but it is better, if there is continuous hectic and considerable consolidation, to send them first to lower, dry elevations, like the pine-regions of Southern Georgia.

3d. Hemorrhagic cases—these do best at high altitudes.

4th. Cases of advanced disease with cavities or severe hectic symptoms. These should remain at home. But sometimes the moist, warm climate of Florida is beneficial.

5th. Acute cases should remain at home, at least till the acute symptoms subside.

6th. Cases of so-called fibroid or interstitial pneumonia. Special indications in these cases have to be considered. If the patient is young, and the heart is not enlarged, he may be sent to high elevations. If he is over fifty years of age, or if his heart is dilated, or if his cough is very harassing, a lower altitude should be chosen. Southern California offers excellent places for such, with varying elevation and moisture to suit individual symptoms.

7th. Patients recovering from acute pleurisy or pneumonia, in whom the irruption of tubercle is feared. High elevations is the place *par excellence* for these. The increased respiratory and consequent increased nutritive activity are exactly what is wanted to prevent the development of chronic disease.

8th. Patients in whom the tubercular process has seriously invaded the larynx. Such patients should be recommended mild, and even moist climates, and on no account be sent to high altitudes. Southern California answers the purpose well.

With regard to complications, it is admitted that cases with cardiac complications should not be sent to high altitudes. The same may be said of cases with acute or subacute rheumatic symptoms. Cases with nephritis or chronic rheumatism do not seem to be injured by high altitudes.

Dr. C. Theodore Williams, and Dr. H. Weber, found that among phthisical patients sent to mountain climates about forty per cent. recovered and about forty per cent. got better, and Dr. Pollock remarks that the forty per cent. which recover at high altitudes form just about the class of cases that recover in London.

Among the special conclusions which Dr. Williams draws as regards mountain climate are these :

1st. The circumferential chest-measurement augments from two to ten centimetres during the treatment. There is produced a considerable hypertrophy of the healthy pulmonary tissue, and more or less emphysema around the tuberculous lesions; the expansion of the thorax is accompanied by a diminution in the frequency of the pulse and of the respiration.

2d. Phthisical patients of both sexes equally profit by sojourn in elevated stations; as far as age is concerned, the results are less satisfactory in women before the twentieth year, and in men before the fortieth.

3d. The results are especially favorable in cases where there exists a hereditary predisposition.

4th. Mountain climates are useful in hemorrhagic phthisis, and diminish the tendency to hæmoptysis.

5th. The special influence of sojourn in elevated regions is observed at all altitudes above 1,500 metres.

6th. In the majority of cases the duration of this sojourn should be six months, at least.

7th. Mountain climates are useful not only in phthisis, but in other affections, such as incomplete development of the lungs and of the thorax, chronic bronchitis without bronchiectasis, pulmonary retraction after chronic pleurisy, spasmodic asthma not accompanied with notable emphysema, and in anæmia.

8th. Mountain climate is contraindicated in the following cases : (*a*) Tuberculosis with bilateral cavities, with or without fever ; (*b*) phthisis with considerable diminution of the respiratory surface ; (*c*) catarrhal phthisis ; (*d*) phthisis with considerable irritability of the nervous system ; (*e*) emphysema ; (*f*) chronic bronchitis with bronchiectasis ; (*g*) affections of the heart, of the large bloodvessels, or of the central nervous system ; (*h*) advanced age, or a state of feebleness too great to allow exercise in the open air.

PULMONARY RHEUMATISM.

Professor B. Ball has reported a case in which, during the course of acute rheumatism, general pulmonary congestion has occurred, with death following in a few moments. Sudden appearance of pulmonary consolidation in rheumatic fever is not very uncommon, and is especially frequent when pericarditis or pleurisy is present. In from seven to ten per cent. of cases of acute rheumatic fever some form of pulmonary or pleuritic trouble is noted.

Cases, however, in which the rheumatic phenomena leave the joints and appear in the lungs are not frequent, but do occur. M. Humblet has recently recorded such an observation in the *Archives Médicales Belges.* The patient, a butcher, aged twenty-six, a robust man, was attacked for the first time with acute articular rheumatism. Under treatment by salicylates all pain disappeared ; at the end of fourteen days he suddenly developed signs of pulmonary consolidation, with fever and "rusty" sputum. Under local treatment this disappeared at the end of five days, when rheumatic swelling with pain appeared in the left wrist. After twelve days the same symptoms appeared in the lung as before—dyspnœa, fever, etc. The joint affection disappeared, to reappear again in a few days. At the end of about a week both pulmonary and articular symptoms gradually began to disappear, and convalescence began.

There seems to be no doubt, in cases such as the foregoing, that the rheumatic poison produces an exudative inflammation in the lungs, with signs like those of pneumonia. The progress of the disease, however, indicates that it is not pulmonary rheumatism, as rheumatic pneumonia differs in its course from true croupous pneumonia.

SOCIETY PRACTICE AND ITS ABUSES.

Practising medicine, surgery, and obstetrics for benevolent societies has always been a poor kind of business. The doctor has been ill-paid, and we fancy that the patients have got, as a rule, but mediocre treatment, since many members resort to other practitioners when serious illness ensues. In this city, among certain German and Jewish societies, the emoluments are contemptibly small.

We learn with regret that this kind of practice is growing in other cities. The *New Orleans Medical and Surgical Journal* says : "The custom followed by so many physicians in this city, of taking 'society practice,' has grown to such an extent as to threaten destruction to all legitimate work by those few who value the dignity or well-being of the profession. Four-fifths of the people of this city are banded together into so-called 'Benevolent Associations,' whose objects are weekly indemnity while sick, free medical services, including drugs, and free burial in case of death. Every one of these societies annually chooses a physician, a druggist, and an undertaker, and always after fierce competition. Just before the annual election a committee goes around to some fifteen or twenty physicians, and the same number of druggists and undertakers, and requests each of these functionaries *to put in a bid.* Then begins the scramble. One physician will offer to do the work, which includes attention to the families of the members, for four dollers per member per annum; another will bid three, another two, and so on until, as actually happened a few weeks ago, the final and successful bidder sees a profit and honor in the job at 'forty cents per member per annum, payable quarterly.'"

The principle of society practice, and of provident associations generally, is a sound one, and cannot be attacked. But its application to medicine is made in a pernicious and evil way. The idea of getting "bids" for medical services, and accepting the lowest one, as if it were a contract to supply seamless socks or flannel underwear, is most shocking. It can only be great poverty or an utter want of self-respect that will allow physicians to enter into bargains in such a way. And it is extremely unwise for societies to contract at the lowest price for medical services upon which sometimes their lives may depend.

If a fair price for medical services were established by the societies, and then physicians were allowed to compete legitimately for the place, the system would not necessarily be a bad one.

THE TRUE SOURCE OF THE POWER OF THE PRESS

An American patent-medicine company recently sued an English company for damages, accusing the latter company of using the former's trade-marks. The American company sold a certain saint's "oil," and the English company advertised also a healing oil, substituting, we believe, St. Joseph for St. Jacob. The judge dismissed the motion promptly, with some severe and just words upon the matter of patent medicines.

The American company claimed that they had sold over twelve million bottles of their oil, and spent $2,000,000 in advertising it.

The English press, as a rule, were silent on the subject, but one journal, according to the *Chemist and Druggist*, said:

"To recur, however, to the sentence [of dismissal by the judge] we quoted in the beginning of this note—namely, that 'this American company which, according to its own statement, is flooding the English newspapers with advertisements of this quack medicine'—we may take this opportunity of reminding judges, journalists, and others whom it may concern, that to the patent-medicine advertisements of the past half-century they and all England owe, in a very large degree, and more, probably, than to any other influence, the wonderful development of the cheapness and consequent power of the press, which is one of the greatest features of the Victorian era."

"This," as Dr. Squibb, commenting on this matter, truly says, "seems equivalent to saying that it is good to foster quack medicines, although it may be at the expense of a legitimate materia medica, and of sound morality and truth and health, because quack medicines impose an enormous popular tax by which a powerful press is supported."

It is not the case, however, that our large city dailies are greatly supported by the quacks. The more reputable journals in this city will not average one or two columns as a daily subvention from quacks.

Local country journals and many religious papers, however, get their support largely from this class.

News of the Week.

The American Laryngological Association holds its Tenth Annual Meeting at Washington, D. C., September 18, 19, and 20, 1888. The following preliminary programme is announced: "Ten Years of Laryngology," Rufus P. Lincoln, M.D., New York; "Congenital Bony Occlusion of the Posterior Nares," Charles H. Knight, M.D., New York; "The Effects of varying Rates of Stimulation on the Action of the Recurrent Laryngeal Nerve," Franklin H. Hooper, M.D., Boston; "Subglottic Laryngeal Enchondroma," E. Fletcher Ingals, M.D., Chicago; "A Photographic Study of the Laryngeal Image during the Formation of the Registers, and Production of Variations in the Pitch of the Singing Voice," Thomas R. French, M.D., Brooklyn; "Lupus of the Nose, Pharynx, and Larynx," Samuel Johnston, M.D., Baltimore; "Imaginary Lingual Ulceration," George M. Lefferts, M.D., New York; "A Possible Substitute for Tracheotomy and Intubation in certain Cases," Edgar Holden, M.D., Newark; "Antiseptic Nasal Surgery," Clarence C. Rice, M.D., New York; "A Case of Sarcoma of the Tonsil," Alexander W. MacCoy, M.D., Philadelphia; "A Case of Subglottic Chronic Stenosis of the Larynx cured by Dilatation," Frank Donaldson, M.D., Baltimore; "Internal Œsophagotomy," John O. Roe, M.D., Rochester; "The Treatment of Atrophic Rhinitis by the Galvanic Current," J. H. Hartman, M.D. Baltimore; "The Anatomy of the Nasal Chambers," Harrison Allen, M.D., Philadelphia; "Notes on a Case of Nasal Caries, complicated with Meningitis; successfully treated by means of the Surgical Drill," William C. Jarvis, M.D., New York; "On Fixation of one or both Vocal Bands in the Phonatory Position (so-called Abductor Paralysis)," F. Donaldson, Jr., M.D., Baltimore; "Residence at certain High Altitudes as a Means of Cure for Laryngeal Phthisis," Clinton Wagner, M.D., New York; "Further Investigations as to the Existence of a Cortical Motor Centre for the Human Larynx," D. Bryson Delavan, M.D., New York.

The Medical Department of the University of Pennsylvania is to have a Maternity Hospital consisting of a central building and two wings.

A Christian Physician.—The Union League Club resolutions on the death of Dr. Agnew, prepared by Chauncey M. Depew, and presented by Sigourney W. Fay, contain the following: "If all Christians were like Dr. Agnew all men would become Christians. With him religion was not a cloak, but a career. It was not a formula, but a faith. It was not alone a liturgy or a creed, but the practice during every working hour of the commandment, 'Thou shalt love thy neighbor as thyself.' The profession was not only enriched by his genius and science, but thousands of young men owe to him the opportunities and examples which will enable them to take up his work and follow in his steps. The loss of such a man in the prime of life and usefulness is a public calamity, only mitigated by his good works while living and his glorious memory after death."

Engravings of the Late Dr. Agnew.—At the last meeting of the Ophthalmological and Otological Section of the New York Academy of Medicine a committee was appointed for the purpose of arranging for the making and publication of engravings of the late Dr. Agnew. We are informed that members of the profession who desire such an engraving, accompanied by an autograph signature, should send their names and addresses to the Secretary of the Committee, Dr. Charles H. May, 640 Madison Avenue, New York City, at once. When all such names shall have been recorded, those who have requested a copy of the engraving will be notified of the cost of the same, either by the publisher or by the committee having the matter in charge.

Ovariotomy in the Aged.—Dr. Schröder operated successfully on a patient aged seventy-nine, and on one aged eighty; Dr. Miner operated on a woman aged eighty-two, and recently Dr. Homans, of Boston, operated successfully on a patient aged eighty-two years and four months.—*British Medical and Surgical Journal.*

Of Executing the Death Sentence by Electricity, Dr. B. W. Richardson says: "Euthanasia for the worst of criminals, by the side of so-called natural, but often most cruel, death for the rest of mankind, is practically the proposition; a proposition which carries with it its own condemnation."

A Colored Medical Society.—The Lone Star Medical Association is an association of the colored physicians of Texas. Its second annual meeting was held at Austin, on May 14th and 15th. There is a society of young doctors in this town. The members are not colored, but they sometimes paint things red.

The Marshall Hall Prize is awarded only once in five years, and so far only three men have received it. These are Dr. Hughlings Jackson, Dr. Ferrier, and recently Dr. W. H. Gaskell.

"Are Doctors Scientists?" was a question Judge Turner had to settle. Mr. Goodjer, of Newcastle, objected to a charge for "preparing scientific evidence" made by Drs. D. H. Watson and Hughes. He held that this was professional and not scientific evidence, and therefore was only entitled to the usual professional fee. The judge, however, held that doctors must also be regarded as scientists, and allowed the item.—*Medical Standard.*

Massage Establishments in Chicago.—The police recently raided a massage establishment for being disreputable. Massage shops, as the police call them, are becoming assignation houses.—*Medical Standard.*

The Hydrobromate of Quinine is a good form for hypodermic use.

The Wholesale Price of Cocaine is now about two or three cents per grain.

The Defects of American Quarantine.—"Dr. Walcott, in his address on State Medicine," says the *Medical Standard,* "paid a well-deserved tribute to the now moribund National Board of Health, whose excellent system of inspection made it a terror to mercenary steamship companies and inefficient quarantine officials. These elements, however, finally gained the upper hand, and, aided by a New York homœopathic politician whose feeble and corrupt administration has since led to his removal from office, and by the old-code head of the unconstitutional Marine Hospital Service, who desired to make sanitation a pretext to continue an unconstitutional tax for the benefit of a special class of workingmen no more entitled to special medical treatment by the Government than any other workers, succeeded in preventing any appropriation for the Board by Congress, with the result, during the present year, of spreading small-pox broadcast over the country. The Association's endorsement of the Bureau of Health bill was a deserved rebuke to the Marine Hospital Service clique. To this desirable result Dr. Walcott in no small degree contributed."

Quack Advertisements in Religious Newspapers.—At the Centennial General Assembly of the Presbyterian Church, lately held in Philadelphia, the Committee on Bills and Overtures recommended the adoption of a resolution that the General Assembly, while disclaiming responsibility for, or authority over, religious journals not published under its direction, disapproves of "all those advertisements of patent medicine, dishonest in form, fraudulent in substance, or prejudicial to the refinement, modesty, and purity of the home life."

A Library for the Kansas State Medical Society.—Mrs. Jane Stormont, widow of the late Dr. J. W. Stormont, of Topeka, Kans., has offered the State Medical Society $5,000 to found a permanent library at Topeka.

A Simple Remedy for the Benefit of the American Medical Association.—The *Medical Standard* asks but little. "If," it says, "the American Medical Association will cast off the Washington barnacles which infest it, rid itself of the incubus of the national specialist organization already mentioned, retire the old fogies and young snobs who have been prominent in its councils of late years, and expel all diploma-mill professors, its republican organization will have a full chance to demonstrate its infinite superiority over any other body."

Dr. Harmon Heed, of Windsor Locks, Conn., died on April 7, 1888, in the forty-eighth year of his age.

Suppressing Quackery.—The Orange County Medical Society, at its annual meeting at Middletown, June 1st, adopted a resolution instructing the censors to prosecute illegal practitioners.

A National Association of Railway Surgeons.—Railway surgeons seem to think that they have special and peculiar interests in calling for a special national organization. At any rate, a committee of railway surgeons, consisting of Drs. C. B. Stemen, J. H. Tresset, and R. L. Sweeny, have called a meeting at the Palmer House, Chicago, Ill., on June 28th, at 9.30 A.M.

To Allay the Thirst of Diabetics, Dr. Duchenne recommends potas. phosphat., ʒ j.; aquæ, ℥ v. M. ʒ ij. to ʒ iv. several times daily.

The Association of American Institutions for Idiotic and Feeble-minded Persons holds its twelfth annual session at Toronto, Canada, June 18th. A number of interesting papers are on the programme.

A very Good Way to give Iodine is, says Dr. Squibb, by inhaling fifteen to twenty drops of iodide of ethyl. Iodine is found in the urine within fifteen minutes after fifteen to eighteen inhalations. It is indicated in syphilis, and in various disorders of the circulatory and respiratory apparatus. The bottle containing this iodide should be kept tightly corked in a dark place.

Six Living Children at a Birth.—According to the *Bund* of May 10th, at the village of Castagnola, near Lugano, Switzerland, the wife of the local Communal President, aged thirty-eight, has been recently delivered, at full term, of six living children, every one of which, however, died in the course of a few hours after their birth. This startling event has induced a correspondent of the *Berner Volkszeitung* of May 19th, p. 2, to publish the following statement, which, he says, can be very easily verified: "Many years ago a woman, residing at the village of Fullenbach, near Olten, was safely delivered of seven living, though tiny, infants. Since the nearest church at the time was at Olten, the seven children had to be carried to that town to be baptized. It happened that one of the rustic godfathers somehow lost one of his future godchildren on the way, the accident being discovered only after the napkins and wrappings had been carefully examined at the church. The happy father of the seven, plunged now into the very depths of unhappiness, registered a solemn vow to the Holy Mother that if 'the lost child was found alive he would erect on the self-same spot a chapel dedicated to her holy name.' The infant was soon found safe and sound, lying at the left bank of the river Aar, about five hundred steps from the Aarburg Bridge, close to Ruttigen, where there now stands the chapel as erected by the father, true to his solemn promise. An official document, relating in detail all these obstetrical and other events, is said to be exhibited within the chapel for public edification.—*British Medical Journal.*

Reviews and Notices of Books.

Practical Microscopy. A Course of Normal Histology for Students and Practitioners of Medicine. By Maurice N. Miller, M.D., Director of the Department of Normal Histology in the Loomis Laboratory, University of the City of New York. Pp. 217. New York: William Wood & Co. 1887.

This little volume is designed to pave the way for those who wish to study histology in a thorough manner. It is not intended to supersede the use of the larger manuals on this branch of anatomy. The subject is arranged by Dr. Miller in an eminently practical way, the language is clear and concise, the illustrations are well executed, and, altogether, the work commends itself to the attention of students and beginners in histology and microscopy.

A Manual of Auscultation and Percussion. By Austin Flint, M.D., LL.D. Fourth edition. 8vo, pp. 280. Philadelphia: Lea Brothers & Co. 1885.

The original work done by the late Dr. Flint in the development of the art of physical diagnosis will always make this manual an authority on the subject. Among all the works issued on this topic during the last few years none exceeds this one in simplicity and completeness. The fact that it has passed through four editions attests its popularity. There is a tendency among physical diagnosticians to make altogether too many varieties of morbid chest sounds, and especially of râles. The conciseness of Dr. Flint's manual is one of its chief advantages.

Hysteria and Brain Tumor. By Mary Putnam-Jacobi, M.D. 8vo, pp. 216. New York: G. P. Putnam's Sons. 1888.

This is a reproduction of various essays on nervous diseases, which have been read before societies or contributed to current literature. They are all of remarkable interest, and marked by that cogent reasoning which characterizes Dr. Jacobi's writings. The first two, from which the title is derived, occupy considerably more than half the volume, and are its most noteworthy contents.

Die Morphiumsucht und Ihre Behandlung. Von Dr. Albrecht Erlenmeyer. Dritte vermehrte und verbesserte Auflage, mit 22 in den Text gedruckten Holzschnitten. Berlin: C. Heuser's Verlag. 1887. The Morphine Habit and its Treatment. By Dr. Albrecht Erlenmeyer. Pp. 463.

This is a large and systematic treatise on morphine mania, and fills a vacancy in medical literature. The author has seen much of the disease, and his contributions to its symptomatology and cause are especially interesting. The book is a little diffuse, and would bear condensation, when it would be quite worth an English translation.

Du Catarrhe Chronique, Hypertrophique et Atrophique des Fosses Nasales; de l'Ozène, Obstruction catarrhale des Trompes d'Eustache, Végétations adénoïdes du Pharynx. Traitement par la Galvano-caustique chimique. Par Dr. Garrigou-Desarènes. Pp. 238. Paris: Adrien Delahaye et Emile Lecrosnier, Editeurs. 1888.

The author of the present treatise has got a galvano-cautery and treats his nasal cases with it. He is so pleased with the results that he writes a book. Other books, no worse than this, on similar subjects have been written when some other therapeutical fad was the inspiring influence.

Dr. Garrigou-Desarènes has written an interesting and suggestive work, containing many points of practical interest. He is not perhaps to be blamed because his treatise is not a learned, well-balanced, or philosophical one.

Neurectasy; or, Nerve-stretching for the Relief or Cure of Pain, being the Bradshaw Lecture, delivered at the Royal College of Surgeons of England. By John Marshall, F.R.S., LL.D. With an Appendix by the Author, and 12 illustrations by Victor A. H. Horsney, F.R.S. Pp. 53. London: Smith, Elder & Co.

These lectures, delivered in 1883, have been brought down to date by an appendix, and the work furnishes a very satisfactory, though not perfectly complete, *résumé* of the present status of nerve-stretching.

The Practice of Medicine and Surgery Applied to the Diseases and Accidents Incident to Women. By W. H. Byford, A.M., M.D., Professor of Gynecology in Rush Medical College, and of Obstetrics in the Woman's Medical College, and Henry T. Byford, M.D., Surgeon to the Woman's Hospital of Chicago. Fourth edition. Philadelphia: P. Blakiston, Son & Co. 1888.

Byford's treatise on women has been reviewed in our pages several times. The new edition differs in no essential respect from former issues. Revision, correction, and amplification have made the fourth edition more valuable than its predecessors. The fact remains, however, that this work represents Byford's teachings more faithfully than American gynecology. It is a book to be consulted by the specialist, rather than the student or general practitioner.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN OBSTETRICS AND GYNECOLOGY.

Stated Meeting, April 26, 1888.

J. E. Janvrin, M.D., Chairman.

Dr. James B. Hunter read a paper (see p. 653) entitled

UNUSUAL CASES OF PELVIC CELLULITIS AND THEIR TREATMENT.

Dr. A. P. Dudley opened the discussion with the history of two cases of pelvic abscess of more than usual interest. In the first case the patient had lifted a heavy weight, following which a tumor developed rapidly on the right side. He saw her about three weeks afterward, when she was suffering considerable fever, chills, and pain, and was very weak. She had what seemed to be a simple cyst in the right side. He had her taken to a hospital, where he attempted to relieve her without operating. It was difficult to determine whether she had a simple cyst, a pelvic abscess, or some other pelvic condition. That there was cellulitis was not doubted, but the pelvic walls were so tense that fluctuation could not be elicited through the vagina. Palpation over the abdomen pointed to what was believed to be a simple cyst. After as long a delay as he thought was justifiable, he opened the abdomen, and found on the right side a small cyst of the broad ligament. He tapped the cyst, but still thinking there must be some other condition present in the pelvic cavity, he did not excise the sac, but passed his hand in and felt a convex instead of a concave surface, which he attributed to some accumulation below, although fluctuation was still absent on account of the very tense condition of the tissues. He passed a trocar through the pedicle of the cyst into the tissues below, and there escaped over a pint of very fetid pus. The pelvic abscess was independent of the peritoneal cavity. He washed it thoroughly, and drained by a tube passing out through the cyst and abdominal walls. The patient recovered.

The second case was that of a woman who fell downstairs, struck the right side, and very shortly there developed fever, tenderness, and a thickening of tissues on the right side, felt per vaginam. The thickened condition or tumor soon extended around to the left side. As pointing was rather to the left side, a trocar was introduced, and about half a pint of pus was withdrawn. The patient got better; but there remained some thickening on the right side, between the bladder and uterus. His consultant thought it should be approached through the abdomen, but he concluded to use the aspirator, which he did, experiencing some difficulty in avoiding the uterine artery, and there escaped a pint of clear, limpid fluid. It came from a parovarian cyst. The patient was then convalescent.

Dr. Dudley believed the majority ot pelvic abscesses arose from a diseased condition of the ovaries and tubes; but he was convinced that they might occur entirely independent of the peritoneum. In the latter class of cases he believed aspiration was a safe method of treatment. Where the peritoneum was implicated there should be a free incision.

Dr. H. J. Boldt had been especially interested in the case of the author in which the intestine was adherent to the abscess. He had had two similar cases. In one laparotomy was done, and the bladder was found spread out upon the abscess and adherent. The case was let alone, yet the patient recovered. In another case, somewhat similar to the first one related by Dr. Dudley, he stitched the wall of the abscess to the abdomen, and drained. The patient recovered. He thought that after the diagnosis had been made, and it was intended to operate, the intention should be carried out before the patient had got too far along in a septic condition.

Dr. H. T. Hanks would emphasize the importance of Dr. Hunter's injunction to be careful in diagnosis, and, unless it could be made with certainty, to proceed with any operative interference with great caution. He could not forget his first case, which caused him much anxiety; but Dr. Walker, the consultant, advised him to wait, and, quieted his fears with the statement that it would not rupture into the peritoneal cavity. Finally rupture occurred into the vagina, and the patient recovered. Dr. Hanks thought that by early judicious treatment, as by frequent vaginal and rectal injections of hot water, the use of counter-irritants over the lower portion of the abdomen, antipyretics, and rest in bed, we ought to avoid the formation of large abscesses, and the necessity for an operation in many cases. When an operation was determined on, a free incision should be made, and pockets of pus be broken up. He was in the habit of making the opening into the abscess-cavity by means of a cervical dilator which had been brought to a sharp point, so that it would readily enter the tissues, and then the handles could be separated, enlarging the opening by dilatation.

Dr. Buckmaster thought an instrument would prove very satisfactory in these cases which he had seen employed by Dr. Thomas, consisting essentially of an aspirator-needle with a corkscrew-like projection, which entered the tissues and yet was sufficiently blunt to push aside any arteries. It left a track which would very readily close, differing in that respect from the one left by a straight-pointed instrument.

Dr. J. B. Hunter said the instrument employed by Dr. Hanks for penetrating the abscess-cavity was much like one devised a few years ago by a doctor of San Francisco.

A NEW SUTURE-FASTENER FOR SILVER WIRE, ESPECIALLY ADAPTED TO OPERATIONS ON THE CERVIX AND PERINEUM.

Dr. A. H. Goelet presented a new fastener for silver-wire suture, which was intended especially to do away with the necessity for twisting the ends. The need of such a fastener was seen in the fact that the silver-wire suture, when twisted, often left an indentation in the tissues which remained for years. By cutting the tissues it caused suppuration and interfered with ready union. To avoid this he had devised a lead button shield, which was pushed down over the wires when these had been put in place and clamped like the shot-fastener. The button could be made of various sizes, had a smooth concave under-surface, with rounded edges, while the upper surface had a teat-like projection upon the middle, through an opening in which the wire passed, and when in place it was clamped and thus held in position. Two sutures fastened in this manner on either side of the lacerated cervix were sufficient to hold the edges together. It was claimed that the expanse of lead covering the edges of the wound a little distance from the suture tended to retain those edges in apposition. The same objections to the use of the silver wire obtained in operations upon the perineum and abdominal wound in laparotomy, as in lacerations of the cervix, and could be overcome by the use of the suture-fastener presented, but modified somewhat to adapt it to the new situation.

Dr. Hanks would try the suture-fastener on the cervix, and would expect to derive benefit from it. In operations upon the perineum he used silk.

Dr. Cleveland thought the invention an ingenious one, but he agreed with Dr. Hanks, that those who had had much experience with the operation and had learned to do it skilfully and carefully would find little use for it. He found little difficulty from the silver wire in the cervix when it was not twisted too tightly. If there was likely to be difficulty, he cut the sutures on the fifth day without removing them, and thus took off the strain. On the perineum he used catgut, except the first suture, which was of silver wire.

Dr. James B. Hunter thought that if the silver-wire sutures were not twisted too tightly they would not cut, and if they were drawn too tightly no device would prevent them from cutting. It was at the point where they entered, and not where they were twisted, that the cutting would then take place. He thought the twist also had the advantage of leaving the suture in a shape that it could be tightened or loosened if found necessary. He remarked that some years ago Dr. Thomas devised a clamp through which the wires passed, and its surface extended somewhat over the wound, but he had abandoned it.

Dr. A. S. Hunter expressed the view, which several others present also entertained, that the button described could not have any effect in holding a larger extent of the wound-surface together than the suture would do alone. He also thought there would be danger of cutting both ends of the wire beneath the button when it came to removing it, and in that event it would be difficult to find the piece buried in the tissues.

Dr. Jacobus thought the kind of suture had less to do with bad union than failure to properly cut out the diseased tissues. Cut out the lacerated portion as it should be done, and union would readily take place under any form of suture.

Dr. Goelet closed the discussion, and claimed that the concave surface of the button did retain the edges of the wound in position a distance from the suture.

NORTHWESTERN MEDICAL AND SURGICAL SOCIETY OF NEW YORK.

Stated Meeting, April 18, 1888.

R. C. M. Page, M.D., President, in the Chair.

Dr. Burchard read the paper of the evening (see p. 655),

THE TREATMENT OF STRICTURE OF THE URETHRA BY ELECTROLYSIS.

Dr. Robert Newman had been gratified by the clear statement given of the subject. He would state that, in the two lists referred to, he had included only patients who had persisted in the treatment. He had not included cases in which treatment had been discontinued in the middle of the course. All of the cases included had, however, been followed, and it was known that relapse had not occurred. Failure was, he thought, always due either to wrong management of the current or to badly made or badly selected instruments. On having his battery renewed he had received it back presumably all right, and, on using it, he had been able to pass the stricture, but had been unable to withdraw the instrument. He had heard of others who had had this difficulty, and had known of cases in which the physician had then forcibly withdrawn the instrument. In a cited case he had suffered the patient to lie quietly for a few minutes, when the instrument had been spontaneously released. Afterward he had discovered that the connections of his battery had been changed, so that he had inadvertently used the negative pole. One must be certain of having the positive pole. In testing the poles, it was to be remembered that the needle of the galvanoscope turns to the positive pole. When placed in water, bubbles of hydrogen rise from the negative pole; when placed in a solution of potassium iodide, iodine gathers as a brown coloring at the positive pole.

It had been said that the speaker failed to cure because he dilated only to a 25 or 28, while it was the practice to cut to 40. It should be remembered that his instruments were blunt-pointed, while those ordinarily used were conical. The result obtained with his 28 was equal to that of the 34 of others.

A rule often neglected was, never to use the current when the urethra was inflamed, when there was an acute discharge, or hemorrhage showing a denuded surface. The cases in which the treatment was painful were, as a rule, cases in which this rule was neglected.

It would surprise many to know how widely the method had been accepted outside of New York. At the recent meeting of the American Medical Association, the West had risen as one man in its favor. Dr. Marsh's criticism but revealed his ignorance in regard to electrolytic action. The speaker recalled a case in which the patient had been cut seven times, and the contraction was so great that it was impossible to introduce even a guide. A country-practitioner had subsequently cured the patient by this method.

Dr. Burchard inquired whether a discharge was common during the first twenty-four or forty-eight hours after treatment. In his experience with three or four cases in which there had been no previous discharge, it had been quite profuse for several days.

Dr. Newman replied that such a discharge was not infrequent during the first two days; also, it was not uncommon for the coagulated mucus to form a plug which dammed back the gases produced and interfered with urination. The patient first found himself unable to urinate, but was relieved by the discharge of the plug, which came away with a puff like that which followed the cork of a soda-water bottle.

Dr. Burchard asked whether Dr. Newman checked this discharge.

Dr. Newman replied that he did not. He did not tamper with the urethra in any way during the first three or four days.

Dr. Burchard asked whether Dr. Newman's cases were troubled with irritability of the bladder after the treatment.

Dr. Newman replied that there was no such tendency, unless the current was too strong.

Dr. Burchard asked what was the usual duration of the séance.

Dr. Newman replied that he simply passed the instrument through the stricture, and withdrew it. From two to ten minutes were required, five minutes being the average. Where the instrument was kept in too long, no doubt irritation would result. He referred to a set of tunnelled-L sounds, by means of which he was able to withdraw the urine after the operation, so that the passage of an additional instrument was not required.

Dr. McLaury referred to an article by Sir Henry Thompson, of London, in which the alarming dangers of the old method were graphically represented.

Dr. Powell had had no personal experience in electrolysis of the urethra. In a patient said to have been discharged by Dr. Newman as cured, he had, subsequently, done the median operation for close stricture. He could not vouch for the veracity of the patient, who might have been one of the incomplete cases to which Dr. Newman had referred. The speaker would like to ask Dr. Newman two questions: First, what tissue was involved in the majority of strictures—the mucous membrane, or the submucous tissue; second, whether the mucous membrane was destroyed by the current, or whether a perfectly sound tissue was left?

Dr. Cole begged to take exception to Dr. Newman's remark in regard to the size of a bougie. A 28 was a 28, whether its extremity was conical or not; a 34 was a 34.

Dr. Wood was pleased with the favorable consideration given to this subject after the years of criticism, amounting to vituperation, which had been heaped upon it, especially in this city. Regarding the question of cauterization, he recalled a former meeting held in his own house, where Dr. Newman had demonstrated the effect of the current, using cartilage covered with mucous membrane. The cartilage had been dissolved and returned to its original elements, while the mucous membrane had been uninjured. He recalled a case which he had referred to Dr. Newman for treatment. The patient was fifty years of age, the bladder was emptied by drops, and a filiform bougie was entered with difficulty. The patient had suffered with chills, and had been disqualified for business for several months. After eight weeks' treatment he had been entirely cured, and had had no difficulty since. The speaker had recently referred the question of recurrence to Drs. Bangs and McBurney at the St. Luke's Hospital. He had asked whether, after division of stricture at one point, there was permanent cure. They had replied that the sound must be passed occasionally for a year, or even during life in some cases. The permanency of the cure by electrolysis was thus in its favor. Electrolysis destroyed the whole of the ring, while internal urethrotomy destroyed it in but one place.

Dr. **Dessau** referred to a case—that of a young man, twenty-two or twenty-three years of age, with two strictures, one two and one-half inches and one three inches back. Dilatation had been practised for a number of months without progress, and he had determined to resort to electrolysis. He had provided himself with the electrodes furnished by the Galvano-Faradic Co., and a new battery using five cells. At the end of five minutes there had been no pain, and the stricture had not been passed; at the end of ten minutes the stricture had not been passed, and bubbles of gas were escaping from the meatus; at the end of fifteen minutes he had turned off the current, there still being no pain and no progress. He had then been unable to remove the instrument for a number of minutes. It was not improbable that the wrong pole had been used. While there had been no pain throughout the treatment, the next day the prepuce had become œdematous, the whole organ had been swollen, the stream of urine erratic, and there had been a sanious discharge. Strange to say, one stricture had been cured, although the technique of the operation had been a failure. The other stricture had been subsequently divulsed.

Dr. **Baruch** had had no personal experience with the method, but referred to a report by Dr. Samson, of Texas, who had had a number of successful cases.

Dr. **Page** had recently tried the method upon one case. The stricture had dilated pretty well, but the application had caused such burning pain that the patient would not submit to it again. The patient's discharge had just ceased and the urethra was still tender; possibly, too, the negative pole had been used. He would not be deterred from trying it again in another case. The subject was timely. Urethrotomy had been abused. The speaker did not favor urethrotomy. Where cutting was done, a scar resulted and the stricture was apt to come back. The majority of strictures could be cured by dilatation.

In the absence of Dr. Burchard, Dr. **Newman** closed the discussion. The 200 cases he had reported had remained well for from three and a half to eleven years. He knew of no other method with which this could be compared.

In regard to Dr. Powell's question, he would say that the stricture might involve both the mucous and the submucous tissue, but that it might also involve the latter alone. So well accepted was this fact that some surgeons, in performing external urethrotomy, divided only the external tissues and left the mucous membrane entire. To the second question, he would say that the influence of the current was felt within a radius of one to one and one-fourth inch. It was capable of causing the absorption of the stricture without injury to the mucous membrane, if the current was sufficiently weak. Irritation was produced if the current was too strong or too long-continued, but the patient recovered from this in the course of two or three days. He had never seen the mucous membrane destroyed by the treatment.

In regard to Dr. Cole's objection, he would say that a conical bougie would forcibly dilate, and hence retraction would follow. The blunt bougie would, on the contrary, fail to enter at all until the stricture had been destroyed, and retraction did not follow its use. He had spoken with this sense in view when he had said that his 28 was equal to a 34. The electrode used by Dr. Dessau had been badly insulated, probably, and the current had escaped not only at the end of the instrument but along the stem also.

In judging of the strength of the current he had formerly trusted to his sensations, using more cells as the fluid became weak. He now used the galvanometer. Measured by the galvanometer, the strength varied between three and five milliampères.

Dr. **Powell** then presented an

URETHRAL DILATOR

devised by himself. It was his custom neither to electrolyze nor to cut, but to rely upon dilatation in the treatment of stricture. With the aid of cocaine it was possible to dilate to the full size of the urethra without pain, and he could refer to cases in which from three to ten years had gone by without a relapse.

Dr. **Leo** had used dilatation for eighteen years. It was the most ready method, and in his cases had always given good results.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Thirty-ninth Annual Session, held in Philadelphia, June 5, 6, and 7, 1888.

Tuesday, June 5th—First Day.

The Society was called to order by the President, Dr. **R. J. Levis**.

After prayer by Rt. Rev. Bishop Whitaker, Dr. **John H. Packard** delivered the Address of Welcome.

Some amendments relating to membership in the County Societies, and to the appointment of a Committee on Pharmacy, proposed at the last meeting, were adopted.

Dr. **Traill Green**, of Easton, delivered the

ADDRESS IN HYGIENE.

After speaking of the necessity of ventilation, bathing, and cleanliness, the author alluded to the fear of suffering in the hour of death, and considered it to be unfounded. Even in pseudo-membranous croup death is, as a rule, unaccompanied by suffering. Reference was also made to the fear of premature burial, which is quite general. A careful study of reported cases, however, showed that there is no well-authenticated case in which this has happened. In regard to the dread of being eaten by worms after burial, experience shows that there is no foundation for it.

Dr. **Edward R. Mayer**, of Wilkesbarre, then delivered the annual

ADDRESS IN MEDICINE.

The speaker dwelt largely on the value of internal antisepsis, referring especially to the use of the sulphites. He had found that after their administration in families where cases of scarlatina, diphtheria, measles, and pertussis existed, new cases rarely appeared. He had also found these agents of service in the treatment of these diseases. The use of antiseptic agents has largely taken the place of astringents and opium in the treatment of diarrhœal affections. The use of calomel in the beginning of gastro-intestinal affections was recommended. Afterward sulphuric acid, the sulphites, salicylates, etc., come into play.

Dr. **William Pepper**, of Philadelphia, presented a paper entitled

A CONTRIBUTION TO THE CLINICAL STUDY OF ALBUMINURIA.

He requested that the paper be read by title and referred to the Publication Committee. In doing so, he stated that the paper was based on the records of the chemical study of the urine in the cases occurring in his private practice during the past eight months. The examinations had been made by Dr. J. P. Crozier Griffith. The total number of cases was 239. Of this number, albumin was absent in 96 cases. The number in which albumin was found continuously or at some period was 143. As a rule, the test employed was that of Heller. It is therefore evident, he said, that there must be some forms of albuminuria not significant of organic disease of the kidneys. In 80 of the cases in which albumin was found, its presence was explained by the presence of pus or blood. In many cases, however, it was difficult to decide that the quantity of blood, pus, or other accidental addition to the urine was sufficient to explain the amount of albumin found. In 41 cases the presence of albumin could not be explained in this way, but yet, in none of these could casts be found, although they were looked for with great care. In only 22 cases of the 143 were casts found.

Dr. Frank Woodbury, of Philadelphia, read a paper on the

EFFERVESCENT FORM FOR THE ADMINISTRATION OF CERTAIN REMEDIES.

Attention was called to the fact that the last Pharmacopœia contained only two preparations intended to be administered in effervescent form. These are: Liquor magnesii citratis and magnesii citratis granulatus. Sparkling wines and malt liquors owe most of their palatability to the excess of acid which they contain. Modern works on therapeutics say very little with reference to the action of carbonic-acid gas as a medicinal agent; yet it plays as important a part in the animal as in the vegetable economy. Effervescing preparations were much employed by practitioners of a generation ago, and they afford a valuable means of administering nauseous and disagreeable medicines. Small quantities of alcohol are much more stimulating when given in the effervescent form than in the shape of spirits. Malt liquor is, when properly given, a better hypnotic than bromide of potassium. It is useful in gastralgia or nausea and in renal colic. It has been found useful, also, as a food and stimulant in children suffering with diphtheria. Effervescing draughts are especially valuable in fevers, being grateful to the patient, and tending to reduce the temperature and favor the action of the skin. In local affections of the digestive tract these agents are commonly resorted to, and in true migraine they may be given with the addition of a small quantity of deodorized tincture of opium. The author concluded the paper with the hope that the next Committee on Revision of the Pharmacopœia might be induced to extend the list of granular effervescent salts, and, if possible, establish uniform and standard formulæ for the carbonated and other mineral waters, both natural and artificial, that are now so largely used by the profession and the public.

Wednesday, June 6th—Second Day.

Dr. R. J. Levis delivered the President's address, entitled

THE TRADITIONAL ERRORS OF SURGERY.

Reference was made to the traditional custom of medical schools of recommending foreign medical works in preference to domestic books. The imperfect study of practical anatomy was regretted. With regard to specialism, it was said that the greatest advances in modern medicine have been made through attention to special lines of study and practice, but no specialty can flourish which separates itself from the common sources of science. Very few great advances have been made in medicine without being subjected to the opposition of prejudice. No more striking instance of this is to be found than that shown by the opposition to, and long probationary trial of, ovariotomy. The tardy recognition of the value of antiseptic surgery is a discredit to the times. It is now nearly thirty years since this method was introduced by Lister.

The traditional tendency to complication of surgical instruments and apparatus was alluded to. Few instruments are made straight, if it is possible to complicate them by making them crooked. Among other errors, largely the result of tradition, are the delay in operative interference in depressed fractures of the skull, the delay in operating in cases of strangulated hernia, and the failure to recognize the distinctly local origin of certain malignant growths, and the fact that they may be eradicated by thorough operation.

Dr. John R. Packard presented a communication on the proposed

STATE BOARD OF MEDICAL EXAMINERS,

in which he criticised some of the provisions of the bill which had been recommended by the Society.

Dr. L. F. Flick, of Philadelphia, read a paper on

THE CONTAGIOUSNESS OF PHTHISIS,

in which he took the ground that the evidence in favor of the contagiousness of this affection was sufficient to establish it as a fact.

THE ELECTION OF OFFICERS

was then held, with the following result: *President:* J. B. Murdock, of Allegheny; *Vice-Presidents:* L. H. Taylor, of Luzerne, Benjamin Lee, of Philadelphia, W. W. Dale, of Cumberland, W. S. Rowland, of York; *Permanent Secretary:* William B. Atkinson, of Philadelphia; *Recording Secretary:* Charles W. Dulles, of Philadelphia; *Corresponding Secretary:* J. H. Musser, of Philadelphia; *Treasurer:* O. H. Allis, of Philadelphia, officers for ensuing year.

It was voted to hold the next meeting in Pittsburg, beginning on the third Tuesday in May, 1889.

Dr. Theophilus Parvin, of Philadelphia, then read the

ADDRESS IN OBSTETRICS.

A large portion of the paper was devoted to a consideration of the advance made in the use of electricity in obstetrics and diseases of women. A consideration of the treatment of placenta prævia followed, the speaker holding that before viability the rule should be non-interference, unless there was severe hemorrhage. After viability, the occurrence of bleeding is the indication for immediate operation.

In closing the address, an earnest protest was entered against the indiscriminate performance of operations for the removal of the ovaries.

Drs. J. Price and **Penrose**, of Philadelphia, repeated the experiments showing the use of

INJECTION OF HYDROGEN GAS

in the diagnosis of perforation of the bowel in wounds of the abdomen, as performed by Dr. N. Senn at the recent meeting of the American Medical Association.

Dr. M. Price reported a successful case of

REMOVAL OF THE KIDNEY

for pistol-shot wound, and exhibited the patient, who was a girl, aged fourteen.

Dr. John B. Deaver, of Philadelphia, read a paper on

NEPHRECTOMY FOR MORBID GROWTHS.

He reported an unsuccessful case of removal of the kidney for carcinoma. The following were the author's conclusions: 1. Sarcoma in children should not be subjected to operation; 2. Sarcoma in adults should be operated on; 3. Carcinoma in adults, unless seen in an early stage, does not justify an operation; 4. Malignant morbid growths, in the majority of cases, should be removed by abdominal section; 5. Benign growths of the kidney are best treated by lumbar operation. If too large to be removed entire, they should be removed in sections, the pedicle being first ligated.

Dr. S. T. Davis, of Lancaster, reported a successful case of

REMOVAL OF THE UTERINE APPENDAGES.

Dr. J. H. Musser, of Philadelphia, read a memoir on the

LIFE AND CHARACTER OF BENJAMIN RUSH.

Dr. William F. Waugh, of Philadelphia, read a paper entitled

THE SPECIFIC TREATMENT OF TYPHOID FEVER.

The author had used the sulpho-carbolate of zinc, in a number of cases, with such results as to warrant a further trial of the drug.

Thursday, June 7th—Third Day.

Dr. H. C. Wood, of Philadelphia, delivered the

ADDRESS IN MENTAL DISORDERS.

The medico-legal aspect of this subject was the chief point discussed, and the manner of trying criminal cases in which the question of insanity arises was severely criticised. The defects existing in the Pennsylvania law on this subject were pointed out, and a resolution for the appointment of a committee to consider the advisability of making changes in it was offered.

Dr. James McCann, of Pittsburg, followed, with the annual

ADDRESS IN SURGERY,

taking for his subject the surgery of the brain.

Dr. J. V. Shoemaker read a paper on

THE CAUSE AND TREATMENT OF PSORIASIS,

exhibiting two patients.

Dr. B. Alexander Randall, of Philadelphia, delivered the

ADDRESS IN OTOLOGY.

This was followed by several papers on allied topics.

Dr. J. William White then exhibited two patients on whom the

RADICAL OPERATION FOR HERNIA

had been performed.

Dr. Charles W. Dulles, of Philadelphia, made a report on

HYDROPHOBIA,

giving the results of his study in this subject during the past year.

Dr. Goodwillie, of New York, read by invitation a paper describing new methods of treatment of

HARE-LIP AND CLEFT PALATE.

Dr. Laurence Turnbull reported a case of

EAR DISEASE,

in which the whole of the labyrinth was discharged from one ear, the result of disease following diphtheria and scarlet fever.

The Society then adjourned.

The Presternal Muscle.—At a meeting of the Anatomical Society of Paris, M. Roubanovitch reported an instance of this rare anomaly in man. Before the patient's death it was noticed that there was a prominent longitudinal band on the right side of the sternum. This was visible only during inspiration. At the autopsy a small fusiform muscle was found extending from the anterior surface of the manubrium to the seventh costal cartilage. The tendon of insertion was divided into three fasciculi, attached respectively to the fifth, sixth, and seventh costal cartilages. The tendon of origin was much smaller than that of insertion. One of the fasciculi of the latter was united with one of the points of the insertion of the pectoralis major, a fact which explained the prominence of the muscle during inspiration, the two muscles contracting simultaneously.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE CONFLICT AT THE COLLEGE OF SURGEONS—COLLEGE DIPLOMAS—THE NEW WORK-ROOMS AT THE COLLEGE—SUTURE OF RUPTURED BLADDER—COCAINE IN ACUTE TONSILLITIS—RHEUMATIC PARALYSIS OF VOCAL CORDS—THE QUEEN'S JUBILEE HOSPITAL IN THE LAW COURTS AGAIN.

London, May 19, 1888.

Those who advocate reform at the College of Surgeons have received a somewhat disheartening check, not to say repulse. It is now some months since the Council of the College applied for a Supplementary Charter. The members and fellows took the opportunity to lay their claims before the Privy Council, and not only was a petition with several thousand names forwarded to that body, but two deputations, of fellows and members respectively, attended before the Lord President of the Privy Council to state the grievances and urge the claims of the members and fellows. The latter were hopeful that some notice would have been taken of their statements, and that possibly their request to be represented by counsel before the Privy Council might have been acceded to. It is now announced that the Privy Council will grant the Supplementary Charter asked for by the College Council, omitting certain points "upon which there has been a controversy with the fellows and the members of the college." Almost the only alterations made by the new charter (thus modified) will therefore be the enlargement of the powers of the Council of the College as regards the amount of property they may hold, and the privilege now to be granted to the fellows of voting at the elections to the council by means of voting-papers in place of having to attend personally. Should the Supplementary Charter be granted without further question, the latter innovation is one that may be trusted to effect considerable changes in time. The Members of Council will no longer be the nominees of a few metropolitan surgeons, but will be representative of the whole body of fellows distributed throughout the country. The constituency made up of the fellows of the College of Surgeons is far more scattered than that of the fellows, or even the members, of the College of Physicians. By far the majority of medical men practising as pure physicians are living in London and the more important of the provincial towns and cities. The same might be said of those practising as pure surgeons, but the fellowship of the College of Surgeons is possessed by many medical men in general practice, and therefore located in all parts of the kingdom. Its possessor is not bound to restrict his practice to surgery, and all that the diploma implies is that certain stringent examinations have been passed. On the other hand, both the fellowship and membership of the College of Physicians imply that any one holding either practises solely as a physician. The license of the College of Physicians and the membership of the College of Surgeons are the inferior diplomas, which are merely licenses to practise, and correspond one with the other. Indeed, since what is called the "conjoint scheme" has been in operation, they are only given together, after the double examinations have been passed.

The recent extension of the college buildings has included the erection of work-rooms for scientific research. It is now announced that these are to be granted for the use of members and fellows on certain conditions. In all applications sent in it will be necessary to describe the proposed investigation and give a complete list of the material and apparatus required. The expenses of the investigation will be defrayed by the college, but a record must be kept of the time daily spent in work, and the place and mode of publication of the results will be determined by the Council of the College, to whom, also, investigators will be required to make reports on the progress made from time to time. The new work-rooms are likely to be extensively used, for the institutions in London at which scientific research can be carried on under favorable conditions are not very numerous. The Brown Institution is one, and work can also be done under certain conditions in the laboratories of University and King's Colleges. Hitherto, however, these have been the only institutions at which could be found the appliances necessary for conducting original researches in advanced physiology and pathology.

At the Clinical Society's last meeting Mr. Symonds read notes of a case in which he had sutured the rent in a case of rupture of the bladder in a female child, aged seven. The injury was caused by falling from a height. The abdomen was opened, about twenty Lembert's sutures inserted to close the rent in the bladder, and the peritoneum washed out with weak carbolic lotion and bichloride of mercury solution. The abdominal wound was then closed and a catheter tied into the bladder. The child did well for a time, but died on the eighth day. A collection of pus was found on the left side of the bladder, extending into the left ilio-lumbar region. The peritoneal part of the wound was soundly healed, but the non-peritoneal part was gaping widely, the sutures having torn through. The urine had escaped and set up the suppuration. Dr. De Havilland Hall then read notes of three cases of acute parenchymatous tonsillitis treated by cocaine. He applied the cocaine in solution (twenty per cent.) to the fauces by means of a brush. In one case the patient was somewhat strongly affected by it. Dr. Hall pointed out that the drug lessened sensibility and also the blood-supply; hence it facilitated deglutition. Dr. Percy Kidd then read notes of a case of complete bilateral paralysis of the vocal cords following acute laryngitis. He considered the paralysis to be rheumatic in origin. Recovery took place. Dr. Semon observed that it was the first case on record of bilateral rheumatic paralysis. Mr. Nunn then described a case of necrosis of the greater cornu of the hyoid bone and of ossified portions of the thyroid cartilage. The patient was thirty-three years of age. He had served in India for a short time, and suffered from constitutional syphilis. An abscess formed from which sequestra were discharged. Three attacks of profuse hemorrhage took place. Pneumonia followed, and finally phthisis, from which the patient died.

The Queen's Jubilee Hospital has again figured in the law courts recently. I should imagine the promoters of the hospital begin to wish they had never had anything to do with it. The superior landlord has, jointly with the occupiers of the adjoining premises, brought an action against the sub-lessee of the hospital premises to prevent the use of the latter as a hospital, on the ground that such use came within the scope of the prohibition in the lease which forbade the carrying on of any noxious trade. It was further argued that persons suffering from unpleasant complaints visited the hospital, and that there was no need for the latter, the neighborhood being a high-class one without any poor, those who visited the hospital coming from a distance. Judgment was given for the plaintiffs, but leave to appeal was granted.

CAMPHORATED CARBOLIC ACID.—In the *Correspondenzblatt für Schweizer Aerzte*, No. 7, 1888, p. 229, Dr. Th. Schneider, of Basle, recommends camphorated carbolic acid as an "elegant, reliable, and very convenient antiseptic preparation." As is well known, when one part of crystallized carbolic acid and three parts of powdered camphor are shaken up together in a test-tube, a colorless limpid fluid is produced. This mixture does not possess either the characteristic odor or the rubefacient and caustic properties of carbolic acid, while the antiseptic power of the latter remains intact. When placed on the tongue the compound causes but a very slight burning sensation. It has no effect on polished steel.

Navy News.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 9, 1888.

MAGRUDER, A. F., Surgeon. Detached from the Yantic, and granted sick leave.

BATES, N. L., Medical Inspector. Ordered to the Richmond.

KIDDER, B. F., Medical Inspector. Detached from the Richmond, and wait orders.

HEYL, T. C., Surgeon. Ordered to the Receiving Ship St. Louis.

STREETS, T. H., Surgeon. From St. Louis and to Medical Examining Board, as Recorder.

DUBROSE, R., Past Assistant Surgeon. From Naval Hospital, Norfolk, and to the Jamestown.

WELLS, HOWARD, Past Assistant Surgeon. From the Jamestown, and to U. S. Hospital, Chelsea.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 9, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	4	2
Scarlet fever	169	31
Cerebro-spinal meningitis	1	1
Measles	223	17
Diphtheria	136	44
Small-pox	13	2
Yellow fever	0	0
Cholera	0	0

CORRESPONDING MEMBERS OF THE PARIS ACADEMY OF MEDICINE.—At a meeting of the Paris Academy of Medicine in March last, among the names of foreign physicians proposed for corresponding membership were those of Drs. L. A. Sayre and W. T. Lush, of this city.

INHALATIONS OF CARBONIC ACID are recommended by Dr. E. Weill (*La France Médicale*, March 8, 1888) for the treatment of certain forms of dyspnœa, especially when occurring in phthisical patients suffering from laryngeal trouble. He attributes the good effects observed in such cases to the anæsthetic action of the gas upon the respiratory mucous membrane.

A NEW STETHOSCOPE, devised by Dr. Reynal-O'Connor, is described in *Le Progrès Médical* of April 14, 1888. The tube is of metal, and has three ovoid enlargements, which serve as resonators. The ear-piece is joined to the cylindrical part by a joint, so that the head of the auscultator need not follow all the movements of the stethoscope. Inside the cylinder are packed a red and blue pencil, an æsthesiometer, and a tape-measure.

THE ITALIAN SOCIETY OF HYDROLOGY AND CLIMATOLOGY will hold its first annual meeting in Bologna, in October next. The object of the Society is to make the Italian physicians better acquainted with the mineral springs of Italy.

THE MEDICO-LEGAL IMPORTANCE OF THE HYMEN.—Dr. E. S. Wikee writes, in the *American Practitioner*: "The presence of the hymen may be disguised by the presence of prolapsus vaginæ. I think the tendency of modern writers is to lay too little stress on the presence or absence of the hymen. There are, of course, many ways other than moral by which the hymen may be removed, but instances are rare; they are very rare. From the opinions expressed by most writers one would think they had been so unfortunate as never to find a hymen; therefore all women are unvirtuous. Like the young man who has spent his substance with harlots, he thinks all women are harlots; or, to cover his own sins, pretends that virtue is unknown save in new-born babes. In some localities and among some people this state of affairs may exist, but in the majority of places it is happily not true. Duverney says: 'When not found, in nine hundred and ninety-nine cases out of one thousand defloration has taken place.' He regards the restoration of the hymen as one of the many fables.' Casper says: 'I must declare that when a forensic physician finds a hymen still preserved, even its edges not being torn, and along with it (in young persons) a virgin condition of the breasts and external genitals, he is gratified in giving a positive opinion as to the existence of virginity, and *vice versa*.'"

Castration and the Development of the Genital Tract.—Dr. Kehrer has made a series of experiments to ascertain the effect of castration on the development of the genitals in young animals. He castrated rabbits between two and three months of age, and killed them one year later. He found that unilateral castration or spaying caused no arrest of development. On the other hand, when the operation was performed on both sides, the genitals and mammary glands remained stationary, never developing beyond the stage which they had attained when the essential organs were removed. Dr. Kehrer attempted to prove which theory was true—Pflüger's, according to which there existed in the uncastrated female a stimulus to growth through periodical irritation of the ovarian nerves set up by the ripening of follicles which goes on long before puberty; or, on the other hand, the theory that spaying caused a disturbance of the blood-supply of the remaining genital organs, through the occlusion of the ovarian arteries. For this purpose he ligatured the ovary and ovarian artery in two series of experiments. He found that neither in unilateral nor in bilateral ligature of the tubes or extremities of the uterine cornua, with separation of the ovarian arteries, was the normal development of the genitals in any way affected. He concluded that the ovarian nerves, or some other and unknown influence in connection with the ovaries, played the most prominent part in stimulating the development of the genital tract.—*British Medical Journal*.

The Influence of Cardiac Disease on the Mind.—In this year's Gouldstonian Lectures, delivered by Dr. J. Mickle (*British Medical Journal*), on "Insanity in Relation to Cardiac and Aortic Disease and Phthisis," the author speaks as follows concerning the influence of affections of the heart on the mind: "The chief factors of the brain circulation being the heart's action, the vasomotor apparatus of brain, the molecular functional activity of brain, and the atmospheric pressure (opposing return from skull, whose contents are partially withdrawn from its influence), it is evident that cardiac disease may play an important part in modifying that blood-supply and the cerebral functions. And the shrewd forecast of the late Sir G. Burrows, as to its frequent connection with insanity, has been justified by actual observation. Speaking of the mental disease with which so frequently an accentuation of the aortic sound is allied, Professor Rudolf Arndt said that it often takes origin when degeneration of the heart has followed its overstrain, and here the mental disorder, grounded in a disposition of the affected individual, is to be taken as an expression of general disease rather than as a brain disease, strictly speaking. The influence of heart diseases in the production of brain affections is chiefly to bring about functional disorders of the brain, including insanity. Although Dr. R. Law and Dr. William Stokes held that, independently of arterial disease, which Rostan connected with white softening of the brain, the latter might be brought about by heart disease, yet I have never seen a case of such 'exsanguineous softening' fairly attributable to cerebral anæmia the effect of cardiac disease; for in all cases where disease of the vessels locally was insufficient to account for the circumscribed softening, I have found embolism, or hemorrhage, exudation, or new-growth. But whatever their connection with cardiac or other disease, these several forms of local gross cerebral lesion may originate mental derangement, chiefly with dementia. An examination of this department of the relations of cardiac to mental disease would occupy too much time, does not fall within the scope of these lectures, and will now be dismissed for good. How, then, may cardiac disease either modify the symptoms of preexistent insanity, or of that which appears about simultaneously with itself; or give origin to the mental disease, play the part of a chief factor of the psychical malady? A question of difficulty and complexity. Combined as they usually are in operation, the several elements may be disentangled in some examples. They are as follows: 1. The heart disease may act by disturbing the balance of the general circulation in various ways and degrees. 2. Similarly, it may act by disordering the intra-cranial circulation (this includes its effect on the local vaso-motor mechanisms). 3. It may operate by leading to a change in the composition of the blood within the cranium; or, 4, of the blood generally. 5. It may act by the pulmonary disorder it induces, and the morbid impressions and sensations resulting therefrom, so that eventually some of the effects arising are of pulmonary origin, or partly so. 6. Through the nerves it may become a source of peripheral irritation, and influence cerebral functions reflexly, by sympathy, inhibiting some forms of activity, deranging others. Lest the above statements should bear a dogmatic impress, I must add that as yet they are not actually demonstrated and generally accepted facts. Some, indeed, while admitting a change of balance of general or of local association in heart disease, changed blood-pressure within the vessels, and altered quality of the blood therein, yet deny any effect, worth mention, of these on the production of mental symptoms, and hold that the original endowment of the nervous system, and the previous mental qualities, govern the state of psychic functions during the existence of heart or renal disease, of changes of pressure and circulation. Nevertheless, as regards the first two of the above-mentioned results of cardiac disease, and factors of mental, the preceding discussion shows their importance in determining the state of the brain, and therefore in producing disorders of it. In relation to this come cases with feeble circulation and with cerebral vessels imperfectly filled, in which the mental state or the sensory brain functions varied with the oscillations of arterial anæmia of the brain, according as the subject was in the erect or horizontal position; as where one, feeble-minded, apathetic, and peevish while in the erect position, became intelligent, lively, and conversational in the recumbent."

After some further explanatory remarks of a similar kind, the author continues as follows:

"With disabling heart disease, and especially if thereupon pulmonary disease supervenes as a secondary result, or even independently, come a general disturbance of the balance of the circulation, and impeded return of blood to the right side of the heart, including impeded return of blood from the cranial cavity, and all the more so as here comes into play the closed nature of the skull. And not only is the venous blood in the sinuses and large cerebral and meningeal veins brought to a state tending to stagnation, but it also acts backward toward, and upon, the arteries, in this course giving rise to irregular circulation, local retention and blood-stasis, poisoning of the parts with retained effete products of tissue-metabolism, and to changes in the pressure of the blood upon the vascular walls, and in the tension of the brain. Lung disease greatly enhances this condition of the intra-cranial circulation, a condition which also is accompanied with arterial cerebral anæmia, which we have seen the aforementioned changes tend to produce. And this being the state of affairs, should there now be also histological changes in the walls of the cerebral blood-vessels, their partial occlusion starves the brain substance, their diminished elasticity further aggravates the stasis and promotes gravitation of blood. Of the evil effects of persistent passive congestion of the membranes and brain substance, I need not tarry to speak. Yet the heart disease, in some forms particularly, and eventually in all, of itself directly, often mechanically, occasions a defective arterial supply to the brain, with or without venous congestion, and in the train of this arterial anæmia (and venous congestion) follow all the changes in the circulation and nutrition of the brain to which I have referred. And utterly mistaken are those who, in the diseased or healthy state of the brain-vessels, respectively, would seek the complete solution of the seeming mystery that one case of heart disease is attended by mental symptoms, and one, apparently similar, is free therefrom."

THE MICROBE OF YELLOW FEVER.—It is not often that the lay press publishes precise and reliable information concerning strictly medical topics. A noteworthy exception is found in a recent issue of the *New York Times*, which speaks editorially on the subject of the alleged microbe of yellow fever. The following account is given of this subject:

"The report of Dr. Sternburg concerning his search for the microbe of yellow fever will surprise many who have been led by apparently trustworthy statistics and descriptions to believe that the microbe not only had been discovered, but also had been used for the successful inoculation of thousands in Brazil and Mexico. It was proposed two or three years ago that the reported discoveries of Dr. Freire and Dr. Carmona, and the methods of inoculation used by these physicians, should be investigated by a commission of three persons appointed by the President The commission bill did not become a law, but provision was made in an appropriation bill for such an inquiry as had been proposed, and the man selected to do the work was Dr. George M. Sternberg, who had for some years been engaged in a study of yellow fever and in microscopic researches like those by which the Southern doctors were said to have found the microbe, and to have perfected their methods of inoculation.

"The brief account of his investigation which has been published in *Science*, and in which it is stated that he could not find the micro-organism described by Drs. Freire and Carmona, serves to recall the reports by which public attention has been directed in the last four or five years to the work of these physicians. Dr. Domingos Freire, of Rio Janeiro, began his researches in 1880, and in 1883 he inoculated human beings with the culture of the microbe which he believed he had found. He was aided by the Brazilian Government. He declared that the microbes were present in great numbers not only in the blood and organs of yellow fever victims but also in the soil of cemeteries where such victims had been buried. For the cultivation of them he chose the method of Koch, attenuating the virus by the successive inoculation of a number of guinea-pigs or rabbits. These animals died of a disease which seemed to be yellow fever. Human beings inoculated with the attenuated virus suffered a very slight attack of the fever, the symptoms continuing for two or three days. In a letter to Dr. Gaston, of Atlanta, Ga., dated December 29, 1885, and published by the House Committee on Epidemic Diseases, Dr. Freire said:

"'I judge that the commission of medical men of which you spoke will come very soon to give us the distinguished honor of verifying the results of our prophylactic mission, which up to the present time has been attended with such notable success that not one of the six thousand who were inoculated during the current year has died of yellow fever, while nearly five hundred who were not inoculated have sunk into the grave as victims of that disease.'

"Six months later, in a letter to Dr. Holt, President of the Louisiana Board of Health, Dr. Freire said:

"'I have performed over 7,000 inoculations with full success. The immunity was almost absolute, notwithstanding the intensity of the epidemic this year. More than 3,000 persons who were not inoculated died of yellow fever, while among the 7,000 inoculated, inhabiting the same infected localities, subject to the same morbid conditions, but seven or eight individuals whose disease was diagnosed as yellow fever died.'

"Writing to Dr. Watson, Secretary of the New Hampshire Board of Health, he declared that in the districts where 3,051 had been inoculated, 166 of those treated lived in houses in each of which from one to five fatal cases occurred, and in all of which 278 uninoculated persons died. One year ago statistics relating to Dr. Freire's work were laid before the Academy of Sciences in Paris by Drs. Gibier and Rebourgon, who are said to have repeated in that city his experiments, and these statistics were to the effect that 6,524 persons had been inoculated in Rio Janeiro in 1885 and 1886; that in those years the total number of deaths from yellow fever was 1,675, and that among these victims there were only eight who had been inoculated.

"It does not appear that the methods of Dr. Freire were reproduced in Mexico by Dr. Carmona. The latter is said to have begun his investigations ten or twelve years ago, and to have carried them on independently. He inoculated himself in September, 1881, and in the following five years is said to have inoculated 1,250 persons. In an account published in 1886 it was stated that of the first 208 not one was attacked, and that of the next 532 there were 26 who had the disease. Ten employés in the Mazatlan Custom House were exposed, and the four who had been inoculated escaped, while the fever killed their six companions who had not been inoculated. There is a marked difference between Carmona's methods and theories and those of Freire.

"These are some of the statements which convinced many American physicians and Congress that the reported discoveries ought to become the subject of an official inquiry. It seems to have been generally admitted that Dr. Sternberg was well fitted for the work of investigation. He has not completed that work, but neither in Rio Janeiro nor Vera Cruz has he found microbes. Neither the micrococci of Freire nor the zoöspores and yellow peronospores of Carmona have become visible under his microscope. But he has learned that, out of 44 inoculated persons in Rio, 22 took the disease and 9 died—the death-rate in this group exceeding the usual rate. What becomes of those stories about the failure of inoculation in only 8 cases out of 6,524? It may be that Dr. Sternberg will yet find some confirmation of the theories of Freire or those of Carmona, but his failure thus far to do so is not encouraging to those who would rejoice if it could be proved that a sure defence against yellow fever had been discovered."

TAR WATER IN HEMORRHAGE.—Dr. Corneille de Saint-Marc finds that distilled tar water has a hæmostatic effect very similar to that of hamamelis. When prepared with the tar of pine-wood it has valuable tonic astringent properties. It may be administered in quantities of from forty to sixty grammes during the twenty-four hours in congestive pulmonary hemorrhage, and in hemorrhage of the uterus and kidney. It arrests the hemorrhage of the first two stages of phthisis with remarkable promptitude.—*Lancet.*

"OVARIOCLASIE" is the name of a new measure advocated by Porro. It consists in destruction of the tissue of the ovary in cases in which removal of the organ is indicated, but cannot, for some reason, be carried out.

SOME OF THE PRINCIPLES OF CRANIOMETRY.[1]

By FREDERICK PETERSON, M.D.,

ASSISTANT IN THE NERVOUS DEPARTMENTS OF THE NEW YORK POLYCLINIC AND MANHATTAN EYE AND EAR INFIRMARY.

In looking at a collection of skulls, or in examining the heads of a large number of people, one is struck at once by the great variation in their size, shape, and even symmetry, within strictly physiological limits.

A score or more of distinguished anthropologists of the present century have been trying to discover racial distinction in human skulls; but the fact is that there are not so many characteristics of race in the cranium as in other parts of the body, and accordingly there are still wide differences of opinion as regards a scientific craniological classification. Races have been mingling so many thousands of years that cranial dissimilarities are the rule among them even in tribes, and to some extent in families. These diversities of form have been designated as dolichocephalic, mesocephalic, and brachycephalic, words which merely convey an idea of the relation of the length to the breadth of the skull when viewed from above. The antero-posterior is to the biparietal diameter as 100 is to x, is the formula for determining this "cephalic index." All length-breadth indices below 78 are considered dolichocephalic; 78 to 80, mesocephalic; and above 80, brachycephalic. We may assume that the physiological limits of this index are 70 to 90. This is based upon thousands of measurements of skulls by various investigators. Any excess or diminution of these figures must hence be regarded as pathological.

I would merely make passing mention of the fact that, according to latest classifications (Huxley and others), most Europeans and most of the people east of a line drawn from Lapland to Siam are brachycephalic; that Negroes, Australians, English, Irish, and Scandinavians are dolichocephalic, and the Hollanders mesocephalic.

But, while one skull may be narrower or broader than another, there is compensation in other diameters. The dolichocephalic has a greater vertical diameter, for instance, than the brachycephalic skull.

Besides these characteristics something must be said regarding the physiological asymmetry of the skull. The fact that the arms and hands are not symmetrical on the two sides of the body, either in size or function; that the legs and feet are not symmetrical; that the left cerebral hemisphere is larger and more complicated than the right, would naturally lead us to anticipate some slight asymmetry of the two sides of the skull, and the facts of observation support us in the statement that asymmetry is the rule, and perfect symmetry the exception. More than a thousand post-mortem examinations, the examination of several hundred heads, and an inspection of some collections of skulls, such as that of Blumenbach, where I have particularly noted this point, together with the testimony of others, justify me in this assumption.

Asymmetry sometimes reaches extraordinary proportions, often with quite a normal state of brain function, often with marked psychopathic changes. Outside of purely physiological asymmetry we have that depending upon defective development and disease. One of the first of nature's constructive principles in fashioning the skull is the struggle of its contents for volume. Hence, as long ago pointed out by Virchow, premature synostosis of any cranial suture will lead to compensatory deformity. So, too, will arrest of development in any centre of ossification, or a unilateral aplasia or hyperplasia of the skull bones, or of the contents of the skull.

The diseases which most commonly produce cephalic deformation in early life are rachitis and hydrocephalus; in later life, tumors, exostoses, ostitis, etc.; while at all periods of life the shape of the skull is menaced by injuries, from a forceps delivery to a falling brick. The following are some of the commoner designations of well-known cranial deformities:

Macrocephalus, due to hydrocephalus, microcephalus, due either to aplasia of the brain or sutural synostoses, and the peculiar skull of rickets are three forms so familiar that I will not here take the time to describe them.

Oxycephalus, or steeple-shaped skull, is due to synostosis of the parietal with the occipital and temporal bones, with compensatory development in the region of the bregma, and is said to be common among epileptics and born criminals and their families.

Premature union of the frontal suture, resulting in very narrow forehead and great width behind, gives rise to the term trigonocephalus.

Plagiocephalus, or oblique deformity of the head, is due to unilateral synostosis of the frontal with one of the parietal bones.

Chamæocephalus is flat-headedness, said to be frequent among the insane.

Scaphocephalus is probably caused either by too early union of the sagittal suture or by the development of both parietal bones from one centre. Early synostosis of the frontal and sphenoid produces leptocephalus or narrow-headedness.

One of the principles of cranial development being struggle for volume, it is evident that in many cases the more marked the deformity of the skull, the more successful has been the struggle; so that very great cranial deformity is, as a rule, less indicative of psychopathic conditions than a moderate degree. It is difficult indeed, therefore, to define the exact limits of physiological asymmetry on the one hand, and a successful compensation in development on the other, with a pathological distortion between the two. We are accordingly under the necessity of regarding asymmetry of cranial structure as merely significant of a tendency toward mental deterioration. A misshapen skull affords ground for suspicion, but no absolute proof of mental disorder.

It is to be regretted that we have no studies of the psychical histories of tribes accustomed to producing artificial malformations of their heads during development. There are eight or ten species of artificial deformity which have been practised from time immemorial among the lower races of mankind, and are still in vogue among certain Polynesian and American tribes. The disfiguration is accomplished by means of bandages, boards, or masses of clay fastened upon the infantile skull to produce the prevailing fashionable shape.[1] Many of these skulls are to be seen in the famous collections at Paris, Shelton, and Göttingen.

---

[1] Topinard: Anthropology, pp. 178 to 185; trans. by Dr. R. J. H. Bartley. London: Chapman & Hall. 1887.

It may be affirmed that every segment of the skull represents some particular part of the brain lying beneath it. This may be assumed without proclaiming one's self a proselyte of Gall.

It is certainly true that single convolutions have no very marked influence upon the external configuration of the cranium; but they do, however, strongly impress the inner table of the skull, as will be seen upon examination. The indentations upon the inner table are most distinct on the orbital plate of the frontal, the squamous portion of the temporal, and the upper part of the occipital bone. The orbital surface of the orbital plate of the frontal is perfectly smooth. The outer table of the occipital presents no ridges correlated to the convolutional imprints within, but, on the contrary, has ridges for muscular attachment. The external surface of the squamous portion of the temporal bone is, indeed, modified by the size of the convolutions of the temporo-sphenoidal lobe; but on the head this portion of the skull is obscured by the temporalis. Yet although single convolutions do not impress themselves to such an extent upon the outer surface of the skull as to be recognized, this is not altogether the case with groups of convolutions. Groups of convolutions do modify the shape of the skull, do possess visible representation upon its outer surface.

The great recent advance in cerebral localization paves the way to a newer and more scientific, though a more limited, phrenology. Thus the parietal bosses correspond chiefly to the sensory, somewhat to the motor, cortical areas. The dimensions of the forehead have a direct relation to the frontal lobes, the higher intellectual substrata. The left temple has been shown by Benedikt, in one case, to be depressed in congenital aphasia. The parieto-occipital portion of the skull is doubtless modified by the countless sight-memories stored up beneath it. I have myself noted in two or three cases of infantile spastic hemiplegia an alteration in the shape of the skull on the side opposite to the paralysis. I here present cranioscopic drawings in one such case.

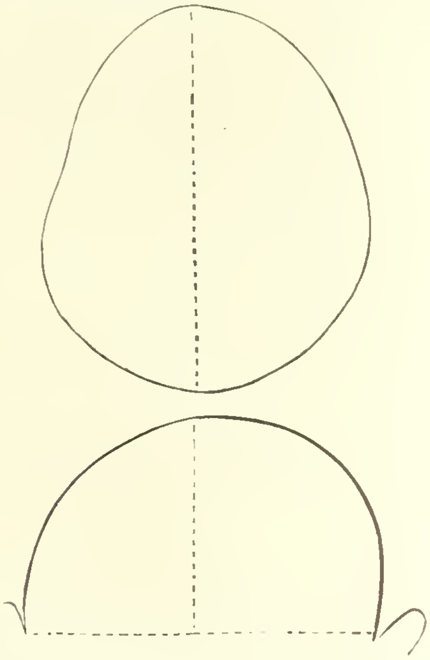

Fig. 1.—Depression of left half of skull in a case of congenital right hemiplegia spastica.

Thus far cerebral localization has been almost entirely directed to sensory-motor functions. Little scientific achievement has been made in the wide domain of ideational localization, yet there is a possibility of its being attained some day. From unfinished studies of mine in melancholia, I think that there is a strong probability of the seat of the disorder being located in the temporo-sphenoidal, and perhaps occipital lobes, and that there may be found in this region the chief cortical centres of the depressing emotions. The musical faculty is probably also situated in the temporo-sphenoidal lobe with the other auditory memories.

Even, however, if the new phrenology is far in the distance, craniometry and cephalometry have at present their importance and application. Virchow,[1] Welcker,[2] Weissbach,[3] Rieger,[4] Zuckerkandl,[5] and others have added much to our precise knowledge of the skull. I owe to my teacher, Professor Moritz Benedikt, a nearer acquaintance with a most interesting and useful science. Though in some sense an enthusiast, he is a learned and scientific man, an excellent mathematician, and an earnest seeker after truth. His long study of craniometry, culminating this year in a volume[6] which may be regarded as a forerunner of other dissertations, places the subject upon exact mathematical foundations, demonstrates that the skull is constructed upon crystallographic principles, and indeed inaugurates a new era in the science.

We are not in a position to practise craniometry proper to any great extent in this country, at least for pathological or forensic purposes, for no collections of the necessary sort exist. Comparative craniologists find at Philadelphia and Washington material for their purposes; but we neurologists have any number of heads at our disposal—normal, insane, and criminal—and there is a wide field for studies in cephalometry.

The two systems of measurement—the craniometrical and cephalometrical—differ but slightly from each other; the former, of course, being the more exact, since every portion of the naked skull is attainable. Both systems, if perfect, require such measurements to be taken as will serve at any time to reconstruct the skull. Geometry and trigonometry are pressed into use. Certain definite points are selected for the arcs and radii, as shown in some of the diagrams (Figs. 2, 3, 4, 5, and 6). It will be seen that the longitudinal, vertical, and horizontal sections of the normal skull all exhibit a certain and definite number of curves. In fact, its whole surface may be considered as composed of an aggregation of small cycloid surfaces, developed and joined together according to fixed biomechanical laws, just as a fruit is evolved on biomechanical principles, with its definite number of seeds and concentric disposition of substance. The object of these notes not being to present a formidable treatise on the triangulation of the skull, but to introduce a few practical ideas, and furnish an incentive for more and better work than has hitherto been done in this country upon this subject, I pass over the long series of craniometrical measurements, and also the thirty-eight cephalometrical formulæ recommended to thorough students by Benedikt, to select those which are absolutely necessary in order to form a just idea of the capacity and symmetry of any head—measurements which ought to be taken in every asylum, upon every patient admitted, and in every prison upon every criminal. Even the asylums of Italy surpass us in this respect. At San Servolo, in Venice, which I visited a year ago, fourteen cephalometrical measurements are taken upon every patient at the time of admission. Figures of this kind become in time of immense value.

I would recommend the eleven following measurements: 1, The circumference; 2, the naso-occipital arc

(Fig. 2, n to t); 3, the naso-bregmatic arc (n to β); 4, the bregmato-lambdoid arc (β to a); 5, the binauricular arc; 6, the antero-posterior diameter (s to o); 7, the greatest transverse diameter (length-breadth index); 8, the binauricular diameter; 9, the two auriculo-bregmatic radii; 10, the facial length; 11, the empirical greatest height (b to β or v).

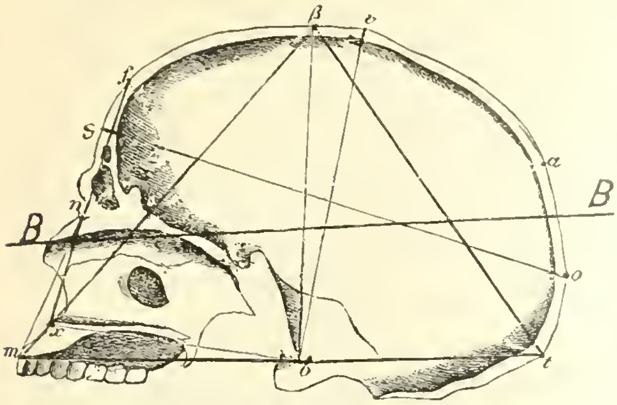

Fig. 2.—*BB*, Broca's visual plane; $m\ \beta\ t$, the triangle for ascertaining the empirical greatest height.

In addition to acquiring these mathematical data, cephaloscopic drawings are invaluable as exhibiting deformity clearly to the eye. Hence the horizontal circumference, naso-occipital curve, and binauricular curve should be taken with a strip of lead, or, what is better, with the instrument devised by Luys[1] (on the principle of the hatter's conformateur), and the curves projected upon paper.

We will now consider each of these eleven points in detail.

1. The circumference of the skull averages 52 ctm. in men, 2 ctm. less in women, with a physiological variation from 48.5 to 57.4. This measurement is taken horizontally around the glabella and the point just above the external occipital protuberance known as the maximum occipital point, from its giving the greatest antero-posterior diameter (Fig 2, s to o). The scalp and hair superadd about 3 ctm.; hence in cephalometry about six per cent. should be deducted to obtain the measure of the skull. (Six per cent. should also be deducted in measurements Nos. 2 and 5.)

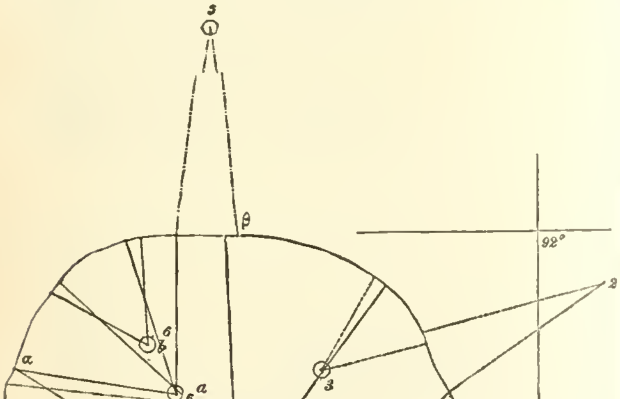

Fig. 3.—Cathetometric projection of vertical median plane, showing eight arcs of circles. (After Benedikt.)

An effort has been made by Welcker, and others, to determine the cubic capacity of the cranium through the relations of some of its diameters or its circumference. But it has been found that the cubic contents vary in different skulls even when the circumferences are equal. It is probable, however, that by the acquisition of long series of cranial diameters and volumes, we will in time arrive at some standard for approximating the quantity of brain in any head. A very rough empirical estimate is that where the circumference of the skull is 50 ctm. its volume will be about one thousand three hundred and fifty cubic centimetres.

2. The naso-occipital arc is measured from the root of the nose to the lowest part of the external occipital protuberance (Fig. 2, n to t). The average is 32 ctm. in men, one less in women, with a physiological variation between 28 and 38.

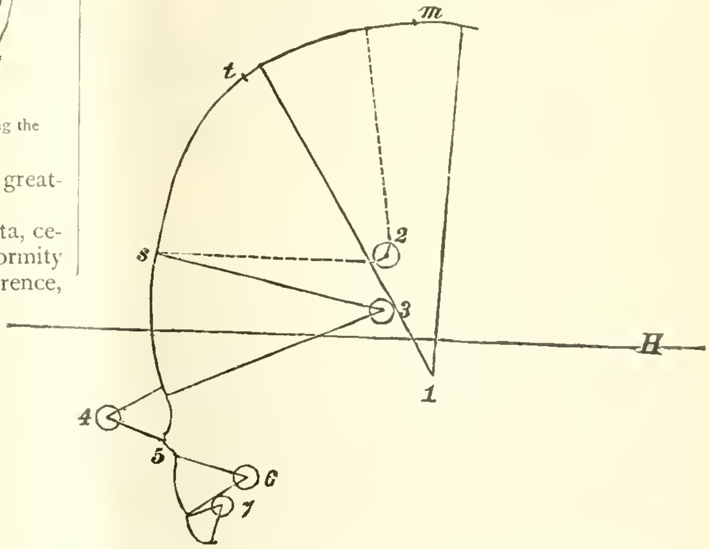

Fig. 4.—Cathetometric projection of left half of a transverse vertical plane perpendicular to the median vertical and horizontal plane, passing through the tip of the mastoid process. Seven arcs of circles shown. (After Benedikt.)

3. The naso-bregmatic, or frontal arc, taken from the root of the nose to the bregma (Fig 2, n to β), averages on the skull about 12.5 ctm. in men, 12 in women, with a physiological variation between 10.9 and 14.9.

4. The bregmato-lambdoid, or parietal arc, which is the measurement of the length of the sagittal suture, and hence the extent of the parietal bones, averages on the skull 12.5 ctm. in men and 6 mm. less in women, with a physiological variation between 9.1 and 14.4 (Fig 2, β to a). The bregma and lambda are easily found on the head after some education of the fingers.

5. The binauricular arc is measured vertically over the top of the skull, following Broca's vertical line, between the two auditory meatuses. We select at the meatus either a point on the anterior rim between the middle and posterior roots of the zygomatic process, easily felt on the head just behind the maxillary articulation, or a point on the posterior superior rim corresponding to a small depression, both of which are fixed points, and differ but slightly in elevation. The average is about thirty-two centimetres on the skull in men, one less in women, with a physiological variation between 28.4 and 35.

6. The greatest antero-posterior diameter is taken from the glabella, or middle of the forehead, to the maximal occipital point (Fig. 2, s to o). It averages 17.7 ctm. on the skull of men, 5 mm. less in women, with a physiological variation between 16.5 and 19.

7. The greatest transverse diameter is sometimes between the tubera parietalia, sometimes between the upper portions of the temporal bones. It averages 14.6 ctm. in men and 14 in women, with a physiological variation between 13 and 16.5. As before mentioned, the length-breadth index is obtained from these two diameters, Nos. 6 and 7.

---

[1] Recherches sur la mensuration de la tête, etc. Paris: Baillière et frère, 1886. The expense of the instrument is about nine hundred francs in Paris.

8. The binauricular diameter is taken between either of the points described, on the rims of the auditory meatuses. It averages 12.4 ctm. in men, 5 mm. less in women, and the physiological variation is between 10.9 and 13.9. In measuring the head, the scalp averages 5 mm. in thickness; hence in the larger diameters (Nos. 6 and 7) one ctm. must be deducted to get the figures for the skull, while in shorter measurements (such as Nos. 8 and 9) it is sufficient to subtract 7 mm.

9. The auriculo-bregmatic radius of each side is taken from the usual point at the meatus to the bregma. By calculation from these radii and the binauricular diameter, we are enabled to ascertain the distance of the bregma from a point in the median plane, half-way between the two meatuses; this distance averages in the normal skull 11.7 ctm., with a physiological variation between 10 and 12.65.

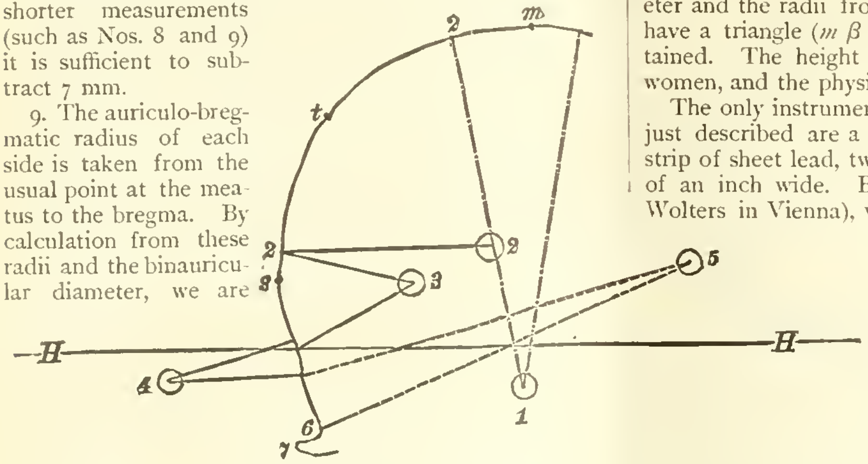

FIG. 5.—Same as Fig. 4, but about twenty millimetres farther forward, through middle of articular surface of inferior maxilla. (After Benedikt.)

10. The facial length is measured from the nasal root to the lowest median point of the inferior maxilla. It averages 12.37, with a physiological variation between 10.5 and 14.4. Including as it does the teeth, infants and the aged are debarred from this measurement. Dolichocephalic heads have, as a rule, narrow, and brachycephalic, broad faces. Something should here be said concerning prognathism, of which there are several forms. The best method of determining it is to measure the angle made by a line drawn from the nasal root to the junction of the inferior nasal spine and alveolar process (Fig. 2, $n\ x$), with a vertical line dropped from the nasal root to Broca's horizontal. It is found that every normal skull exhibits this subnasal prognathism, but there is wide variation in degree. Extraordinary prognathism, orthognathism, and opisthognathism, meaning extreme projection, straightness, or inclination backward of the subnasal line, are pathological.

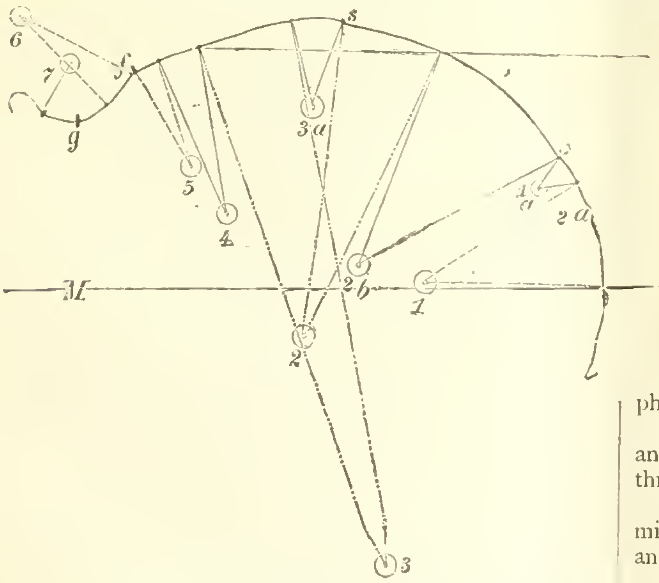

FIG. 6.—Projection of right half of a horizontal section through a skull on Broca's visual plane, showing seven arcs of circles. (After Benedikt.)

11. The empirical greatest height of the head is an approximate measurement of the distance between the basion and vertex of the skull (Fig. 2, b to β or γ). A line from the external occipital protuberance to the lowest median point of the superior maxilla, just above the incisors (Fig. 2, t to m), passes almost directly through the basion. Hence, in cephalometry, by taking this diameter and the radii from each extremity to the bregma, we have a triangle ($m\ \beta\ t$) whose height ($b\ \beta$) is easily ascertained. The height averages 13.3 ctm. in men, 12.3 in women, and the physiological variation is from 11.5 to 15.

The only instruments necessary for obtaining the data just described are a pair of calipers, the tape-line, and a strip of sheet lead, two feet long by half or three-quarters of an inch wide. Benedikt's calipers (manufactured by Wolters in Vienna), which are here exhibited, are to be recommended for their exactness (Fig. 7).

For a more careful study of cephalometry and the acquisition of further data not given here, two other instruments are needed, which have been devised by Benedikt, and which are here presented to the Society for inspection. One of these is applied to the orbits for the purpose of determining Broca's visual plane (made by Ploessel in Vienna, Fig. 8), and the other is a complicated instrument, designated as the pyramid apparatus (manufactured by Wolters, Fig. 9), for obtaining the exact distance of any point on the side of the skull to the vertical median plane, without the aid of which one would have to make a very tedious and intricate mathematical calculation. This is of particular service in the accurate determination of the amount of asymmetry.

In craniometry proper, still other apparatus is required, viz., one for volumetric estimates, with water in a thin rubber bag, and a cathetometric armamentarium, consisting of a craniofixator, cranioepigraph, telescopic levelling apparatus, and an instrument for projection, by means of which every arc and radius, and every portion of the bones and sutures may be exactly studied, measured, and drawn. With this instrument Benedikt makes some one hundred and twenty measurements of every skull. By its use the relations of normal and pathological skulls, and the relations of comparative craniology may be defined with scientific precision.

A knowledge of some of the pathological and forensic uses of the cephalometrical measurements here recommended for asylum and prison physicians may be gathered from the following facts:

It may be stated as a general rule that the defective and delinquent classes are recruited from the inferior anthropological portions of our race.

As regards the circumference of the head, excessive minima and maxima are more frequent in the insane and in criminals than in the normal.

With regard to volume, taking 1,500 c.c., as the normal cubage of the male skull, and 200 c.c. less as that of the female, with a physiological variation between 1,200 and 1,750, Schaffhausen and Benedikt found 175 criminal crania below the type; 203 skulls of insane men and women, measured by Zuckerkandl, Sommer, and Benedikt, were somewhat above the type, while 14 idiot skulls were, of course, far below normal. Schuppmann's 30 epileptic skulls gave rather a hypertypical result. But neither in insane nor in epileptics do the pathological characteristics lie essentially in their comparative cranial volume.

The naso-bregmatic or frontal arc, representing the height and development of the frontal lobes, presents minimal measurements more often in the insane and in criminal than in the normal series.

The bregmato-lambdoid or parietal arc exhibits extremes of minimal and maximal measurements more commonly in the defective and delinquent classes than in the normal. Here, also, the minimal are more frequent. These facts are thought by Benedikt to point to an aplastic development of the frontal and parietal lobes among the insane and criminals. He finds an atypic shortness of the parietal arc a characteristic, though not absolutely constant, observation in epilepsy. Less than 3 ctm. shortening is not to be noticed.

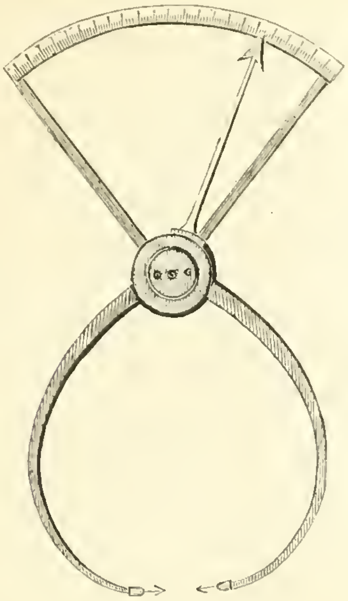

FIG. 7.

The arc from the lambda to the external occipital protuberance is worthy of study, particularly in cases of congenital or early acquired blindness, now that we know the cunei to be the principal visual centres; and the arcs of the temporal bones also demand investigation as regards their relation to similar conditions of deafness.

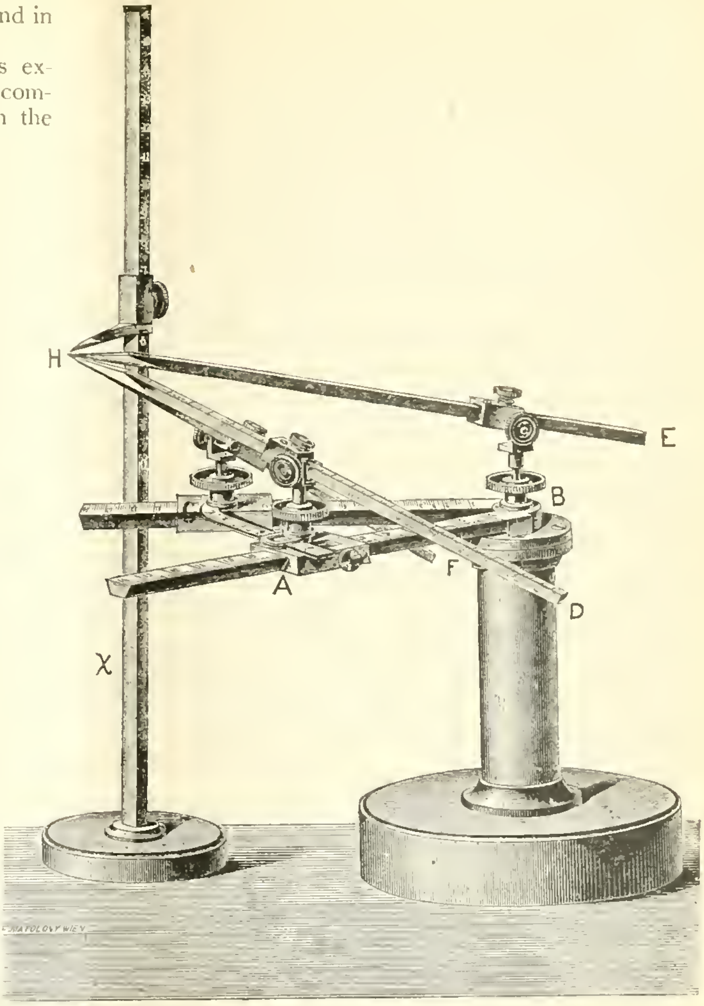

FIG. 9.—To ascertain the amount of asymmetry, that is, the distance of any point on the side of the skull to the median vertical plane, measure the distance to the asymmetrical bump from any three points in the median plane, and also the distances of said three points from each other. We then have all the sides of a triangular pyramid whose altitude is to be determined, its base being in the median plane. By transferring our measurements to this apparatus the height is quickly learned. *A*, *B*, *C* is the base of the pyramid. On the arms, *D*, *E*, *F*, the distances to the asymmetrical point are marked off, their points brought together at *H*, and by bringing the sliding point on the epigraph, *X*, also to *H*, the height may be speedily read off on the upright column of *X*.

As regards the length of the head, the measurements of Zuckerkandl and others in 119 male insane and 177 male criminal skulls show that maxima and minima are in these more common than in any normal series. The same is true of the breadth of the head. Minimal excess is slightly more frequent than maximal in defective and delinquent classes. The same skulls presented also enormously excessive dolichocephaly, and to a considerable extent excessive brachycephaly, when examined as to their cephalic index. The length-breadth index is indeed very useful as a means of judging of atypic and pathological cases. Now that Alphonse Bertillon's anthropometric system of identification of criminals[1] is being so generally adopted by different nations, students of craniology will soon have an enormous mass of material to draw upon in the study of the cephalic index, for two of his measurements are the length and breadth of the head. In the series of 100 cephalometric and cephaloscopic examinations[2] of people, mostly insane (from patients of mine in the Hudson River State Hospital), that I present here to-night, a number of these extreme variations from the physiological limits will be observed, as well as great asymmetry.

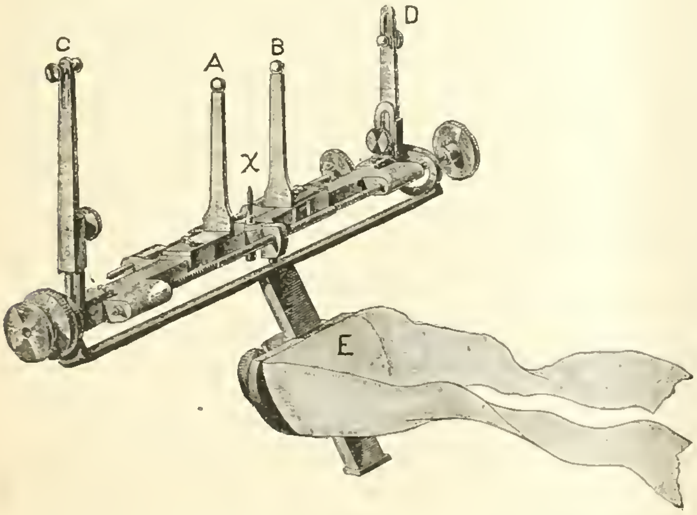

FIG. 8.—*A* and *B* are applied to the inner canthi of the eye, *C* and *D* to the middle of the outer orbital rims. *X* is a pencil of lead which marks a point upon the nose. *E* is a part for supporting the apparatus in position. The points *C*, *D*, and *X* are marked upon the face, and the triangle thus made is measured. This triangle lies in Broca's visual plane, and the whole plane and its relations to the rest of the head may be determined by taking various radii from these three points.

Excessive prognathism is found among criminals, in microcephali and in cases of hemi- and paraplegia spastica infantilis. Skulls known as crania progenæa[1] have considerable pathological significance. In these the lower teeth project beyond the upper, and the inferior maxillary angle is obtuse, due probably, to aplasia of the upper, or hyperplasia of the lower, maxilla.

[1] Bertillon: New Method for Identification of Criminals by Anthropometric Descriptions. Address at International Prison Congress, Rome, 1885. Trans. by G. Muller, Joliet Prison, Illinois, 1887.

[2] To be especially studied when the collection is larger.

The demonstration of the empirical greatest height is often quite valuable as an index of degenerative and neuropathic types. The skulls of insane and criminals are found to be, as a rule, lower than normal. Hence an abnormally low skull may be considered as showing a tendency to crime or insanity. Occasionally there is excessive height in these classes. Oxycephalus may be cited as an example.

The following general statements may be made: Zuckerkandl's measurements of 127 insane skulls demonstrated atypical variations in 103, or more than eighty-one per cent. Bordier found that fifty-eight per cent. of a number of skulls of murderers presented abnormalities of construction.

A skull below the normal type in volume belongs to an abnormal individual.

Under-typical measurements of the head should always lead us to entertain the suspicion of defective cerebration.

Abnormal smallness of any part of the skull permits the conclusion that the part of the brain in its neighborhood is imperfectly developed.

Excessive development of the head has a double signification. It is always pathological, but may mean abnormality of brain or successful compensation. Wormian bones are also doubly significant. They either represent a pathological process or a successful effort of nature in repair.

Hemiplegia spastica infantilis, epilepsy, and intellectual or ethic weakness often exhibit unilateral aplasia of the skull.

The skull is representative of the brain only during the years of its development, and it must be remembered that psychopathic deterioration often has its inception subsequent to the completion of the process, when no impression can be made upon its bony walls.

In conclusion, I will state that the object of this paper is to present some of the most recent thought upon the science of craniometry, to provide a simple system of measurements for adoption in institutions, to introduce new instruments and data for mathematical precision, and to furnish an incentive to our own students to carry on scientific researches in this direction.

34 East Twenty-first Street.

Furrows in the Finger-nails.—Dr. J. W. Bovee, of Washington, D. C., writes: "I have been considerably interested in the condition mentioned in a recent number of The Medical Record as Furrows on the Finger-nails. I do not think they have received attention, except casual mention by a few dermatologists. I have seen this condition many times after an attack of some acute disease. In a case of diphtheria that was quite severe, the transverse grooves were very distinct on both finger-nails and toe-nails, and in a case of acute articular rheumatism the transverse grooves continued to be formed for nearly a year subsequent to recovery from the attack of rheumatism. This appearance of the finger-nails I have noticed in twenty different children, shortly after recovery from rotheln, and in a few of these, probably about five, I noticed the grooves in the toe-nails, and was assured by the parents that in that location also the grooves appeared only after the child was well. In the spring of 1885, I had a severe attack of intermittent fever, closely followed by German measles, and I had a good opportunity of watching the progress of these grooves from the matrices to the free ends of my finger-nails. Again, after quite a severe attack of sciatica, last January, I noticed these transverse furrows in my finger-nails, some of which still linger near the free extremities."

PUERPERAL SEPSIS.[1]

By D. O. THOMAS, M.D.,
MINNEAPOLIS, MINN.

Puerperal sepsis is a term which presents a clinical picture of variegated aspects, supposed by some physicians to be simple and intelligible enough to them without even their glasses, but regarded by others as complex and incomprehensible even with the aid of a microscope. Sepsis is a word used in connection with accurate or scientific medicine; yet it is not always that we are sure what is meant when we hear it employed, for the range of its meaning is so wide that it is often applied to the result of "absorption," "contagion," and "infection."

As practitioners, we are not expected to be special expounders of the various and unsettled theories of septicæmia. We are more immediately concerned with the practical in medicine; and I have selected this subject mainly with the intention of presenting one suggestion with reference to its treatment. But preliminary to this, we must consider the nature of puerperal sepsis. He is a mere empiric who is satisfied to treat only the symptoms of disease. Rational therapeutics demand that we should be equally interested in the cause and nature, the origin and development, of disease; so that we can intelligently treat the patient and prevent a disorder becoming a disease. It is also our duty to study the methods of nature in ridding the human system, when once infected, of sepsis and its effects. The physician of the past was guided mainly by symptoms, but the day is not far distant when diseases will be classified no longer by symptoms, but by causes.

It had been known for ages that puerperal fever was an infectious disease, and that fact had been sadly demonstrated by fearful epidemics in hospitals, and also in private practice; but the cause of the outbreaks was only conjectured. Within the memory of the present generation, Meigs said: "What the real principle of this epidemy is, I believe there is no man that can say." Long before bacteria were discovered, it was known that cadaveric poison and the infection of zymotic diseases produced sepsis; and the wounds inflicted by the claws of carnivorous beasts, and the scratches from the beaks and talons of carnivorous birds, had been observed to result in blood-poisoning. But how much more intelligibly do we comprehend septic infection in the light of bacteriology! Though it is not perhaps universally conceded that puerperal fever is caused by microbes, and though no typical disease has been produced by the inoculation of the lower animals with the microbes found in puerperal sepsis, yet enough has been demonstrated to establish the bacterial origin of all infectious diseases, and I therefore venture to consider puerperal fever from this standpoint. This position, I am aware, is not without its difficulties, but this is partly due to our ignorance of chemical and biological laws as applied to protozoic organisms. We are not able to detect all the subtle changes which take place in the blood from health to disease. Our knowledge of physiological chemistry is not able to tell us always when the blood is normal, nor what alkaloids are developed by overcrowding in hospitals. We are not able to say what is the normal habitat and nature of the microbes; neither can we explain the susceptibility to, or immunity of, one race or person from infectious diseases. For example, the white man is susceptible to yellow fever, while the negro is almost entirely exempt; while in epidemic cholera and small-pox the negro is more seriously affected than the Caucasian. Again, the negro has almost absolute immunity from syphilis, while he is far more susceptible to tuberculosis. Neither are we able, on bacterial grounds, to account for all personal idiosyncrasies, and some hereditary tendencies.

The study of bacteriology is, as yet, in its infancy, and the conclusions arrived at are few, and mostly incomplete; yet the proof, direct and indirect, is sufficiently convincing of the bacterial origin of such diseases as anthrax, tuberculosis, leprosy, and syphilis. Dr. Joseph Coats thinks the proof sufficient that all infectious diseases are due to specific micro-organisms. He admits, however, that this is not certain of all infective diseases, and alludes especially "to the spreading character of many skin diseases," discussed recently by Jonathan Hutchinson, and states that he is "far from assuming that in all those cases micro-organisms are concerned." But it has been proved beyond the possibility of a doubt that anthrax and tuberculosis are caused by micro-organisms; for inoculations of the respective germs from gelatine cultures have produced the typical disease, with all its characteristic pathological lesions, in the lower animals. About the same thing may be said of erysipelas. It is true that a specific puerperal fever by inoculation has not been so produced in the lower animals, but this is of very little significance, since those animals may have as much immunity from the microbes as the negro has from yellow fever. Some animals are more susceptible to certain diseases than others; for inoculations of lupus produce symptoms of general tuberculosis in the guinea-pig, while they produce only an ulcer or cold abscess in the rabbit.

---

[1] Read at a meeting of the Medical Society held April 16, 1888.

What, then, is the indirect proof that bacteria are factors in the production of puerperal fever? In the first place, it has been observed that when the lochia of a healthy puerpera are examined the microscope discovers no microbes, or only a few; but, on the other hand, before and after the invasion of puerperal infection the lochia literally swarm with them, and each drop of vaginal secretion becomes a nest of microbes. Pasteur has been able to discover in the blood, before death, the same micro-organisms which apparently cause the disease, and which the post-mortem examination finds in all the pathological lesions: in the exudations of the pleuræ and peritoneum, in the pus of the lymphatics and blood-vessels, and in the metastatic abscesses of the mammæ and deep cellular tissues. Still further, "Pasteur, in the services of Harvieux and Championnière, has been able, by the simple microscopic examinations of the lochia, to predict the appearance of affections before the clinicians even suspected them." The groupings or arrangements of the micro-organisms in gelatine cultures are similar to those found in post-mortem lesions, demonstrating, like the "handwriting on the wall," the cause of the disease. It must be admitted that to workers in bacteriology we are indebted for all recently gained knowledge in the pathology of puerperal fever, and it is to them that we must look for a differentiation of the disease.

The term puerperal fever is too extensive for accuracy, for various diseases may attend the puerpera during puerperium. It is doubtful if there is a specific puerperal fever peculiar only to the puerperal period; but such diseases as small-pox, measles, scarlet fever, erysipelas, and diphtheria attending the puerperal stage are frequently accompanied with septicæmia, and consequently called puerperal fever. It is possible, of course, for a woman to take any of these during confinement, and though they generally produce fatal puerperal sepsis, they may occasionally run their course without the sign of septicæmia. To give a perfect classification of puerperal fever at present is perhaps impossible, because the disease is frequently complex, arising from mixed infection. The disease may originate in three ways: 1. By absorption of the secretions. 2. By contagion. 3. By infection from zymotic diseases.

1. *By absorption.*—The question has been frequently discussed whether puerperal fever is both auto-genetic and hetero-genetic; or, in other words, whether it arises *de novo* without contagion. It is argued that, as microbes are essential to produce sepsis or decomposition, without their presence disease is impossible, and that therefore puerperal fever cannot be auto-genetic. But it must be admitted that arrest of secretion and excretion are frequently factors in the production of puerperal fever. The patient takes cold, or has a chill; instantly the secretions fail, the temperature rises, the suppressed lochia are absorbed, and the condition goes from bad to worse. If the disease is not auto-genetic, why should the statistics show that, owing to exposure to cold, puerperal fever is more prevalent in winter than in summer? The condition of the puerpera, physically, is inviting to disease; for, before delivery all the organs are hypertrophied, and are strained to the utmost to maintain the equilibrium, and supply the demand of mother and fœtus. But, after delivery all the organs become atrophied and the emunctories of the body are severely taxed to carry away the waste material, so that when secretion and excretion are impeded or fail, the *débris* rapidly accumulate and systemic disturbance prevails. This much is evident; but it must be observed further that a puerperal woman is a wounded woman. Cruveilhier very properly pointed out the exact analogy between the uterine wound and a stump after amputation, with the added and still greater danger from more or less inevitable wounds and abrasions of the cervix and vagina. It is quite possible, then, for these to become avenues of infection by means of contagion from without or absorption from within. It is well known that the lochia of even a healthy puerpera, injected into the lower animals, causes profound systemic disturbance. Even lymph so injected is dangerous, causing fever and resulting in toxæmia similar to that of many poisonous vegetable alkaloids. When a puerpera is so affected by absorption of the lochia, no germs are seen in the blood, except possibly late in the course of the disease, and then very few. The disease may run its course with lightning-like rapidity, and the patient may be dead in thirty-six or forty-eight hours; but the post-mortem furnishes no pathological lesions save slight congestions—nothing to tell the story, or cause of death. The post-mortem appearance is somewhat similar to that of an alkaloid poison. In death from belladonna or digitalis the pathological changes are few.

After such a death, if the blood is injected into another animal it does not produce a similar condition, *i.e.*, belladonna or digitalis poisoning. In like manner the blood of a septicæmic patient, when injected, though it produces septicæmia, does not produce a specific disease unless there are bacteria in the injected blood. Simple septicæmia is analogous to traumatic or surgical fever. After operations of any importance there is more or less fever from absorption of lymph, even when the wound is treated antiseptically. In connection with puerperal infection we often speak of "absorption," but I feel that it is not always the correct word. "Absorption" is a proper term in connection with inert material. There are almost always bacteria in the vagina, and where there is possible access they need not be absorbed—they will penetrate the wound by their own energy. When a woman dies suddenly of septicæmia from absorption and no pathological changes are found, we are not able to detect the poison readily and announce the cause of death by a chemical examination, as in strychnia poisoning. However, more active researches have been carried on in the department of physiological chemistry of late years, and the action of subtle poisons is more closely observed. Bearing on this department of our subject, I may say that Dr. L. Bourget has lately isolated ptomaines from the urine of several women suffering with puerperal fever, and obtained reactions similar to those of alkaloids and ptomaines. It cannot be doubted that the toxic material in the breath, and effluvia of the air, when allowed to accumulate, frequently compromise the recovery of the puerpera. It is certain that there is morbific matter in every wound, for a wound otherwise healthy often refuses to heal for want of drainage. This is the condition at first when simple arrest of secretion takes place in the puerpera; but this condition is frequently complicated sooner or later by contagion.

2. *Contagion.*—There is a difference, at least theoretically, between simple septicæmia from absorption, and infection from contagion. In simple absorption the mor-

bific matter has no power of multiplying itself, and of increasing its virulence, but once absorbed it works directly on the circulation, producing toxæmia. In contagion the poison extends from a localized centre, and, after a period of incubation, reproduces itself with wonderful rapidity. If, for instance, the microbe of erysipelas is communicated by digital examination, it spreads from a localized centre in the parturient canal by means of the lymphatics, and it is attended by inflammation and fever. The wounds of the vagina soon assume an unhealthy appearance and become covered with a dirty yellowish deposit, and the neighboring tissues become œdematous and infiltrated. If the disease is localized in the vagina we have, first, puerperal vaginitis. It may, however, ascend and involve the endometrium, the tubes, and peritoneum; or, as is more probable, the inflammation may involve the deeper cellular tissues—the œdema impedes capillary circulation, and consequently the mucous membrane will become soft and sloughy, and the uterine wound covered with vegetations, and phlebitis and cellulitis will be followed by abscesses. The combat is between the resistance of the system and the power of the contagion, or bacteria; and the severity of the disease is generally proportionate to the territory invaded by the inflammation; but in septicæmia the severity of the attack is in accordance with the amount and virulence of the septic matter absorbed. The ingestion of putrid sausages, old bacon, and cheese is deleterious and fatal according to the amount absorbed. It appears that the system will tolerate with impunity a small amount of the most deadly poisons. The poison even of a scorpion is not fatal except in certain quantity. When a scorpion is allowed to strike fowls, the first and second die, but the third fowl generally survives the attack—demonstrating that the poison of the exhausted scorpion has no power of multiplying itself. In the case of the puerpera we have no means of determining the amount of septic matter absorbed, but we are sure (other things being considered) that the amount absorbed is in direct ratio to the gravity of the disease. It is well known that puerperal septicæmia occurs more often in primiparæ than in multiparæ, because in their case more wounds and abrasions take place in the parturient canal, rendering thus the avenues of absorption more numerous. According to our present knowledge, there is no way of predicting in what way the disease will spread, either in or from the parturient canal, because this depends on the kind of microbes involved, their law of propagation, and the resistance of the patient. When the contagion is once established it spreads rapidly by means of the blood-vessels, and especially the lymphatics; for the uterus may not improperly be compared to a vast lymphatic gland, with its mucous membrane and tissue interwoven into a plexus of lymph-vessels.

After a patient has succumbed to puerperal fever, pain and intermission and exacerbation of fever accompany the progress of the disease. The paroxysms are due probably, as in malaria, to segmentation of the microbes and the setting free of new micro-organisms, which in turn undergo a similar process of development and reproduction, until one brood after another pass by the lymphatics, through the thoracic duct, into the circulation. Finally, all the blood-clots and emboli, being invaded by microbes, become suppurated, and phlebitis fills the utero-ovarian veins with pus, and subsequently abscesses and exudations are established in remote parts of the body.

In septicæmia the germ varieties correspond to the degree and development of the disease. According to Pasteur and Doleris, two sorts of organisms preside over infection: "1, the cylindrical septic bacteria, which induce rapid septicæmia; and, 2, the micrococcus, which begins at a point and then is harmless, later forms in couples and determines suppuration, later still assumes the form of *chapelet de grain*, and causes attenuated variety of septicæmia." In this latter form the micrococcus greatly impoverishes the blood; the corpuscles are decolorized and deprived of hæmatin, and the system becomes loaded with the toxic products of the germs. Anticipating a thought on the treatment of puerperal sepsis, may I ask how does the bacterium kill the patient? Is it not possible that death from absorption and bacterial infection results in the same way, *i.e.*, that the microbe itself is not the direct cause of death, but the morbific substance and gases it generates; and that, therefore, the presence of bacteria is not necessarily fatal if the system can be made to expel their toxic product? What is the diaphoresis of hectic fever but the result of an inward struggle to expel the accumulated product of suppuration, which threatens daily to bring on toxæmia? As the fight is prolonged the patient becomes exhausted, and the system has no strength to expel the poison, which remains as an irritant. Much may be accomplished by antiseptics to avoid contagion, but antiseptic cleanliness is no absolute safeguard against infection.

3. *Infectious or zymotic diseases.*—It will not be questioned that, in spite of the most diligent antiseptic precaution, a puerpera may take scarlet fever, diphtheria, erysipelas, small-pox, measles, or typhoid. An invasion of any of these diseases may be accompanied with sepsis. Indeed, it has been found that not only the germs of these diseases but all air-living germs prepare the soil for the micrococci of suppuration, and different bacteria are frequently discovered in the same abscess. It is possible for a puerpera to have measles, scarlet fever, or any infectious disease named without septicæmia, but this is not generally the case. During the puerperal period there is so much waste product in the system that the infection of a zymotic disease serves as a match to the fuel. In cases where scarlet fever takes place, they generally occur during the first week of the puerperium, and they become rarer and less dangerous at a later period. We often have sepsis in two weeks after delivery. The patient takes cold in two or three weeks after parturition, and, expecting to get better, neglects to send for a physician, and consequently septicæmia sets in. In many cases the physician is not to be blamed, for he is not accountable for the careless exposure of the patient, nor for her, perhaps, unfortunate faulty hygienic surroundings. Septicæmia sometimes sets in, notwithstanding the greatest antiseptic precaution on the part of the physician, for all the elements of infection are not under his control.

Treatment.—I need not say in the line of treatment that the management of puerperal cases must be strictly antiseptic. Antiseptic precautions have been attended with wonderful results. There was a time when the mortality from puerperal fever in one of the Paris hospitals was about 1 in 10, but now it is only 1 in 250; and what wonder when one forceps is known to have produced fatal infection in sixteen cases successively; while, on the other hand, by means of antiseptic precaution physicians have gone from the dissecting-table to perform instrumental delivery, with favorable results. Since antiseptics reduce the mortality so wonderfully in the large and crowded hospitals, it is our duty to familiarize ourselves with the established facts of bacteriology, and especially with the principles of antiseptics. What, then, are the conditions under which septicæmia occurs? Workers in bacteriology have discovered by gelatine cultures that the following conditions are essential. Observe that each condition may be present in the case of a puerpera, rendering her that much more liable to the disease:

There must be: 1. Bacteria. 2. Proper soil, the culture-fluid in which bacteria may propagate themselves. Knowing what fine culture-fluid blood and lymph make, it is seen that there is in the puerperal secretions all that the parasites require. 3. Proper temperature. If the culture-fluid is too cold or too hot, the propagation of bacterial culture is impeded; but at the temperature of the body their incubation and segmentation is easily effected. 4. Alkalinity. Certain bacteria require an alkaline medium for propagation. In order to transfer the cholera bacillus, for instance, to the intestinal canal of a dog, the acidity of the stomach, as well as the antiseptic bile, must be overcome. The former is generally accomplished by a heavy dose of bicarbonate of potash, or some other alkali; and the latter is impeded by a dose of opium or by ligation of the bile-duct. In the case of the puerpera the usual habitat of the germ is the vagina, and it has been observed that the lochia are alkaline for a few days after delivery, rendering the condition more favorable to septicæmia. 5. Lack of oxygen. Some micrococci cannot propagate themselves when oxygen is abundant. This observation is well established by clinical experience, for pent-up rooms and overcrowded hospitals are the battlefields of septicæmia. Inasmuch as we see all the conditions requisite for septicæmia present in the puerpera, our chief concern should be to exclude bacteria.

The best prophylactic, possibly, would be for general practitioners to decline accouchement cases when there is the slightest possibility of carrying infection. It is not right for the man entrusted with human life to jeopardize a puerperal case by attending zymotic cases simultaneously. A person cannot disinfect himself, as he should, several times a day. It is true that many physicians wash their hands in a bichloride solution, brush their finger-nails, and change their clothes (a process simple enough to be repeated several times a day), and pride themselves on being antiseptically clean! But is that much only worthy of the name disinfection? There is still another source of danger—the gloves. Let us consider how it is in private practice. A physician, for instance, examines the throat of a scarlatina patient, the child possibly coughs in his face, or the saliva gets on his hand. Before he leaves he washes his hands very thoroughly, and uses the towel to his own satisfaction. Now, even if his hands were clean, is not the towel liable to infect them again? But he puts on his gloves and goes home, perhaps to wash more thoroughly and use his own towel; but he wears the same gloves again, and his next accouchement case is seized with sepsis. Our fur-lined gloves keep the hands perspiring, and are ready to give and take bacteria. It is known that septic parasites may adhere to the whole surface of the body, and may be communicated even by the breath; so a change of clothing and gloves is not a sufficient precaution, without a thorough medicated bath and fumigation or open-air exercise, to prevent infection by means of the breath. Wounds are dressed antiseptically, and the suggestion is not improper that antiseptic medicine, sooner or later, will require the physician, when waiting on infectious cases, to provide himself with a suit, gloves, and head-dress, so constructed as to render his entire person aseptic.

After confinement the patient should be placed in the most favorable condition. Ergot and quinine should be given to secure contraction and facilitate involution of the uterus, for the os uteri is always found patent in septicæmia. Everything in the way of drinks should be warm, and if the lochia are scanty, hot applications should be put to the hypogastrium. To oxygenize the blood there should be good ventilation—fresh air, but no draught. If everything is favorable, no medication is required. But, on the other hand, if the patient takes a chill, the temperature rises, the lochia are suppressed, the mammary secretion fails, the skin and mouth become dry, general symptoms of distress and pain appear, and septicæmia sets in. Now, if the case is allowed to run its course without any medication, what is nature's method of combating the septicæmia or toxæmia? Is it not to prevent further absorption, if possible, by bringing on healthy granulating cells in the wound? or, where the strength is sufficient and granulation impossible, does she not turn the wound into an abscess incapable of absorbing? Then, as to the poison already absorbed, does not nature attenuate it by rise of temperature, and attempt to expel it by forced diaphoresis? It seems to me, then, that the rational treatment of septicæmia is to anticipate nature's plan, and aid her in her method, and do at once what nature would do eventually, *i.e.*, expel the bacterial poison by judicious diaphoresis. To begin, let a full dose of antipyrin be administered, and let the diaphoresis be continued by minute doses of pilocarpus, combined with antipyrin if necessary. To aid perspiration, warm drinks and hot applications can be used; and to prevent further absorption, if the lochia are offensive, the vaginal douche can be employed, or the uterus may be examined and washed through a soft catheter, if necessary. If this is done very gently at first, the uterus generally will tolerate it without any bad effects. The danger from intra-uterine injection arises from surprising the uterus—the water being injected too suddenly at first, and the organ shocked. When injections are called for, several injections should be given in twenty-four hours, so as to thoroughly wash out the rapidly increasing poison. He who has a case of puerperal sepsis on hand needs to be up early and late, and to be most diligent in attendance, so as to superintend the case personally.

It has been customary to administer large doses of quinine with the idea of reducing temperature, but when the pyrexia is not of malarial origin the use of quinine is empirical, and frequently contra-indicated by gastric disturbance. If it is tolerated, it is well to give it as a tonic, but it does not modify the course of the disease, and better results can be obtained by free use of brandy or whiskey. Small doses are only of small value, but given freely, as advocated by Runge, alcohol, so to speak, saturates the system, sustains the strength of the patient, and by its affinity for fat penetrates the cells, checks metamorphosis of tissue, and retards bacterial activity. In advocating diaphoresis I do not wish to be understood as favoring an excessive and indefinite continuance of the method, but only for three or four days after the onset of the disease; and then it must not be pushed to the exclusion of sleep. Early in the course of the disease it is safe to give antipyrin in full doses, and encourage diaphoresis, but when the patient has been fighting with disease for a long time the heart's action becomes feeble, and stimulants will serve a better purpose than sedatives. However, if the patient takes nourishment well, and her strength is sustained, moderate diaphoresis may be kept up. To promote this, and also to improve the appetite, it is well to accompany the administration of alcohol with frequent tepid sponge-baths. I have not entered into the details of treatment, hence have said nothing of the place of opium in puerperal peritonitis, but have endeavored to emphasize one idea only, viz., the propriety of following nature's method, and instead of attempting to kill the poison in the system, aim rather to expel it by the main avenues of excretion—the skin, kidneys, and bowels. All of these we can assist. Respiration is another important avenue, but it needs no better medication than good ventilation. Briefly stated, I think that, besides local treatment of the parturient canal, the indications are: moderate diaphoresis, refreshing sleep, and good nutrition.

WEIL'S DISEASE, described by Dr. Weil in 1886, has been studied by Fiedler, who thinks it is not a form of typhoid fever, but a distinct disorder (*Deut. Archiv*, vol. xlii., p. 281). It is an acute infectious or toxic affection. The disease begins suddenly, without prodromal symptoms, but often with a chill. The constant symptoms are fever, headache, gastric disturbance, jaundice, and muscular pain, especially in the calves. The fever has a typical course, and lasts eight or ten days. Relapses have been observed. The spleen and liver are generally but not always swollen; the liver often becomes tender on pressure. Nephritis is often observed; herpes and erythema occur at times. The prognosis is generally favorable. Weil's disease is generally seen in hot weather, and men in the prime of life are the most subject to it. The cause is quite unknown, but butchers appear most liable to the disease, judging from the scanty statistics already at the disposal of the physicians who have studied Weil's disease.—*British Medical Journal.*

ESERINE AND CORNEAL ULCERS.[1]

By HERBERT HARLAN, A.M., M.D.,

SURGEON TO THE PRESBYTERIAN EYE, EAR, AND THROAT CHARITY HOSPITAL, BALTIMORE; DEMONSTRATOR OF ANATOMY IN THE UNIVERSITY OF MARYLAND.

Having been much impressed with the value of eserine in corneal ulcerations, and finding that very few druggists, even in so large a city as Baltimore, keep a supply of the drug on hand, it occurred to me that physicians were neglecting a valuable remedy, and that it would perhaps not be amiss were I to call the attention of this Society to its value as a therapeutic agent in this class of cases.

Eserine is an alkaloid obtained first by Vée and Levan, in 1865, from the now well-known calabar bean (*physostigma venenosum*). It can be had in the form of the alkaloid, the sulphate, or the salicylate. The best-known physiological effect is the marked contraction of the pupil following the instillation even of very dilute solutions into the eye. It was in 1875 that the anti-glaucomatous effect of eserine was first discovered by Professor Laqueur, of Strasburg, and its very greatest value is in this terrible disease.

That eserine has the power of lessening intra-ocular tension has been demonstrated by many observers. In ulceration of the cornea the worst symptom is the photophobia, and the greatest danger is rupture of the eyeball from intra-ocular pressure. We thus have an agent which, while it contracts the pupil, and shuts out much of the annoying light, at the same time lessens pressure and the danger of rupture, keeping the eye in the best condition for the reparative process, and the patient in the most comfortable situation possible during this time. Thus, theoretically, eserine should be a valuable agent in corneal ulceration, and I think the cases reported below bear me out in thestatement that it really is.

There is one variety of corneal ulcer to which I have found it particularly adapted, namely, that following a blow from a piece of an oyster-shell, described first, I believe, by Dr. W. J. McDowell in 1879, under the name of "oyster-shucker's corneitis." My experience, however, extending over the last seven years, differs from that of Dr. McDowell in several particulars. First, he lays especial stress on the central location of the lesion, which he refers to as a "pearly opacity of interstitial exudation, appearing always near the centre of the cornea." The etiology he considers "a specific toxic element contained in the slime and dirt which coats the oyster shell," which, getting into the eye, starts the trouble; for, says he, "no trace of traumatism can, by the closest scrutiny, be detected." My notes of cases show that the spots occur anywhere on the surface of the cornea, often there is evidence of traumatism, and I have many times removed small pieces of shell. Still, in most cases, there is no break in the smooth corneal surface. For the first few days there is merely the perfectly circular white spot, accompanied by photophobia and congestion of the scleral zone of blood-vessels. A few such cases go on to get well with simple treatment and without complications. The majority do not, and after several days the opacity is very white and looks much like a foreign body. If any attempt be made to remove it as such, it will be found to be a slough of the outer layer of corneal tissue, free at the edges, and only attached at the very bottom. A day or two later this slough comes away, leaving an ulcer with sharply cut edges of about the size of the head of a large pin. Until I began to use eserine I found these ulcers often very intractable, entailing on the patient, in most instances, several weeks of suffering.

From my note-book I subjoin hasty notes of eighteen cases. These cases were all seen at the Presbyterian Eye, Ear, and Throat Charity Hospital, and a number were seen but once. These latter are only mentioned here to substantiate the statement above, that the ulcers from injuries by oyster-shells may occur anywhere on the cornea, and, of course, contribute little to our knowledge of the effect of treatment by eserine—though the presumption is that they did well, as those of us having experience with dispensary practice know that, as a rule, these people keep coming till they no longer suffer, and are able to return to work; and again, on the other hand, as soon as this is the case, they return to work and are seen no more. Of course there are exceptions to this; but, as a rule, when we lose sight of one of these patients after one or two visits, it is because there is no longer urgent necessity for treatment.

I have made no selection of cases, and those mentioned are all of this class, which came under my care between October 5 and October 29, 1887.

Case I.—W. H. J——, aged twenty-eight, came to me, October 5th, with the history of having been struck in the left eye three days previously with a piece of oyster-shell. Examination showed the usual scleral congestion, accompanying a small corneal ulcer, which was located near the inner border of the cornea. Another physician had put some "drops" in the eye the day before, presumably atropine, as the pupil was partially dilated. Since the use of these drops patient had found the light more painful. Eserine sulphate, gr. j. to ℥ j., was ordered to be dropped into the eye three times a day.

October 6th.—Congestion less; eye less painful, and stands light better.

October 8th.—Patient says eye "eases off," *i.e.*, sometimes better and sometimes not so well. The ulcer is much better. Patient did not again return.

Case II.—C. B——, aged twenty-five, October 5th. Patient reported having been struck in the left eye two days previously by shell while shucking oysters. Had ulcer, one line in diameter, at lower border of cornea. There was much congestion and photophobia, though he said the eye was then better than it had been the previous day. Eserine sulphate, gr. j. to ℥ j., was ordered, and patient was seen no more.

Case III.—J. B——, aged eighteen, applied for treatment October 6th. He had been struck in the left eye two weeks previously with an oyster-shell. Examination hsowed a central superficial corneal ulcer, and some pus in the anterior chamber. Much pain was felt on exposure to light, and there was the usual amount of congestion. A light-pressure bandage was applied, and eserine ordered to be used three times a day.

On October 7th the light was still annoying, but the ulcer was better, and there was only a trace of pus in the chamber.

October 8th.—Eye better in every way; very little pain on exposure to light, and the pus had entirely disappeared.

Case IV.—S. S——, aged forty-seven, struck in right eye three days before with oyster-shell. Large corneal abrasion, and small, central, deep ulcer; vision dim, but very little irritation or photophobia. Eserine was ordered, and patient seen no more.

Case V.—C. S——, aged sixty-eight. This patient had been under observation for about two years. During this time she had been suffering with granular lids, and had, as usual, been treated with nearly all the astringents and a number of the caustics, with the result of keeping her in fairly comfortable condition, until about three weeks previous to the time to which these notes refer. Her corneæ had always remained clear. About September 29th the corneæ were still all right, but when next seen, October 5th, a large ulcer, crescent-shaped, about two and a half lines long by a line broad, was seen at the upper border of the right cornea. Light was very painful, and there was a good deal of muco-purulent discharge from the eye. I have no note of the treatment used on this day.

On the next, October 6th, and from that time, eserine was used once a day on the occasion of her visits to the dispensary, and a solution of borax was given, to be used four or five times a day at home.

---

[1] Read before the Baltimore Academy of Medicine, May 1, 1888.

October 8th.—Eye was less painful, and there was less irritation about the ulcer.

October 10th.—Condition same.

October 19th.—Eye much better; ulcer healing, and congestion and photophobia much less.

October 24th.—Ulcer healed, and eyes in same condition as before formation of ulcer. This was a remarkably favorable termination, when the constant irritation from the granular lids is taken into consideration.

Case VI.—A. S——, male, aged thirty-three. October 8th: This patient was struck in right eye the day before with piece of oyster-shell, and on examination presented a small, corneal ulcer, one line from the upper margin of the cornea. Light painful, and movements of eyeball gave pain. Eserine sulph., gr. j. to ℥ j., was ordered.

Case VII.—A. L——, male, aged twenty-two, was struck with piece of oyster-shell on October 7th, and on the 10th, when he came for treatment had a small, deep ulcer below the centre of the left cornea. Eserine sulphate was used, along with borax solution, and on the 13th the patient expressed himself as a "great deal better." Light was no longer painful, and the congestion was much less; ulcer healing rapidly; treatment continued.

Case VIII.—J. M——, male, aged twenty-seven. October 10th: Struck in left eye two days previously with piece of bone. Examination showed a narrow cut of cornea, one line from the upper margin; much congestion; light painful. Cornea was not perforated. Eserine was ordered to be used three times a day.

On the 14th the eye was much better. Pupil was closely contracted, and there was little or no pain.

Case IX.—P. G——, male, aged sixty-five, came under observation October 10th, his left eye having been sore eight or ten days. He had a superficial ulcer of upper and outer margin of cornea. There was not very much congestion. Eserine sulphate, gr. j. to ℥ j., was ordered to be used three times a day.

October 13th.—Light was still painful, and there was no change in size of ulcer, which had rather more the appearance of an abrasion. The pupil was closely contracted. Atropia was now used once, and pupil dilating under it, the eserine was continued at home.

October 15th.—Eye no better. Eserine was discontinued, and atropia was used at hospital and borax at home.

October 17th.—Eye in same condition. Pupil not dilated, and atropia was ordered to be used three times a day.

On the 18th the eye was more congested, and the corneal abrasion a little larger. Yellow oxide of mercury ointment was ordered, and the patient was seen no more till the 24th, when he came with the statement that he had been under the care of another oculist, and was using "drops" ordered by him. There was no change in the condition of the eye. Calomel powder was now dusted into the eye, and the "drops," which were found to be atropia, continued at home.

On October 27th the eye was no better, and I returned to the use of eserine, and from this time the patient was lost sight of. This is the only case of the series where eserine did not prove of positive benefit.

Case X.—M. H——, colored, male, aged thirty-two. October 12th: Patient was struck in right eye two days before by piece of oyster-shell; eye painful since the injury; much ciliary congestion; small spot of infiltration near the border of cornea. Eserine, gr. j. to ℥ j., was used, and on October 14th there was only small opacity left. No pain or redness, and patient was dismissed as cured.

Case XI.—D. M——, male, aged fifty-six, came for treatment October 14th. He reported that the right eye had been sore about five days, and was very painful, especially in the morning. He had an ulcer one line in diameter below the centre of the right cornea. The light was not painful except in the morning. Eserine was used at this visit, and patient was given borax drops to use at home, and he did not report for further treatment.

Case XII.—J. B——, male, aged thirty-six, was struck with oyster-shell four days before applying for treatment. He had an ulcer at outer margin of cornea, but not much congestion or photophobia. He said that the eye had been worse a few days before than at the time of his visit. He was ordered eserine sulphate, gr. j. to ℥ j., to be used three times a day, and did not again report.

Case XIII.—William T——, aged forty-three. Four days previous to applying for treatment, was struck in right eye with oyster-shell. He had central corneal ulcer, much congestion, and previous night the light was very painful. There was some pus in the anterior chamber. Eserine was ordered to be used every three hours.

Case XIV.—Noah B——, aged twenty-six, was struck by piece of shell in left eye, one week previous to date of his visit on October 16th. He had an ulcer in centre of cornea, one line in diameter; much congestion, but very little pain. Eserine, t.i.d.

October 17th.—He expressed himself as a "heap better;" pupil closely contracted, and still a good deal of congestion.

On the 18th he reported that the eye had been painful that morning. There was more congestion than on the previous day; pupil contracted, and ulcer plainly healing. I then used a single drop of atropia solution, and after a few minutes, under partial dilatation, the eye became painful.

Case XV.—Mr. McM——, thirty-five years of age, seen first time October 17th. His left eye had been sore ten days, and examination showed several superficial corneal ulcers. Eserine was used at hospital, and borax solution at home.

October 18th.—Pupil not contracted. Effects of eserine having passed off, eserine was again used once, and on the 19th eye was doing well, and patient said that it was much better after I put in the drops yesterday, *i.e.*, better after application of eserine.

October 22d.—Eye doing well, ulcers nearly healed. "Sees better, but is not sure that eye is so strong."

October 24th.—Eye much better, and patient is anxious to return to work.

November 1st.—Vision, a little dim from slight opacity of cornea, very little congestion, and patient was dismissed.

Case XVI.—William F. M——, aged thirty-eight, on October 17th and 18th was seen at the hospital by one of the other surgeons, and during this time was treated with a solution of borax.

On the 19th, when I saw him, he stated that his left eye had been sore three weeks, the conjunctiva was congested, and the upper border of the cornea was vascular, and at the inner border was a narrow ulcer. The light was annoying rather than painful. Eserine was instilled, and ordered for use at home. The next day he said that the eye had pained very much after the use of the drops the previous day. Since that time it had been more comfortable. The pupil was closely contracted, and the light less annoying.

Case XVII.—Mrs. D——, aged sixty-four. When first seen, October 29th, her left eye had been sore one week. She had a narrow, deep ulcer at the upper and inner quadrant. There was much congestion. A haziness of the pupils was also observed, which the ophthalmoscope showed to be incipient cataract in both eyes. Eserine sulphate, gr. j. to ℥ j., was ordered.

October 31st.—The eye was in the same condition, but the pupil was closely contracted.

November 1st.—The eye was much better, though, on account of the contracted pupil the vision was worse. Ulcer healing rapidly.

November 2d.—Ulcer was nearly well, and I discontinued the eserine on account of the dim vision produced by the contracted pupil in the cataractous eye.

Case XVIII.—William B——, aged forty-five, got a piece of oyster-shell in the right eye, October 28th, and on the 29th came for treatment, having a small central corneal ulcer, and much congestion of the eye, with intolerance of light; otherwise, not much pain. Eserine was ordered, and the patient did not again report.

To summarize briefly: Of the eighteen cases ten were surely and positively benefited, being under observation several days. Seven were seen but once, and from this fact it is a fair presumption that most of them required no further treatment.

One case only did not seem to be benefited. This patient was under observation for seventeen days, and during this time various remedies were used without avail. On his last visit he was directed to return to the use of the eserine. His case was not from injury by oyster-shell.

Finally, in the use of eserine two cautions are to be observed: First, not to make the solutions too strong. With many patients a solution stronger than gr. j. to ℥ j. gives a great deal of pain; and, second, to be very sure that the case you are treating is not complicated by iritis.

SUPPURATIVE PERITONITIS AND PLEURITIS FOLLOWING PARTURITION; DRAINAGE AND RECOVERY.

By W. FRANKLIN CHAPPELL, M.D., M.R.C.S.,

ENGLAND.

The following case was treated by me, some years ago, in London, and is now brought forward on account of the interest attached to cases of this kind:

January 28, 1884, I attended Mrs. M——, aged twenty-three, in her second confinement, with a healthy child. The labor was natural and the patient progressed favorably until the morning of the fourth day, when she was seized with a violent chill, which lasted twenty minutes, followed by free perspiration.

Three hours later the bowels were freely relieved and she complained of slight abdominal pain and tenderness. Uterus enlarged as compared with previous day. Temperature, 102°; pulse, 120; milk decreasing; lochia normal; tongue moist.

February 2d.—Temperature, 102°; pulse, 130; tongue sore at edges. Diarrhœa set in during the night, stools frequent and copious, dirty green in color, and very offensive; lochia decreased and offensive.

Complained of severe pain in right thoracic region, increased by inspiration, and of tenderness over the abdomen. Auscultation detected a friction sound over lower part of right thorax; percussion, slight dulness; pupils dilated; pale, anxious expression, with short and frequent respiration.

February 3d.—Temperature, 103°; pulse, 130; pupils widely dilated; eyes sunken. The pinched, anxious expression and diarrhœa continued. Vomiting everything taken into the stomach. Uterus more enlarged and tender. Thoracic dulness increased. Abdomen slightly enlarged.

February 4th.—General symptoms continue the same. Small patches of crepitation over the upper part of right lung, with cough.

February 5th.—Diarrhœa ceased. Mouth and tongue covered with small curd-like masses. Complains of feeling of oppression in the chest.

February 6th.—Mouth, tongue, and fauces very red, complains of their feeling very sore and dry, and has a great desire for cold fluids.

Patient remained in about the same condition until February 10th, when the temperature went up to 104°, and she complained of chilly sensations during the day, with perspirations at night. Diarrhœa returned and lasted twelve hours.

On the 15th she had a severe rigor, followed by extreme prostration and difficulty in respiration.

During the next four days the urgent symptoms subsided; other general condition improved.

On the 20th she had another severe rigor, followed, like the previous one, by great prostration. The apex-beat at this time was three inches to the left of left nipple, and there was complete dulness over right side of thorax. Abdomen very much distended, respiration 60 per minute, cough troublesome, expectoration *nil*. Patient very much emaciated, but perfectly conscious throughout the illness. Dr. Stephen Mackenzie, of the London Hospital, and Dr. Edmund K. Howchin, now saw her in consultation with me. We decided to draw off the fluid in the pleural cavity.

After administering brandy I introduced the needle of the aspirator near the angle of the scapula between the sixth and seventh ribs, and evacuated two quarts of thick, purulent fluid. The patient then fainted and the operation was discontinued.

The following day I put a trocar into the abdomen, and drew off six quarts of pus. The patient immediately expressed herself as feeling much better, and the temperature fell in twelve hours to 101°; respiration, 30; and all urgent symptoms subsided. This favorable condition continued for a few days, then the abdomen and thorax began to refill, rigor returned, and, in fact, a general recurrence of all the previous urgent symptoms. I now decided that a free opening into both cavities was the only hope for my patient, and for that end introduced a drainage-tube into the pleural cavity at the point where the aspirator had been introduced, also one in the median line into the lower part of the abdomen.

The wounds and openings of the tubes were kept as antiseptic as possible. The patient improved immediately. The discharge from the tubes grew less each day, and on March 10th I removed the tube from the abdomen, and on the 14th the one in the pleural cavity.

On the 15th the abdominal opening was healed, and on the 17th that in the pleura. In neither cavity was the washing-out process employed.

The patient was still very weak and emaciated, and some two months was passed before she was able to resume her usual duties.

I saw her one year after this illness; she expressed herself as being perfectly well. On examination of the chest, I found the right side flattened and some loss of expansion, and a thickened pleura, otherwise, as she said, in perfect health.

I have not given the medical treatment of the case, as it would unnecessarily lengthen the description. I treated the various symptoms as they arose, and gave the usual supporting remedies and nourishments, and disinfectant vaginal injections.

22 East Forty-second Street.

Strange, if True.—A curious case is reported in the Savannah *News* of a gentleman living in Atlanta. One of his eyes is dark blue in color, and the other is a light gray. In the daytime—from sunrise to sunset—he cannot see anything out of the blue eye, but sees distinctly and well with the gray eye; and from sunset to sunrise he cannot see anything with the gray one. His hearing is similarly affected. He can hear only on the blind side; thus he can hear with one ear during the daytime, and with the other ear during the night. He never discovered this until recently.—*Sanitary Era.*

Pulmonary Hysteria.—M. Petit reported, at a meeting of the Société de Médecine Pratique of April 5th, the case of a young woman who presented all the general symptoms of pulmonary phthisis, such as hæmoptysis, cough, hectic fever, etc. The physical signs consisted simply in the presence of a few mucous râles. Later the woman presented evident hysterical symptoms, and soon after the menstrual function was restored and the symptoms pointing to pulmonary phthisis entirely disappeared.

Progress of Medical Science.

The Mode of Entrance of Micro-organisms into Wounds.—In his interesting series of lectures on "Suppuration and Septic Diseases," Dr. Watson Cheyne (*The British Medical Journal*) alludes to this important subject as follows: As regards the entrance of these organisms into wounds, they may get in, during an operation, from the air, from the instruments and hands of the operator or his assistants, from surrounding objects, or from the skin in the neighborhood of the wound. We are now, however, sufficiently acquainted with the various precautions necessary to prevent the entrance of these organisms, and it is a comparatively easy matter to leave a wound made through a previously unbroken skin without any pyogenic organisms in it. In the after-treatment of wounds there are two situations where the battle with these parasites may take place; it may either occur outside the wound, the organisms never being allowed to enter it, or it may take place inside the wound after their entrance has been permitted. It is hardly necessary to remark that in case of war we try, if possible, to carry the war into the enemy's country; at all events, we do all we can, by guarding the passes and borders, to prevent the enemy from entering our own country; and in like manner, in the case of wounds, it seems to me that it is much better to keep these pyogenic organisms out of the wound and to do battle with them outside the body, than to let them enter and trust to the efficacy of the tissues to repel their attacks. For, once they have entered the wound, it is but little that we can do to aid the action of the body, and what little we do do has to be done with extreme cautions, for not uncommonly our efforts, instead of being of service, do a great deal of harm. As I have said, it is comparatively easy now to keep these pyogenic organisms out of a wound while it is being made, and to leave the wounds without any of these microbes in it; the problem is to prevent their entrance afterward. In this case, however, we have at any rate succeeded in transferring the field of battle from the interior of the wound to the surface of the body, and we have no longer to trust to the imperfect and but little understood action of the tissues; we can step in with vigorous action without any fear of doing harm. For it cannot be too much insisted on that antiseptic dressings are not, in their essence, applications to wounds; they are applications to the discharge which has come from the wound and to the skin around it. As to the mode of entrance of these pyogenic organisms after the operation, they may get in while the dressing is being changed, either by falling in from the air, though this must be of rare occurrence seeing that they are so rarely present in the air, or by contamination by the surgeon's hands, instruments, etc.; but this is also very easily avoided, and ought not to occur. Usually they spread in either through the dressing or beneath it during the interval between the change of dressings. In my opinion they most commonly spread in by growing in the discharge which is lying between the dressing and the skin, and in the superficial layers of the epidermis, more especially in the latter; for, as the result of the irritation of the antiseptic employed, there is hypertrophy of the epithelium, and thus a large number of dead epithelial cells are present, which, being soaked with the discharge, form a good nidus for the development of the bacteria, unless, indeed, enough of the antiseptic has been communicated to the discharge and the epithelium from the dressing to render it an unsuitable soil for the growth of organisms. If this is not the case, the organisms will go on growing in the substance of this dead epithelium, protected by the superficial layers from the action of the dressing, and thus they may, if a dressing is left on for too long a time, ultimately reach the wound. This is not a mere theoretical speculation, for I have been able to trace the development of the organisms beneath the dressings, from their margin toward the wound, the extent to which they spread varying with the length of time that the dressing has been applied. If these views as to the mode of entrance of bacteria into wounds are correct, it follows that it is very important when a dressing is changed to wash and thoroughly disinfect the skin around the wound as far as the dressing extended, and beyond it, with an antiseptic lotion, care being of course taken by covering up the wound not to infect it while so doing. If this is done, then at each change of dressing the field of battle is transferred from the neighborhood of the wound to the margin of the dressing, and in accordance with the size of the dressing this battlefield will be at a greater or less distance from the wound. We have now at our command a large number of antiseptics which more or less answer the purposes required, and it is only by careful attention to the exclusion of these organisms that we can obtain the best results. That we can completely exclude these bacteria from wounds—both at the operation and afterward—I have been able to ascertain by numerous experiments; and that, just in proportion as we are successful in so doing, we are to a like degree freed from the occurrence of suppuration and septic diseases, and can to a like degree reckon with confidence on rapid and painless healing of wounds with the least disturbance to the patient, is a matter now of every-day observation.

Oxygen as a Heart Food.—Under the title of "Heart Foods" Dr. L. C. Winsor speaks as follows concerning the utility of oxygen: It is a fact that tissue will absorb oxygen, and give off carbonic acid without the intervention of the circulation, and so we may believe that the appropriation of oxygen is due simply to the demand of the cells, and not to any peculiar form of the oxygen, or any combination of it in the blood. The sluggish circulation of the blood in organic heart disease does not supply sufficient oxygen to the body, and hence the symptoms—dyspnœa, headache, fainting spells, debility, etc.—which arise. The rational method of diet should not only include proper foods, but also an increased supply of oxygen. We can see no objection to classing oxygen as a food, and placing it pre-eminently as such. (It may be classed as a fuel food, but as a tissue food it has no equal.) It is the basis of all tissue building. An increased supply of oxygen rather than a stimulated circulation, a saturating of the blood with oxygen rather than an increased supply of poorly oxygenated blood, is the ultimatum of diet in heart diseases. The effect of this plan of diet will be to increase the supply of readily digestible tissue food, and to furnish an abundance of oxygen, the agent which of all is the most valuable for tissue building. This done, there will be but little left for drugs to accomplish. As to the administration of oxygen, it has become so well known, and the methods for administering it so improved, that it is at the command of every physician.—*The Dietetic Gazette*, April, 1888.

The Pathology of Icterus Neonatorum.—From a careful study of this subject, Dr. Liebermann has arrived at the following conclusions: 1. Icterus neonatorum is a reabsorption icterus, and therefore of hepatic origin. 2. The detention of the bile takes place in the intercellular gall-ducts and the interlobular gall-ducts, which are compressed by the distention of the arterioles and capillary blood-vessels within the liver. 3. This congestion is accomplished by an alteration of the blood circulation in the liver immediately after the birth of the child, which apparently is partially due to a complete change in the blood plasma. 4. This blood change is accompanied by a "fermentæmia." 5. The icterus is greater the weaker the new-born child is. 6. From the great number of red blood-corpuscles that are destroyed a rich store of material is prepared for the formation of bile pigment, and this material, coming under the action of the fermentæmia, produces a slowing and finally an engorgement of the hepatic blood-vessels.—*Archiv für Kinderheilkunde.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 23, 1888.

THE DIGESTION OF FATS.

SEVERAL years ago Dr. Dastre, of Paris, demonstrated that the presence of bile in the stomach did not disturb gastric digestion, and that it did not result in the precipitation of peptones, such as is seen in test-tube experiments. He claimed that it was a mistake to suppose, as some physicians and physiologists still do, that the entrance of bile into the stomach could produce vomiting or result in grave gastric disturbances. These facts were established by him by the artificial introduction of bile into the stomachs of dogs at various periods during the process of digestion. The method employed was either that of œsophageal introduction by the sound, or by establishing a gastric fistula. His assertions were confirmed by the elaborate researches of R. Oddi and Marcocci (of Sienna).

On July 16, 1887, Dr. Dastre exhibited before the Paris Society of Biology two dogs, in whom he had established a cholecysto-intestinal fistula. This operation had succeeded in deflecting the flow of bile from its natural direction, and allowing it to escape into the middle of the small intestine (jejunum), in place of the duodenum. In order to accomplish this result, he had removed by operation a sufficient piece of the bile duct, and then attached the gall-bladder directly to an opening made in the intestinal wall.

The establishment of fistulæ of this kind enabled him to study the problems of the digestion of fats and fatty substances, not outside of the body (as has been hitherto generally done by others), but within the living organism.

It is well known that since the investigations of Claude Bernard the digestion of fats has been attributed to the action of the pancreatic juice, rather than to that of the bile. In test-tube experiments, it is true, the pancreatic juice is capable of emulsifying and digesting this class of substances. Among living animals the rabbit furnishes an example which might be construed as a natural argument in favor of the same view; for in this animal it is found that the pancreatic duct opens into the intestine about fifteen inches lower down than the bile-duct. In the intervening space the ingested food, having left the stomach, is acted upon solely by the bile. If now some fatty matter be mixed with the food, it is easy to see (as Claude Bernard pointed out) that in this space the fats do not become emulsified, and are not digested. It appears that the fat-carrying lacteals do not assume the characteristic milky look before the pancreatic secretion has had an opportunity to act, namely, lower down in the course of the intestine.

It follows from Dr. Dastre's experiments on the dog, that this animal may furnish the opposite condition of that which has been described in the rabbit. That is to say, in the dog, after a successful operation, the bile-duct opens into the intestine much lower down than does the pancreatic duct. Consequently it so happens that, for this entire length, the fatty substances come in contact only with the pancreatic secretion.

This artificial arrangement in the dog offers the following advantages: In the first place, the field of observation is a more extended one than in other animals not submitted to operation; and, in the second place, the lacteals of the dog represent the best and most distinct type of these vessels.

In order to assure himself that dogs operated upon in the way described did not suffer from impaired digestion, he observed two animals with these fistulæ for four months, and found them to remain in perfect health.

These two animals were supplied with a copious meal, consisting of meat, fat, and milk. They were then killed during the process of most active digestion. An examination now showed, with remarkable distinctness, that the lacteals were quite transparent between the stomach and the fistula. That is to say, there had occurred no notable absorption of fat in that portion of the alimentary canal in which the pancreatic juice alone had acted. On the other hand, a few inches below the fistula, and after the intervention of the bile, the lacteals were found to be quite milky and opaque. The interpretation of these positive facts permits but a single doubt. It might be feared that the observation was made too slowly. In that case the network of lacteals first alluded to as being found empty would prove, not that no absorption had occurred, but rather that it had already terminated. Dr. Dastre believes that he has met this possible objection by assuring himself that, in these two animals, the stomach as well as the first part of the intestine still contained some of the ingested food.

It follows, therefore, that if our observations on the rabbit teach us that the bile alone, in the living animal, is impotent to effect the perfect digestion and absorption of fats, so, too, experiments on the dog demonstrate that the pancreatic juice alone is equally impotent to effect such a result. A mixture of these two secretions is quite indispensable. The bile is just as necessary as the pancreatic juice for the digestion of fatty substances.

Certain experience with regard to the total suppression of bile or the pancreatic juice, permits us to assign a more exact rôle to each of these secretions. Thus it would appear that the bile is intended more particularly to facilitate the absorption of fats in their natural state, whereas the pancreatic juice fulfils the office of splitting up compound fats into simpler bodies.

The stools of animals in which the bile is prevented from being poured out into the alimentary canal are found to contain forty or more per cent. of undigested fats (100 representing the total amount of fats ingested). In the normal condition of affairs, according to the researches of Bidder and Schmidt and Voit, scarcely one per cent. of the fats is evacuated unchanged. Analogous results are obtained in cases of complete suppression of the pancreatic secretion. That is to say, the absorption of fats is not altogether checked, but it is always considerably diminished.

The following observation will make this matter clear. A dog, having a biliary fistula, receives into his stomach a large quantity of fatty substances. Three hours later the animal is killed. An examination now shows the following condition of things: From the duodenum to about the middle of the large intestine the lacteals are turgescent with a milky fluid.

Nevertheless, this evidence of fatty absorption differs in several particulars from what is seen in the normal state during active digestion: 1. The receptaculum chyli is filled with a thickish-white substance, under the conditions above alluded to. This milky material appears to consist largely of fatty acids. 2. The lacteals appear tense, filiform in shape, and are found filled with the same whitish substance just mentioned. 3. The rare sight is seen, with remarkable distinctness, of nodosities or bulging pouches along the course of the lacteal vessels. These pouches occur at a distance from one another of about half an inch. They correspond to the valves of the chyliferous vessels. Their marked distention goes to prove with what difficulty this particular fatty substance circulates within those vessels.

These interesting observations by Dastre will go far toward elucidating a hitherto obscure chapter in human physiology. Whether the data furnished by this industrious French observer can be utilized so as to supply a basis for a more rational treatment of hepatic and pancreatic affections remains to be seen.

ALCOHOLIC AUTOMATISM.

MOST persons when intoxicated are maudlin, silly, quarrelsome, or brutal, more or less in accordance with their dominating natural instincts. They are rightly held responsible for their acts.

There are cases, however, in which small amounts of liquor send the person at once into a truly abnormal mental state. They are not drunk, but insane. They are known as cases of periodical inebriety and alcoholic automatism. The law does not yet recognize the distinction between the above classes.

An illustration, most probably of alcoholic insanity or automatism, has figured prominently in the city courts during the past week. The man has frequently been mixed up in drunken brawls, in all of which it appears that liquor, in not excessive amounts, produces rapid and extraordinary changes in his mental and moral condition.

MEDICINE AND CIVILIZATION.

A WRITER in the *Medical World* advises physicians to broaden their knowledge by studying sociology, and thinks that it is the tendency of our present civilization to lessen the average compensation of physicians, and to detract from their importance in the community. As one of the grounds for this opinion he refers to the fact that, where our civilization is most fully developed the compensation and social position of physicians are lowest, although in the same localities the standard of qualification which is applied to them is highest. The average compensation of physicians is lower in Germany than in England; lower in England than in the eastern part of the United States; lower in the Eastern States than in the Western.

This sort of reasoning, however, will hardly hold. The compensation of physicians is greater in Germany than in Russia; greater in Russia than in China; greater in China than in Timbuctoo. Physicians, on the average, are paid better, live better, and are more highly esteemed in this nineteenth century than they were in the seventeenth. The world is becoming more critical of medical service, but it pays better than ever for first-class work.

MR. DEPEW ON THE DOCTOR.

MR. CHAUNCEY M. DEPEW is not a believer in rules and maxims for guidance in life. He dropped a phrase, however, in his speech before the Syracuse Medical, College last week, which is likely to be perpetuated. Speaking of the importance to the physician of an agreeable and sympathetic manner, he said: "But when the cheerful and hopeful physician enters the room he brings in comfort and health. The sufferer knows that this man is able and skilful, that his brain and heart are full of the case, that his sympathies follow his efforts, and *the potentiality of his powders is intensified by the inspiring magnetism of his personality*."

We would say to this at once that the periphrasticity of Mr. Depew's eloquence greatly accentuates its aptness and profundity.

Mr. Depew is right about the importance of culture of mind and suavity of manner to the modern physician. He says:

"The rush and worry, the wear and tear, the rapid pace of our American life, irritate our nerves and render us peculiarly sensitive to impressions. The personality of the doctor, his disposition, his habits, and his character form a large part of his success or failure. The vain and pompous doctor who thinks so much of himself that he fails to appreciate the weakness and watchfulness of the sick, leaves behind him a sense of neglect and indifference which neutralizes his medicine. The discursive and argumentative doctor airs his opinions on politics or theology to aching bones and fevered brains until only weakness keeps the outraged victim from murder. The grossest injury to the helpless patient, absorbing with every breath the spirit of her environment, is the polluting presence of the doctor saturated with whiskey or tobacco."

With regard to the success of the doctor's life, Mr. Depew also says some wise things:

"I have no faith in mottoes, or maxims, or rule for success, and, though often asked, never have any to give. A young man who has good health and governs his conduct by a conscientious answer to the ever-present question, Would my mother approve? and gives tireless attention to his business, is certain to succeed. It is impossible for everyone to win fame or fortune, or both; but the man who earns a living, even in a very modest way, feels the inspiration of independence, and has safely passed the precipice of failure. Repinings for riches and angry envy of prosperity weaken the moral tone and mental fibre. They paralyze effort, and end in empty vaporings in the bar-room and empty larders at home. The opportunities for accumulating large fortunes rarely come to members of the liberal professions. Their compensations are in the position and influence accorded to their culture and training. With them self-support is success, and when the surplus surely comes, and with it home, larger comforts, and fair competence for declining years, they enjoy a measure of happiness and content rarely found with the use and care of great wealth."

We feel sure that Mr. Depew would have made a good and successful doctor, if he had not chosen a narrower field of usefulness in attending to the sordid details of railroad transportation.

JEFFERSON MEDICAL COLLEGE AND EDUCATIONAL PROGRESS.

It must be with some feeling of mortification that the New York physician hears again of the laggardness of his medical colleges in advancing the study of medicine. For years Harvard and the University of Pennsylvania have required a three years' course; now we learn that Jefferson Medical College has made a similar step in advance. Philadelphia's two oldest and largest colleges have thus put themselves in the van of educational progress. It is a state of affairs worthy of Philadelphia's reputation as a great medical centre.

Meanwhile, in this city efforts to carry out the same reform remain futile. Even our most richly endowed college, with a number of students so large as to strain the capacity of any single faculty successfully to teach them, fails to make the advance which the modern sentiment of the profession demands.

THE HOSPITAL AS A NUISANCE.

The question whether a hospital placed among private residences is a nuisance has recently been raised in the courts. An attempt was made last fall to establish a Babies' Hospital on Lexington Avenue, a street occupied entirely by private residences. An injunction was obtained on the ground that the proximity of the hospital to the private dwellings made it a danger and a nuisance.

Judge Beach, of the Supreme Court, granted the application for injunction, giving the following as his reasons:

"The hospital is not a nuisance *prima facie*. While not within that class, there are, nevertheless, general features inseparable from its maintenance proper for consideration, upon the contention of its being shown to be a nuisance from the way of mismanagement. In these are included noise of patients, their advent, removal, and death with its consequences. From evidence it appears that there is a reasonable probability of contagious diseases, provided for with a wise provision, although limited to cases which develop after reception. This makes an important factor. The locality was wholly devoted to private residences until the laudable undertaking selected the home for its accomplishment. To my mind, the hospital is not a reasonable use of property upon a consideration of the surrounding circumstances. The care of children in numbers brings danger to the youthful members of families living near. Then, too, this site was selected with full notice from a restrictive covenant in the deed. That, too, I think fatal to the defendant. I am inclined to think that there was an error on trial in excluding proof claimed to show a depreciating effect upon surrounding property. The court has invariably enforced such covenants, save when the character of the contiguous property was wholly changed in use from the original design. The hospital, even if not dangerous, injurious, and offensive in the same way as a tenement house, livery or other stable, still shows a similitude in the nature of the injury or offence, if not in the particular manner stated in the conveyance."

An appeal will be made from this decision.

THE NEW YORK ACADEMY OF MEDICINE AND MEDICAL SOCIETY ORGANIZATION.

At a recent meeting of the Chicago Medical Society, the retiring President, Dr. W. T. Belfield, urged that that Society imitate the plan of organization employed by the New York Academy of Medicine, viz., of having special sections organized for each subdivision of medical science.

This plan is spoken of as highly successful.

We feel disposed to caution our Chicago brethren against precipitate action in the matter. The plan adopted by the New York Academy is theoretically excellent, and has been in some respects admirably successful. We learn, however, that there is a feeling that subdivision has been carried too far, with the result of increasing excessively in this city the number of medical societies (thirty-four or five in all), and making too great demands upon the physician's time.

It is unquestionably true that the attendance at some of the Sections of the Academy has been very small, while the labors of the executive officers have been very great. The result of the experience of the past two or three years has, we venture to say, led to a decided feeling that the frequency of many of the section meetings should be lessened, and perhaps the number of the Sections be made smaller. The section method is not a failure, quite the reverse; but it needs important modifications. It would probably be more successful in cities which have not already a number of well-organized private, special, and general societies.

THE MODERN ANTIPYRETICS.

The antipyretics which have fallen into disuse after a good deal of temporary "booming" are now quite numerous. Some, while no longer employed in fevers, have found a field of usefulness elsewhere. One of the pioneer antipyretics was the tartrate of chinoline, which was synthetically made by Königs in 1880, and used as an antipyretic by Baeyer, Skraup, and others.

At about the same time Lichtheim, of Berne, showed that resorcin was an active antipyretic, resembling in many respects salicylic acid.

The first of the pure antipyretics was kairin, a substance prepared in 1882 by Drs. O. Fischer and W. Königs, and tested physiologically and clinically by Filehne. This drug, like antipyrine, was patented, and then advertised and extolled on true business principles. After considerable use it had to yield to more powerful successors.

Among them was thallin, a chinoline derivative, discovered by Dr. Skraup in 1884, and known chemically as sulphate of tetrahydropara-chinanisol. It was shown to be a very certain antipyretic, with the especial advantage, as claimed by some, of being rapidly eliminated from the system.

Antifebrine (acetanilide), discovered by Gerhardt in 1853, was found to be an active antipyretic by Professor Kussmaul in 1886.

Salol, a compound of about sixty per cent. salicylic acid and forty per cent. phenol, is a patented preparation, first recommended by Sahli in 1886, and since then industriously advertised. It has more reputation as an antirheumatic than as an antipyretic.

Antithermin, or phenyl hydrazinlevulic acid, discovered by Nicot, and acetyl-amido-phenol, are two new antipyretics of which as yet little is known.

Benzanilide is a substance much like antifebrine in its physiological and therapeutical effects. It has been tried and recommended by Cahn and Hepp.

The last candidate for antipyretic favor is phenacetine, a drug recently described in these columns. It has been used in this city with some success.

We have not made any mention of antipyrine, preferring to end our account of the antipyretics with a description of the way in which this remarkable drug has been handled by the business and medical gentlemen who put it on the market. The story is from Dr. Squibb's "Note on Antipyretics," in his *Ephemeris* of June, an article upon which we have drawn largely for the history above given of the other antipyretics.

"In the early part of 1884," says Dr. Squibb, "Dr. L. Knorr, of Erlangen, synthetically prepared an oxygenated alkaloid which he called antipyrine. This was investigated therapeutically by Professor Filehne, who reported that it was an active antipyretic. For some months nothing was published in regard to the character or composition of this substance, but when it had been patented and introduced into commerce by the color-makers above mentioned, Dr. Knorr published a paper stating that antipyrine was a derivative of a hypothetical base which he called chinizin, the systematic name being dimethyloxychinizin. Its antipyretic action was soon reported upon very favorably by many German observers of note, and it was made on a large scale and well advertised at a high price, but not so high as kairin. As it came into use the makers sought to patent it in other countries, and found no difficulty in extending the German patent to the United States. But in France there was difficulty. In the political economy of France, and to the great honor of the nation, it has long been held that the interests of suffering humanity are superior to the interests of inventors, and therefore, as a sanitary measure, patents upon medicines are not granted, and patented medicines from all sources are prohibited. The German patentees were part owners in a color-making company in France, and through this connection obtained a patent on the process for manufacturing dimethyloxychinizin as an aniline product. But as it was not used for any industrial purposes, and could not be sold as a patent medicine, the French patent could not be used; and as processes and articles patented in France but made elsewhere are absolutely prohibited, France seemed to be excluded from the use of antipyrine as well as kairin, unless it be admitted that any chemical manufacturer or pharmacist in France has the legal right to make and sell such articles when used only as medicines, without regard to the patent rights of other nations. This point is understood to be still unsettled, and every parcel of kairin and antipyrine bears on the label, 'Importation into France prohibited on account of the French Patent Laws.'"

Dr. Squibb gives a list of the antipyretic drugs which we have mentioned, with the price per ounce, and the statement as to whether or not it is patented:

Sulphate of quinine (best makers) about	$0 40
Tartrate of chinoline	70
Resorcin	30
Salicylic acid, patented	20
Kairin, patented	2 00
Antipyrine, patented	1 25
Sulphate of thallin, patented	1 75
Antifebrine, 30c. per oz., or as acetanilide	15
Salol, patented	40

News of the Week.

Dartmouth Medical College.—Dr. W. H. Parish, of Philadelphia, will deliver the lectures on obstetrics during the coming session, and Dr. Paul F. Mundé has accepted the invitation of the faculty to give the course on gynecology, the chair of which he resigned a year ago after occupying it for seven years. The late Dr. E. S. Dunster held the chair of obstetrics, and delivered the lectures on gynecology also, during the past year. His recent death has not permitted the faculty as yet to fill the vacancies, which it is expected will be done permanently next year.

The Building Fund of the New York Academy of Medicine.—Dr. Loomis, of the Building Fund Committee of the New York Academy of Medicine, announced at the meeting of the Academy, June 7th, that as a result of the distribution of a few circulars, appealing to the public for aid, nearly twelve thousand dollars had been subscribed. The members were urged to do all they might toward raising, as soon as possible, the further required amount. A portrait of Dr. Van Buren was received from Dr. Keyes, and one of Dr. Jewell, of Chicago, from the New York Neurological Society. Dr. T. Gaillard Thomas read a memorial of Dr. C. R. Agnew, being an eloquent and a warm tribute to one who had resolved in his youth to follow, as nearly as he could, the example of Jesus Christ.

Dr. Rachel L. Bodley, Dean of the Women's Medical College of Pennsylvania for twelve years, died suddenly on Friday of last week at Philadelphia. Dr. Bodley was about sixty years of age. She took a degree in Cincinnati, where she afterward was an instructor. She went to Philadelphia twenty-five years ago, and was for several years a professor in the college of which she became dean.

A Hospital for the treatment of diseases of the throat, nose, and lungs is to be built in Brooklyn.

It is Significant of the progress of American medicine, and of the greater attention which the labors of American physicians excite, that the proceedings of the American Medical Association and other national organizations now receive notice, not only in English and German, but in French periodicals. The Frenchman is the last one to pay attention to anything which occurs outside of his own country.

THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS holds its annual meeting at Washington, D. C., September 18, 19, and 20, 1888. The following programme is announced: The President's Annual Address, William H. Taylor, of Cincinnati. Discussion, Extrauterine Pregnancy. "The Relations of the Abdominal Surgeon to the Obstetrician and Gynecologist," by Dr. Albert Vander Veer; "Operation for an Unusual Case of Subserous Uterine Fibroid," by Dr. Hampton Eugene Hill; "Drainage in Abdominal and Pelvic Surgery," by Dr. Joseph Price; "Double Ovariotomy during Pregnancy; a Successful Case Going on to Full Term," by Dr. William Warren Potter; "The Indications for Artificial Aid in Labor," by Dr. Thomas Opie; "The Technique of Vaginal Hysterectomy," by Dr. James H. Etheridge; "The Surgical Treatment of the Perineum," by Dr. William H. Wathen; "Laparotomy in Peritonitis," by Dr. E. E. Montgomery; "Tumors of the Abdominal Wall," by Dr. Charles A. L. Reed; "Uterine Fibroids; their Diagnosis and Treatment," by Dr. Thomas J. Maxwell; "Desmoid (Fibroid) Tumors of the Abdominal Walls," by Dr. Edward J. Ill; "Ruptured Perineum," by Dr. J. Henry Carstens; "A Contribution to the Study of Pelvic Abscess," by Dr. Clinton Cushing; "The Female Perineum; its Anatomy, Physiological Function, and Methods of Restoration after Injury." This paper will be illustrated with lime-light and screen by Dr. Henry O. Marcy; "Heart Failure in the Puerperium," by Dr. Thomas Lothrop; "Treatment of Suppurative Peritonitis," by Dr. William H. Myers; "Operative Treatment in Uterine Carcinoma," by Dr. George R. Shepard; "The Reflexes Reflected; or, Some Things that Retard Progress in Gynecic Surgery," by Dr. Joseph Eastman; "Some Points in Relation to the Diagnosis of Pregnancy in the Early Months," by Dr. James P. Boyd; "Vaginal Tamponnement in the Treatment of Prolapsed Ovaries," by Dr. W. P. Manton. Mr. Lawson Tait, F.R.C.S.E., Birmingham, England, will also present a paper on "The Methods of Success in Abdominal Surgery."

THE BRITISH MEDICAL ASSOCIATION holds its fifth annual Meeting at Glasgow on August 7th, 8th, 9th, and 10th, under the presidency of Dr. John T. Banks. An address in medicine will be delivered by Thomas Clifford Allbutt, M.D., Consulting Physician, Leeds General Infirmary. An address in surgery will be delivered by Sir George H. B. Macleod, M.D., Surgeon in Ordinary to Her Majesty in Scotland. An address on his "Recent Investigations in Surgery" will be given by William Macewen, M.D., Lecturer on Clinical Surgery, Glasgow Royal Infirmary. An address in Physiology will be delivered by John Gray McKendrick, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.

THE FRENCH HOSPITAL of this city is to be enlarged to double its present size.

A SUCCESSFUL OPERATION FOR PYLORIC STENOSIS.—Loreta's operation, or the digital divulsion of the pylorus for stenosis, with dilatation of the stomach, was performed, June 11th, by Dr. William T. Bull at St. Luke's Hospital. The patient, a man aged thirty-seven, had suffered for twenty months from daily vomiting, pain, acid eructations, and heartburn, and was much reduced in flesh, despite treatment by lavage of the stomach, careful diet, and internal remedies. He was made the subject of thorough investigation by testing chemically the fluids of the stomach, by Dr. F. P. Kinnicutt, and the diagnosis of stenosis from cicatricial contraction of an ulcer arrived at. The operation confirmed the diagnosis, the pyloric orifice being found so small as to admit only a bougie of a diameter of three-sixteenths of an inch. Through a wound two inches long near the pylorus the orifice was stretched gradually with bougies and the fingers till it was over two inches in diameter. No accident followed the operation, and the patient may be now (June 19th) considered out of danger. There has been neither pain nor vomiting, though for several days considerable quantities of liquid diet have been taken by the mouth. A full report of the case will be presented at the October meeting of the Practitioners' Society. This is the first successful case of this operation yet reported in this country.

FREE DOCTORS FOR THE SICK.—It is announced by the Health Department that no sick person need suffer for want of a doctor. In every police precinct there will be a physician ready at all times to minister to the sick, free of charge. By visiting the nearest station-house and presenting the case, a physician will be assigned. Medicine can be procured at any of the city dispensaries on a prescription from a physician of the summer corps.

WALDEYER VERSUS VIRCHOW ON THE NATURE OF CANCER.—Professor Virchow believes that alveolar structure is to be considered as cancer only if the nested cells are found in the mucous tissue itself, and that alveolar structure in the epithelium—that is, above the mucosa—has no malignant character. This, however, is not the opinion of Professor Waldeyer, whose researches on carcinoma are classical. Waldeyer believes that nests of epithelial cells arranged like an onion constitute cancer wherever they are found. Therefore, where Virchow only found "pachydermia laryngis" in the late Emperor of Germany's case, Waldeyer saw cancer. The event proves Waldeyer to have been right and Virchow wrong.

PROFESSOR L. M. POLITZER, of Vienna, well known for his numerous contributions to pædiatrics, died on May 23d, in the seventy-fourth year of his age.

A SECOND CASE OF TRANSPLANTATION OF THE CORNEA OF THE RABBIT to the human eye has been performed, this time in Baltimore. A full and fulsome account of the operation is given in the daily papers.

BICHLORIDE OF METHYLENE is an anæsthetic which Sir Spencer Wells has now used in over two thousand operations. He has never known it to fail, and he has never been alarmed or even made uneasy by its effects, in over two thousand cases in which he has used it.

A CURIOUS WAY TO ADVERTISE AN OBSTETRICIAN.—The following curious items appeared in the *Cincinnati Enquirer*, under the head of Births:

> "FLAMIN.—Saturday, the 9th inst., at 8.15 A.M., to the wife of D W. FLAMIN, of College Hill, a ten-pound boy. Thanks to Dr. Wallingford, of Cincinnati.
>
> "GALLION.—June 5th, to Mrs. NONA GALLION, of Liberty Street, a nine pound girl. Thanks to Dr. Wallingford."

One would suppose that Messrs. Flamin and Gallion would claim some thanks.

Society Reports.

MASSACHUSETTS MEDICAL SOCIETY.

One Hundred and Seventh Anniversary, held in Boston, Mass., Wednesday, June 13, 1888.

[Special Report for The Medical Record.]

On Tuesday, June 12th, preceding the day of the annual meeting, the Fellows of the Society visited, during the morning, the Massachusetts General and City Hospitals, where a large number of interesting operations were performed by the visiting surgeons. The Children's and Carney Hospitals were also open to the visiting Fellows.

In the afternoon the Fellows met in Huntington Hall, where the following papers were read: "Private Mental Sanitaria and the Inebriates," by Austin W. Thompson, M.D., of Northampton; "Therapeutic Nihilism," by Maurice D. Clarke, M.D., of Haverhill; "Uterine Displacements and their Influence on the General Nervous System," by Francis H. Davenport, M.D., of Boston; "The Modern Practice of Surgery," by Otis K. Newell, M.D., of Boston; "The Treatment of Hypertrophy of the Prostate with Especial Reference to Operative Measures," by Francis S. Watson, M.D., of Boston; "A Study of Phthisis and Pneumonia in Massachusetts; Statistical and Climatological," by W. Everett Smith, M.D., of Boston.

At the Institute of Technology, during both days of the meeting, there was an interesting exhibit of drugs, chemicals, pharmaceutical preparations, foods, surgical instruments and appliances, apparatus relating to hygiene, and medical books.

At the meeting of Councillors, held in the evening at 19 Boylston Place, the following officers were elected: President, David W. Cheever, Boston; Vice-President, George Jewett, Fitchburg; Treasurer, Frank W. Draper, Boston; Corresponding Secretary, Charles W. Swan, Boston; Recording Secretary, Francis W. Goss, Roxbury; Librarian, Edward H. Brigham, Boston; Orator for the next Annual Meeting, Henry P. Wolcott, Cambridge; Anniversary Chairman, James R. Chadwick, Boston.

On Wednesday, June 13th, the annual meeting was opened at 9 A.M., in Huntington Hall, Dr. Gage presiding.

The report of the Recording Secretary, Francis W. Goss, contained a list of the fellows admitted during the year, and also of those deceased. The report of the Treasurer, Dr. F. W. Draper, showed that the receipts for the year were $11,350, and the expenditures $8,789; also that the number of members in the Society was now 1,692. It was decided, in accordance with the recommendation of the Council, to amend the conditions of admission to the Society to the extent of making membership open to candidates of all schools, after passing an examination before the Board of Censors. Among communications read by President Gage was one from the State Medical Society of Georgia, asking the co-operation of the Society in an appeal to Congress to remove all import duty from medicines and surgical appliances; another from the State Medical Society of Arkansas, entering a protest against religious journals advertising proprietary medicines, and against clergymen recommending the same. A report was next read from the special committee appointed at the last annual meeting to investigate the subject of physical culture in schools. It called the attention of the Society, first, to the need of some method of physical culture, particularly for the children of large cities and towns; second, to what has already been done in some quarters toward providing this need; third, to a consideration of what seems to be practicable for schools, and particularly the public schools, to undertake for the physical training of their pupils.

The following papers were then read:

"Postural Treatment of Constipation," by Edward T. Williams, M.D., of Roxbury; "The Surgical Treatment of Malignant Growths," by Maurice H. Richardson, M.D., of Boston; "The Value of Corrosive Sublimate as a Practical Disinfectant," by William B. Hills, M.D., of Cambridge.

At one o'clock the fellows and guests, under the leadership of Dr. Swift, walked in procession to the Hotel Vendome, where, in the parlors of that establishment, which had been prettily embellished for the occasion with plants, grasses, and flowers, a reception took place and refreshments were served. The members of the Receiving Committee were His Excellency Governor Ames, Dr. Oliver Wendell Holmes, Rev. Phillips Brooks, Dr. Francis Minot, Rev. Eward E. Hale, Dr. G. C. Shattuck, Dr. B. E. Cotting, Dr. Cogswell, Alfred Hosmer, of Watertown, Dr. Henry I. Bowditch, Dr. Henry P. Bowditch, Dr. Henry W. Williams; Surgeon-General Holt, of the governor's staff; Rev. Philip Moxon, Dr. William N. Ingalls, Dr. George H. Lyman, Dr. William Cogswell, Dr. D. W. Cheever, Dr. Thomas H. Gage, of Worcester, Dr. Charles P. Porter, and Dr. B. Joy Jeffries. In addition to the above, there were among the guests Hon. G. H. Hale, Messrs. Causten Brown, William Endicott, Jr., Professor C. S. Minot, George A. Gordon, Professor G. G. Gardner, Passed Assistant Surgeon Stephenson, U. S. N.; Rev. M. G. Savage, Rev. Stopford Brooke, Medical Director R. C. Dean, of the Chelsea Naval Hospital, and many others. The entrance was in charge of Dr. Gannett, the dining-room was in charge of Dr. V. Y. Bowditch, and the parlors were in charge of Dr. Ernst. The Committee of Arrangements was made up of Drs. J. B. Swift, H. C. Ernst, W. W. Gannett, O. K. Newell, V. Y. Bowditch, and F. B. Harrington. The music was provided by Baldwin's Cadet Band and Orchestra.

OHIO STATE MEDICAL SOCIETY.

Forty-third Annual Session, held in Columbus, O., June 13, 14, *and* 15, 1888.

Dr. Samuel F. Forbes, of Toledo, President, in the Chair.

Secretary, Dr. G. A. Collamore.

(Special Report for The Medical Record.)

Mayor Bruck, of Columbus, made

THE ADDRESS OF WELCOME,

in which he said the art of curing disease was one of the most important subjects which could be brought before a community; referred to the well-known high esteem in which physicians are held by the sick, how this esteem vanishes when again well, and the labor so highly appreciated at the time is often grudgingly or not at all paid for at a later date. He thought the aims of the Society, the cultivation and the advancement of medical science and literature, and the advancement of the standard of medical education, the maintenance of union and harmony among its members, and the promotion of the character and usefulness of the profession, were truly commendable, and should attract to their body all physicians who have a proper appreciation of the honorableness and high standing of the profession. It is an old saying that the sun shines on their success, while the earth hides their blunders. But he was inclined to think that their success was as much greater than their mistakes as the sun was greater than the earth. He noticed on last Sunday morning one of their most prominent undertakers out walking with his whole family, a circumstance which had not happened before, he thought, in his whole professional experience—to be without a funeral on a Sunday morning. The alarmingly perfect state of the health of the community must be aggravating to them, but if they were there to unload an epidemic on it, he wished it given in homœopathic doses. He hoped the meeting would be of much profit to the members, and that they would bear with them pleasant recollections of their visit to Columbus. The address was heartily applauded.

REPORTS OF DELEGATES.

Reports of the Secretary, Treasurer, and various committees were made. Delegates to the American Medical Association made reports. Dr. E. S. McKee, delegate to the British Medical Association, reported that his visit to this association had been one of the most pleasant and one of the most instructive of his life. The mother association he found superior to our own in some respects, inferior in a few, and similar in many. The political doctor played quite as prominent a rôle in the British as in the American Association. Quarrels and sectional strife were as frequent and as bitter. The English doctor, as is perfectly natural for an Englishman, thinks himself superior to his Irish or Scotch brother. This shows itself in various ways; among others, in the advertisements of charitable institutions to fill vacancies in the staffs of said institutions. These advertisements read, "No Irish or Scotch need apply," or words to that effect. This the Irish and Scotch resent. This resentment took the form of a resolution at Dublin demanding that this practice on the part of English institutions be discontinued, and declaring the qualifications of the different branches of the United Kingdom to be on the same footing. This produced a bitter discussion, but, the meeting being on Irish territory, it was carried through with a cheer. The efforts of our Irish brethren, in the direction of legislation, seem to be about as persistent and as fruitless as with us. The reports of the various committees could be summed up as follows: "We have done everything possible; we have accomplished nothing." He was especially pleased with the efforts on the part of the committee to secure legal control of the habitual drunkard. The finances of the institution were in a solid condition. The Association now owns its premises on the Strand, in London, where are the permanent headquarters and the place of publication of the journal. The annual income exceeds the expenditures, and leaves a comfortable remainder each year. The membership is about 12,000, of whom about 1,200 were present. Their membership is different from ours, in that it includes the members of all of the auxiliary societies. In the sections there was quite an amount of good scientific work done. His time was spent almost exclusively in the Section on Obstetrics and Gynecology. Dr. A. V. Macan, Master of the Rotunda Lying-in Hospital at Dublin, was the President of the Section, and in a masterly address gave prominence to the practice of the obstetric art in the Rotunda. The doctor made a very good executive officer, cutting off the long-winded bore, and drawing out the man whose erudition was only measurable by his modesty. In calling for discussion he would not say, has any gentleman anything to say, but, has any gentleman anything *new* to say? Under his command very little time was lost and much work accomplished. This Section was highly favored by two papers by Dr. Apostoli, of Paris, on his method of treating fibroid tumors of the uterus and endometritis. The Section was treated to a demonstration, in the Rotunda, of Apostoli's method of applying electricity in the treatment of fibroid tumors of the uterus by that gentleman himself. In social matters the British far excel us. Their meeting was accompanied by a perfect round of social entertainments. Not only were they dined and wined, but were given suppers, luncheons, and even breakfasts, with garden-parties, soirées, receptions, balls, and sermons. There may be people starving in Ireland, but certainly not suffering for anything to drink; for he never saw as much as was put before them at Dublin. The Ohio State Medical Society can feel itself honored in the manner in which its delegate was received by the British Medical Association. His visit was made much more pleasant than had he gone there without his delegate's papers.

The election of officers resulted as follows: President, P. S. Connor, M.D., LLD., Cincinnati; First Vice-President, Dr. D. Halderman, of Columbus; Second Vice-President, Dr. B. M. Ricketts, of Cincinnati; Third Vice-President, Dr. A. H. Brundage, Xenia; Fourth Vice-President, Dr. A. M. Brown, Hillsborough; Secretary, Dr. G. A. Collamore, Toledo; Assistant Secretary, Dr. E. C. Brush, Zanesville; Treasurer and Librarian, Dr. T. W. Jones, Columbus. Various committeemen were also elected. So much time was occupied in the election of officers that, on motion of Dr. Dudley P. Allen, of Cleveland, in the future all officers, except the President, will be referred to a committee of five for nomination. The selection of a place of meeting for next year was rather difficult, on account of the number of invitations made. Put-in Bay, Columbus, Youngstown, Canton, Delaware, were presented, and their various qualifications urged by their champions. After much debate, the selection fell to Youngstown.

Socially, the Society was entertained with receptions at the residence of Dr. Starling Loving, Dr. J. W. Hamilton, Dr. W. D. Hamilton, and at the Central Ohio Lunatic Asylum, all of which were very highly enjoyed.

The President, DR. SAMUEL F. FORBES, of Toledo, made the usual address, in which he reviewed

THE HISTORY OF MEDICINE TO THE PRESENT DAY.

He gave the college faculties the usual going over. He recommended that students of medicine be compelled to pass the county examinations for school-teachers. We require this of the school-teacher, and why not of the doctor, with whom we trust our lives? He thought that the laws proposed so far had been too sweeping. They were not too radical to be right, but only for the tender feelings of the legislator. If we did not ask for so much, we would be more apt to succeed. He recommended that we endeavor to get a law passed requiring everyone practising medicine to have his diploma registered with the county recorder. We are all of us but students of older growth than those in our offices and colleges. If we give proper attention to our duties, then are we students for life. Professional fraternity, he thought, should be especially strong among physicians.

DR. R. HARVEY REED, of Mansfield, repeated the experiments performed by Professor N. Senn at the Cincinnati meeting of the American Medical Association, of

INJECTING HYDROGEN GAS INTO THE RECTUM OF A DOG, AND BURNING IT AS IT PASSED FROM A TUBE INSERTED INTO THE ŒSOPHAGUS.

The experiment was a success in every particular, and created a good deal of interest. He thus demonstrated the fact again that the ileo-cæcal valve is not impassable. He then cut in upon the ileo-cæcal valve and allowed the gas to escape from it.

DR. DUDLEY P. ALLEN, of Cleveland, read a paper upon

THE RADICAL CURE OF HERNIA,

presenting two cases upon which he had operated. The first was a child, upon whom the operation had been performed eighteen months since; the second case, a man, aged twenty-five years, with a hernia the size of a child's head, and an opening into the abdominal wall about four inches in length.

Both cases have resulted successfully, and were presented to illustrate the method of operation. This is to ligate the hernial sac as high up as possible and cut it off, then unite the pillars by interrupted sutures, leaving one end long. The wounds were dressed antiseptically for the first week, until all danger of infection of the abdominal cavity had ceased. After this the wound is allowed to granulate, and as the sutures separate they are pulled away. Though it is not claimed that this method of closing the ring is superior to that of closing it by first intention, still, the cases were presented to demonstrate the fact that cases operated upon by this method may be successful, even with an enormous abdominal cavity.

The patient with the large hernia has been a laborer in a rolling-mill for three years and has never worn a truss, and is perfectly cured.

Dr. A. W. Ridenour, of Massillon, read a paper on

THE RADICAL CURE OF HERNIA,

in which he discussed the different varieties of hernia and the manner of reduction, after which the two papers were discussed.

Dr. P. S. Connor, of Cincinnati, read a paper on malpractice suits. Having just passed through a suit, the doctor was specially qualified to speak. In the vast majority of instances, he said, malpractice suits are brought with an intention to rob—a species of blackmail. So long as rascally lawyers and scoundrelly doctors have an existence, malpractice suits would exist. There seemed to be an epidemic of them in the State at present. The doctor then read a bill which is in force in the State of New York, to protect physicians, surgeons, and dentists, and others from speculative malpractice suits. This bill requires that bond be given equal to twice the amount of the sum claimed as damages, and in case the suit be lost or dismissed, this sum be collected. With such a law as this on their statute-books they would have all they wanted. Persons would be more careful how they brought or encouraged malpractice suits. If one has been really injured, he can readily get the necessary support; if not, he will be more careful what he tries to do. The doctor then presented a resolution requesting that a special committee be appointed to present to the General Assembly of Ohio, at its next session, a bill similar to the one now on the statute-books of New York. The resolution was adopted.

CONTAGIOUSNESS OF DISEASE

was the subject of a paper by **Dr. H. J. Herrick**, of Cleveland. He did not believe much in the germ theory, especially in respect to consumption. The paper was discussed by Drs. R. Harvey Reed, of Mansfield, and J. F. Baldwin, of Columbus, both expressing themselves as disbelievers in the germ theory or contagiousness of consumption. The

THERAPY OF TUBERCULOSIS

was the subject of a paper by **Dr. J. T. Whittaker**, of Cincinnati. The doctor started with the statement that five-sevenths of mankind suffer at one time or another with tuberculosis. That many have tuberculosis in some form, and recover, is proven by post-mortems. One-seventh of the population of the globe die of one manifestation of this disease, tuberculosis pulmonum. Twelve died the day before in Cincinnati of consumption; others, of convulsions, meningitis, and other complaints really tubercular. Six years ago Koch announced his discovery, and it remains unbroken. The hope that practical results would obtain has not been realized, and pulmonary tuberculosis remains as intractable as before; yet to-day no treatment of tuberculosis is scientific which does not refer to the bacillus. Koch has made his discovery, and it is the duty of the clinicians to cure the disease on the basis of this discovery. Elevation, in its good effects, is probably due to increased lung-exercise. High altitudes require three times as much exercise as at the sea-level. Fresh-air gymnastics, as Sydenham said of horse-back riding, bears the bell. Cod-liver oil has done more for consumption than all other therapeutic remedies put together. The food of the highest force-value is alcohol. Four tablespoonfuls of cod-liver oil will only produce about one-half as much heat-force as a bottle of good wine, and four tablespoonfuls is about all that a patient can stand in a day. Alcohol, fresh air, and cod-liver oil are no new remedies in the therapy of tuberculosis. The bacillus is the smallest and the most difficult to destroy. Boiling for twenty minutes, or corrosive sublimate 1 to 1,000, is necessary to kill it. After experimenting for one year, he had come to the conclusion that no inhalation would kill the bacillus, and had entirely abandoned it. He had also tried corrosive sublimate by inhalation and parenchymatous injection, without success. He has had one year's experience with creosote, increasing it one drop per day until twenty-five or even forty drops were given a day. Guaiacol, he found, had no superiority over creosote. Aline sulphide, the essential principle of garlic, caused quicker results in his hands, but the scent of the garlic was unbearable. He has experimented with the oil of black mustard for a month past, and has had some very marked improvement in his patients, although the time is too short to allow of speaking with authority. He hoped some of his hearers would take up the subject and assist him.

Dr. Herrick, of Cleveland, said he was held up as a heretic, yesterday, and he believed he was. Dr. Whittaker holds up his hands and says he is as unable to cope with it as ever. I do not believe in the germ theory of tuberculosis. I think the bacillus is not the cause, but the result. The disease is only a disturbed nutrition. He took issue with Dr. Whittaker as to his notions of alcohol as a heat-producer in the body. Always, in tuberculosis, we find antecedent disturbance of the digestion.

Dr W. J. Scott, of Cleveland, had given the subject his very best attention, and he did not believe that healthy, well people are liable to contract tuberculosis. He thought that the bacillus had more endurance than the patient.

Dr. J. T. Whittaker, of Cincinnati, had heard with pleasure the remark of the first gentleman. It sounded as a chapter from history, a review of the pathology of Hippocrates, where we read so much of this humor which is in the blood. It comes over us like the wind from a bank of violets. Then he says, sweat it out, while another gentleman says too much sweat produces tuberculosis. Dyspepsia does occur frequently; in fact, in about one-third of the cases. Ninety per cent. of all cases show ulcer of the intestinal canal. The gentleman must ignore all cultivation-experiments. We can introduce the bacillus into the body of the healthy animal and produce tuberculosis. I think the time will come, and it is not more than a decade distant, when we will throw away the stethoscope and make our diagnosis of tuberculosis by an examination of the sputa. This is now so simplified that it can be made in fifteen minutes in the presence of the patient. This bacillus is a vegetable seed. How can an animal tissue cause a vegetable seed? It must be brought from without. This bacillus is a stumbling-block to the theory of inheritance. It is very questionable if tuberculosis is ever inherited. It must be made a crime not to disinfect the sputum. A man might as well walk about the streets firing a loaded revolver as expectorating tuberculous sputa right and left.

Dr. W. J. Scott, of Cleveland, reported four

CASES OF DIABETES MELLITUS

which he did not cure. They were cases on which he had tried the diet-method recommended by Dr. Pavy at the last International Medical Congress. He remarked that there were cases which could be cured by diet, and there were others which could not be cured by diet or by medication.

Dr. B. Merril Ricketts, of Cincinnati, read a paper on the

TREATMENT OF ACNE,

a subject which he thought neglected. He had found massage beneficial in some cases, especially the abdominal massage, which is given for constipation, and is well accompanied with Turkish baths. Fluid extract of ergot, given in half-drachm doses after each meal, is supposed to do good by contracting the superficial blood-vessels. Iron, arsenic, and strychnia are serviceable as tonics; gr. $\frac{1}{5}$ of arsenious acid given with the elixir of gentian, tr. ferri chloridi, with a few drops of hydrochloric acid after each meal, gradually increased till gr. $\frac{1}{2}$ or $\frac{3}{4}$ is taken daily, is by far the best I have given. External treatment: Apply hot water for fifteen or twenty minutes, then thoroughly remove all sebaceous matter. At the end of this time a stimulating paste, composed of ichthyol and wollin or lanolin, should be applied once or twice a day. Resorcin, with subnitrate of bismuth, zinc oxide, and mollin or lanolin, is also very good.

Dr. William T. Corlett, of Cleveland, read a paper on

DISEASES OF THE SKIN DUE TO DEFECTIVE ALIMENTATION.

He reported a number of cases and described the treatment, and deduced the following principles:

Those having an irritable skin should avoid the use of, in youth, rhubarb, the small seed fruits, apples, shell-fish, sugar, and acids sparingly, malt liquors and spirits; in old age, lean meat, eggs, beans, shell-fish, pastrics, malt liquors, and spirits. Wholesome foods may become unwholesome by improper cooking, as hot cakes, heavy puddings, etc.; by defective mastication, either by eating too rapidly, or from loss of teeth. Man is an omnivorous feeder and cannot thrive on bread alone, neither can he maintain a healthy skin on an exclusive diet of meat.

Dr. H. M. Brown, of Hillsborough, read on

PAINLESS TREATMENT OF RECTAL DISEASES.

His treatment consisted largely in the use of cocaine. He had watched with mingled wonder and curiosity the moneyed people of his community making haste to their specialist, their so-called rectal saviour, and thought to add to his exchequer by learning something of his ways. His investigations had proven quite beneficial, both to his patients and to himself.

INDIANA STATE MEDICAL SOCIETY.

Thirty-ninth Annual Session, held in Plymouth Church, Indianapolis, June 5, 6, *and* 7, 1888.

The Secretary, Dr. E. S. Elder, reported that special attention had been paid during the past year to the organization of new societies and the reorganization of old ones. There are now 74 county societies, and 1,200 contributing members; 53 auxiliary societies, with a membership of 764. There have been 19 deaths during the past year.

The Treasurer, Dr. C. B. Higgins, of Peru, reported receipts as $1,266.63; balance on hand, $270.36.

The President, Dr. S. H. Charlton, in his address, said that thirty-nine years ago this Society was organized with a membership of thirty, of whom only six are now living. These pioneers of medicine in Indiana suffered many privations, which he related; then went on to the subject of medical education. The medical student should have a preliminary education before he enters the study of medicine. Doctors ought to refuse to accept students who would not add to the dignity of the profession. There is, he said, no nobler work for the philanthropist than to look after the health of the State. This Society, after long effort, has finally secured a health board for this State. More stringent laws regarding quackery are needed. Recent discoveries with the microscope show that there has been greater activity in the medical profession during the last twenty years than ever before. He hoped that one of the triumphs of the profession would be that through their efforts the moral status of mankind would be heightened. Modern science is founded upon experience and observation, and is growing more practical every day. Within the range of history, science, and art, there is nothing which has advanced so rapidly in the last fifty years as medicine.

The banquet at the Dennison was a grand affair, over five hundred plates being laid. Governor Porter was present.

The number of members present at the meeting was about three hundred.

The Blind in Egypt.—It is stated that one person in every twenty in Cairo is blind.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE TUBERCLE BACILLUS AND ITS VALUE IN DIAGNOSIS AND PROGNOSIS—RECENT MEETING OF THE MEDICAL COUNCIL—A MODIFIED SYSTEM OF MEDICAL PUPILAGE—THE DEVELOPMENT OF ENGLISH HEALTH-RESORTS—METROPOLITAN SEWAGE—A REPRIEVE—COSMOPOLITAN MEDICINE—DR. FORDYCE BARKER IN LONDON—DISCUSSION ON INTUSSUSCEPTION AT THE CLINICAL SOCIETY—REPORT OF THE MYXŒDEMA COMMITTEE—DR. KÜHNE'S CROONIAN LECTURE ON THE CAUSATION OF VITAL MOVEMENTS—THE COLLEGE OF SURGEONS—LEGISLATION FOR HABITUAL DRUNKARDS.

London, June 2, 1888

The tubercle bacillus is not of much value in prognosis. Such, at least, is the verdict given by Dr. Percy Kidd and Mr. H. H. Taylor, in a joint paper by them read before the Medical and Chirurgical Society. Dr. Kidd said they had often found cases in which the disease was making rapid progress but the bacilli were scanty, and a chronic stationary case in which they were very abundant. As regards diagnosis they expressed a very different opinion, and it was to the value of the detection of the bacillus as an aid to diagnosis that their paper was mainly devoted. In over ninety cases in which other recognized methods of clinical investigation had failed to indicate a definite diagnosis, a positive result had been obtained by means of the sputum test. The detection of the tubercle bacilli in such cases was often extremely difficult, and repeated examinations might be needed where the bacilli were scanty. The time thus spent would, however, be well repaid when, as often happened, a positive diagnosis could be arrived at without delay, and without waiting for the progress of the case. Success depended largely on judiciously selecting the sample of sputum, on employing only the best methods of preparing and staining, and on examining with suitable appliances. The bacillus had been found useful for diagnosis in five groups of cases: (1) Those without physical signs of disease of the respiratory organs; (2) laryngeal disease of uncertain nature without definite pulmonary signs; (3) bronchitic cases, with or without emphysema; (4) in cases with signs of pleurisy; and (5) where only signs of doubtful import were present, such as (*a*) anomalous physical signs, (*b*) slight signs at the apex, and (*c*) signs confined to, or most marked at, the base.

Dr. Theodore Williams said it would be a pity if attention to the bacteriological part of the subject were to interfere with the careful examination of all previously available physical signs. He had had visits from Germans who had had bacilli found in their sputa by a pharmaceutical chemist, and whom the chemist had proposed to treat; that was a result not to be approved. He thought the examination of the sputa for bacilli was of great value in the diagnosis of laryngeal disease, and of even greater value in cases of bronchitis and emphysema, where the tubercular affection was masked by the other diseases. He thought that the examination for bacilli might also prove useful in cases of pyrexia and wasting without any pulmonary physical signs, and in senile cases where the tubercular disease was masked by bronchial catarrh. He did not agree with Dr. Kidd and Mr. Taylor that the bacillus was of little use in prognosis; the bacillus was sometimes important in cases of arrested phthisis which might come on again, and it might thus be of special importance in giving or refusing medical consent to marriage. Dr. Douglas Powell agreed with the authors of the paper that the bacillus was valuable in diagnosis, but not of much use in prognosis. In laryngeal cases it might show phthisis when the physical signs had been masked by an aneurism. He remarked that he had known physical signs to precede bacilli. Dr. J. K. Fowler bore testimony to the value of examining for bacilli in cases of spare men with bronchitis and some emphysema. Such cases were not infrequently cases of arrested phthisis.

The Medical Council have been meeting again during the past week. As usual, a large amount of time has been spent in mere routine business. In moving the adoption of the report of the Pharmacopœia Committee, Dr. Quain congratulated the council on the fact that there was a profit of twelve hundred pounds on the book. Referring to the question of the Pharmacopœia being the standard authority for the composition and preparation of the medicines therein described, he said it had been decided by a magistrate that there was no authority to make any work a standard of the strength of drugs, and it was therefore possible to sell laudanum containing only half the quantity of opium, and paregoric which did not contain any opium at all. If this were permitted fatal accidents might easily arise. Two additional examiners in surgery were appointed to the Society of Apothecaries, thereby still further confirming the status already accorded to the diploma of that body. An important discussion then took place on the report of the Education Committee. The committee seemed disposed to partially revert to the old system of pupilage. After some discussion their recommendation on this subject was adopted in the following modified form: "That in addition to the requirements at present in force with respect to hospital attendance and duties, all candidates for the final examination be required to produce evidence that they have attended, under proper supervision, for six months, the practice of a recognized public dispensary, including the visitation of patients at their own homes, or the outdoor practice of a recognized hospital, or have acted for six months as pupil to a registered practitioner, either holding such a public appointment or having such opportunities of imparting practical knowledge as shall be satisfactory to the examining bodies." The committee also recommended that all candidates be required to produce evidence of having practically studied the subject of fever. The subject of irregular practice also occupied the attention of the council. One medical man who acted as "cover" to an unqualified practitioner was let off with a caution, while a dentist had his dental diploma removed from the register.

A good deal has been done within recent years to develop the health-resorts of the United Kingdom. It has now been pretty generally recognized that in order to establish a spa on a good basis it is very desirable to obtain the hearty support of the profession. Where this has been done, as at some of the best known health-resorts, they have made rapid strides. At many places, also, a good deal has been done in the way of providing amusements of various kinds. Had all these measures been adopted years ago it cannot be doubted that many invalids would have found it more convenient to visit some of the spas of England instead of those on the Continent. These remarks occur to me apropos of the opening ceremony in connection with the new pump-room and baths at Woodhall Spa, which took place a few days since. A number of medical and other visitors were present. Dr. Burney Yeo remarked that those who desired to promote the prosperity of English spas must bring about developments in the way of amusements which few of them at present possessed. The invalid did not merely want water and baths, but means of amusement; if well amused he was half cured.

Sir Robert Rawlinson, the eminent sanitary engineer, has lately delivered himself strongly against the system of sludge precipitation for the London sewage being adopted by the Metropolitan Board of Works. The only way, he says, to deal with crude sewage is to irrigate land with it.

A Yorkshire medical man, Mr. Burke, who lately shot his daughter and was sentenced to be hung for the murder, has just been reprieved. Strong evidence has been adduced that he was not responsible for his actions, having, in fact, attempted his own life only a few months ago.

LONDON, June 2, 1888.

The increased facilities for locomotion afforded nowadays practically render the world smaller year by year. Our own profession consequently becomes more cosmopolitan and less hidebound by mere local traditions. A marked feature of the last few annual meetings of the British Medical Association has been the presence of several foreign medical men of eminence to take part in the discussions. One of these (Dr. Apostoli, who was present at the Dublin meeting of the British Medical Association) also took part in a recent meeting of the Brighton and Sussex Medico-chirurgical Society, and defended his method of electrical treatment for uterine diseases from the imputations made against it that it is dangerous. He admitted, though, that it might become so in inexperienced hands, if antiseptic precautions were not carried out, or if the rules he had laid down were not observed. Dr. Fordyce Barker, of New York, was present at the last meeting of the Clinical Society, and received a hearty welcome. He was invited by the President (Dr. Broadbent) to take part in a discussion on intussusception following the reading of a paper on the subject by Mr. R. W. Parker. Dr. Fordyce Barker said he had seen a number of these cases of acute intussusception in infants. Surgery, he remarked, did not seem to offer much chance of curing the condition. In early stages of the disease he would inject glycerine in small quantities, such as one or two drachms, with equal quantities of water, until toleration was established. He would then continue the injections until a large amount was used. Mr. Harrison Cripps concurred with Mr. Parker as to the danger of injecting water except in the early stage, and referred to a case of his own so treated which had ended fatally. He also mentioned another case in which considerable sloughing of the bowel occurred, but the child recovered. Eight months later, the child died from scarlet fever. At the autopsy the small intestine was found directly attached to the anus, the whole of the large intestine having sloughed away. The President referred to the value of gaseous injections. Mr. Parker said that, should another opportunity occur, he should remember Dr. Fordyce Barker's suggested plan of treatment. Early treatment, he thought, should consist of enemata of water, which was probably better than air, as one could easily calculate the quantity injected. Mr. Herbert Page then read a paper in which he described two fatal cases of rupture of the intestine occurring without external wound. Mr. Croft read notes of a similar case. Dr. Ward Cousins described a case of stone in which lithotomy was performed twice within two months. At the same meeting, which was the concluding one of the session, the report of the Myxœdema Committee was presented by the chairman of the committee, Dr. Ord. This, indeed, was one of the most important incidents of the meeting and preceded the other business. The conclusions (fifteen in number) arrived at by the committee, are too lengthy to quote here in full, but I may say that they confirm, on the whole, the current views on myxœdema. Its connection with destructive changes in (or removal of) the thyroid gland is fully recognized, and the committee express the opinion that the disease described under the name of "myxœdema," as seen in adults, is practically the same as that named "sporadic cretinism" when affecting children; that myxœdema is probably identical with cachexia strumipriva; and that a very close affinity exists between myxœdema and endemic cretinism. They state, in conclusion, "that while these several conditions appear, in the main, to depend on, or to be associated with, destruction or loss of the function of the thyroid gland, the ultimate cause of such destruction or loss is not at present evident."

The Royal Society's Croonian Lecture was delivered on Monday last by Dr. W. Kühne, Professor of Physiology in the University of Heidelberg. He took for his subject "The Causation of Vital Movements." He pointed out the functional as well as the morphological unity of all living matter. The cause or protoplasmic movement, he said, could only be internal, in the contractile substance itself, and could only consist of chemical processes taking place within the mass. Experimental researches showed that there was a striking agreement between the irritability of protoplasm and that of muscle. Dr. Kühne then traced the transition to the highly developed motor apparatus which distinguishes the animal kingdom from almost its lowest stages; viz., the bicellular apparatus, consisting of separate cells united together, one of these presenting the exciting nerve, the other the obedient muscle. Some specimens were exhibited, showing that the terminations of nerves in muscle are localized. Portions of muscle free from nerves were demonstrated to twitch when stimulated. The lecturer also showed experimentally that one muscle could excite another electrically.

The Central Committee of the Association of Members of the College of Surgeons have forwarded a petition to the Privy Council, praying for further consideration to their claims in connection with the charter about to be granted to the College.

The bill in reference to habitual drunkards has passed the second reading in the House of Commons, and there is therefore a chance of its becoming law this session.

ON THE REMOVAL OF OPACITIES OF THE CORNEA BY MEANS OF GALVANISM.

To the Editor of The Medical Record.

Sir: The purpose of this note is to call, or rather recall, the attention of the profession to the therapeutic value of the galvanic current in the treatment of opacities of the cornea. Some cases I have now under observation appear to show that this application of electricity has been allowed to fall into undeserved desuetude. I cannot offer yet complete results of treatment to support this claim, but the following statement may serve to show that it is worthy of some attention. In February last I began to use the galvanic current for the removal of an opacity of the cornea without knowledge that it had been so used before. The case was one of recent macula of both corneæ, visible at a distance of several feet. It has now wholly disappeared from one eye and is barely discernible in the other, from which I expect continued use of the remedy to remove all trace of blemish and defect of vision. Another case, taken up a few days later, a kidney-shaped macula about two and a half lines in length, is now represented by a thin speck-like spot which the patient and her friends no longer see. This, too, is steadily melting away. Of the seven other cases under treatment it will suffice here to say that they varied in size from that of a millet-seed to the whole circumference of the cornea, from a nebula to a dense white leucoma, and in duration from forty days to forty-eight years.

All of these cases are steadily improving, two of the most extensive maculæ being merely fragmentary remains of the original, while the corneæ elswhere are quite clear. The rate of disappearance seems to depend chiefly upon the size of the opacity, which, like a heap of snow, melts away from the periphery toward the centre, the oldest but little more slowly than the most recent.

The method I have employed is as follows: One pole of the battery in the palm of the hand, the other upon the closed eyelid, ordinary sponge-covered electrodes being used. If the eye is or becomes in the least congested or the seat of pain, the anode should be placed there; otherwise the cathode should be used as the therapeutic pole, its action being more rapid, apparently. The strength of the current should not exceed three milliampères, and with sensitive eyes a strength of two milliampères is better. The sitting should not extend beyond three minutes, unless the eye shows, after trial, unusual tolerance of the current; a five minutes' sitting sometimes irritates the organ. An application was made daily at first, but this was found to be too frequent—productive of irritation. Sittings are now held every other day without discomfort in any case.

A galvanometer and a smoothly working galvanic battery are indispensable in this treatment. I am using Barrett's milliampère-meter and chloride-of-silver battery.

Very respectfully,
C. H. H. Hall,
Passed Assistant Surgeon.

U. S. Naval Hospital, Yokohama, Japan,
May 16, 1888.

OXALATE OF CERIUM IN SEA-SICKNESS.

To the Editor of The Medical Record.

Sir: In The Medical Record for June 2d I have read with pleasure an article on the use of oxalate of cerium in sea-sickness. For the benefit of those who suffer from that malady, I wish to offer my testimony also.

The value of oxalate of cerium in sea sickness has been known to me for years. Its application to this condition suggested itself from its supposed physiological action. I had never heard of its use by any other physician until the reading of the article above mentioned. After repeated experiments on myself and others, I am satisfied that it will relieve more cases of sea-sickness than any remedy yet suggested. I have tested its efficacy both in coast and transatlantic voyages.

Last summer I crossed the ocean with a party of friends. One of the number proved perverse, and would not take the remedy I offered. As the passage was somewhat rough, she was rewarded by being confined to her state-room during nearly the entire voyage. Another member of the party, hitherto a hopeless victim of sea-sickness, who had, in crossing the ocean fourteen times, made use of every known remedy without benefit, obtained decided relief from the oxalate of cerium. Two others, not "good sailors," took it regularly, from the time of going on board until the motion of the steamer ceased to be unpleasantly suggestive, and were kept from any serious symptoms, omitting, in all the passage, but one meal on a stormy night.

The best results were obtained by fifteen-grain doses given every two hours. It can easily be taken dry, on the tongue, and I believe this mode of administration is most effective.

I am, sir, yours very truly,
M. M. Waldron, M.D.

Hampton, Va., June 6, 1888.

TEACHING THE DEAF IN THE PUBLIC SCHOOLS.

To the Editor of The Medical Record.

Sir: My attention has been called to an editorial on "Auxiliary Public Schools for Feeble-minded and Backward Children" in The Medical Record for May 26th. I read with interest that it was the writer's belief that it would be most humane and economical in the end for the State to undertake to educate the defective classes, as well as the healthy.

I am engaged in teaching children who are more or less hard of hearing, and I feel sure that class of pupils should receive more attention in the public schools. Time and money spent upon feeble-minded children may accomplish almost nothing; in contrast, hard-of-hearing children, properly educated, become very useful members of a community, thus fully repaying all efforts made in their behalf. There are many such children in New York. Dr. Samuel Sexton, in a pamphlet on the subject, expresses as his belief that there are no less than five hundred of school age, unprovided with educational facilities, and many more in the schools who could be helped by instruction at close range, or by means of some aid to hearing.

We cannot divide children into two general classes—those who hear well and those who do not hear at all. Hearing disabilities are of all degrees of deafness, ranging from slight defects to absolute incapacity. Frequently a mild form of deafness is not recognized by teachers, and it may be accompanied with defective vision; and, too often, children are unjustly pronounced dull and stupid. They are certainly in as great need of education as any others; they have too much hearing to be classed as deaf-mutes, and they are too deaf to progress in the ordinary schools. Parents who have the means to employ private teachers like myself, do so.

In what way, however, could matters be arranged so that all could be educated to advantage? By forming classes of not more than ten pupils, wholly or partially deaf, and having them instructed by specially trained teachers, the Board of Education could reach every case of deafness. Each child could receive its right to be educated at home, and parents would not have to endure the grief of placing their little ones at school at a distance.

Various day-schools for the deaf are prospering in Boston, Eric, Chicago, Cincinnati, Portland, St. Louis, and Milwaukee. There is every reason to think such schools or classes in the public schools in various parts of New York would do valuable work. The State pays $250 annually for every child in an asylum for deaf-mutes. At less than the cost of three such a teacher could be procured to instruct ten children; in this way the totally deaf and the partially deaf could be cared for at less expense than is now borne by the State in conducting deaf-mute institutions.

This is no new thought. Efforts were made in 1877 and in 1884 to persuade the Board of Education of this city to make some changes in regard to the defective in hearing. The matter was referred to the Committee on Course of Study; so far as is known, the committee has not made any report to the Board. It is hoped some steps may be taken in this matter.

Lillie E. Warren.

239 West Twenty-first Street.

THE JUICE OF THE CENTURY-PLANT IN BRIGHT'S DISEASE.

To the Editor of The Medical Record.

Sir: I desire to call the attention of the medical profession, through the columns of your journal, to the almost wonderful effects of the juice of the maguey or century-plant on all cases of albuminuria. This plant is a native of Mexico, and its juice or sap forms the principal drink of the natives of this republic. During my more than three years' residence in this country, I have never met with a case of Bright's disease among those who habitually use this product; and it is my universal treatment in all diseases of the kidneys where albumen is found in the urine.

I believe that it is being exported to the United States, and I earnestly recommend my professional brethren to avail themselves of its certain curative properties. It is not a disagreeable medicine to administer, and should be drunk with each meal.

The amount which I prescribe is a water-glassful, and it is to be taken three times daily.

I am, very truly yours,
A. W. Parsons, M.D.

City of Mexico, May 12, 1888.

[We believe that this substance has been used in this country, but not with the brilliant results claimed for it.—Ed.]

HAS A PERSON WHO IS NOT SUSCEPTIBLE TO VACCINIA IMMUNITY AGAINST SMALL-POX?

To the Editor of The Medical Record.

Sir: I would be greatly obliged to medical men who may be willing to furnish me with information concerning the following:

A. B—— has been vaccinated many times—once when an infant, again later, and several times after that, and before attaining the age of six years; again when seventeen years of age—at twenty-one, twenty-three, twenty-four, thirty-two, and thirty-four. *None of the vaccinations was successful.*

Now the question arises, is A. B—— secure against the poison of small-pox because he has not been able to have a successful vaccination, or is he entirely *unprotected*—just as one is who has never been vaccinated, and who can be successfully vaccinated?

I find a great difference of opinion on this subject among medical men, some affirming that if one cannot be successfully vaccinated they cannot contract small-pox. Others believe that unsuccessful vaccination merely demonstrates that the person is *unprotected*, and therefore liable upon exposure to contract variola vera.

Very truly yours,
W. Thornton Parker, M.D.

Newport, R. I., May 17, 1888.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 27 to June 16, 1888.

White, Robert H., Major and Surgeon. Will report to regimental commander, First Infantry, to accompany Headquarters Field Staff, Band, and Battalion of First Infantry to Santa Barbara, Cal., on or about June 15, 1888, to remain until about September 1, 1888. S. O. 25, Division of the Pacific, May 28, 1888.

Cowdrey, S. G., Captain and Assistant Surgeon. Ordered to accompany the troops of the Sixteenth Infantry from Fort Bliss, Tex., to Fort Douglas, U. T., as medical officer. Will return to his station upon the completion of said duty. S. O. 54, Department of Texas, May 19, 1888.

Appel, D. M., Captain and Assistant Surgeon. Upon arrival of Captain J. V. Lauderdale, Assistant Surgeon at Fort Davis, will proceed to Camp Pena Colorado, Tex., for temporary duty at that camp; and upon return of First Lieutenant H. S. T. Harris, Assistant Surgeon, to Camp Pena Colorado, Assistant Surgeon Appel will return to Fort Davis. S. O. 57, Department of Texas, May 28, 1888.

Kean, J. R., First Lieutenant and Assistant Surgeon. Will accompany Troop C, Ninth Cavalry, from Fort Robinson, Neb., to Fort DuChesne, Utah, and return with Troop B, Ninth Cavalry, to Fort Robinson. S. O. 39, Department of the Platte, May 19, 1888.

Morris, E. R., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 61, Department of Arizona, May 28, 1888.

Finley, James A., Captain and Assistant Surgeon. Granted leave of absence for six months on Surgeon's certificate of disability, with permission to leave the Division of the Missouri. S. O. 129, A. G. O., June 5, 1888.

Benham, Robert B., Captain and Assistant Surgeon. Is relieved from duty at Fort DuChesne, Utah, to take effect upon completion of the duty assigned him in Paragraph 2, S. O. 33, c. s., Department of the Platte, and will then proceed to Fort Laramie, Wyo., reporting to the commanding officer for duty at that post. S. O. 44, Department of the Platte, June 4, 1888.

Pilcher, James E., First Lieutenant and Assistant Surgeon. Detailed as member of Board of Medical Officers appointed by S. O. 108, A. G. O., May 10, 1888, to meet at United States Military Academy, West Point, N. Y., to examine candidates for admission to the Academy, etc., *vice* Major M. O'Reilly, Surgeon, relieved. S. O. 128, A. G. O., June 4, 1888.

CHERBONNIER, A. V., Captain and Medical Storekeeper. Granted leave of absence for four months, on Surgeon's certificate of disability. S. O. 133, A. G. O., June 9, 1888.

WATERS, WILLIAM E., Major and Surgeon. Granted leave of absence for twenty days, to take effect about June 15, 1888. S. O. 64, Department of Columbia, June 8, 1888.

DEWITT, CALVIN, Major and Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 52, Department of Dakota, June 9, 1888.

BIRMINGHAM, HENRY P., Captain and Assistant Surgeon. Granted leave of absence for one month. S. O. 117, Division of the Atlantic, June 11. 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 16, 1888.

MCMURTRIE, DANIEL, Surgeon. Detached from Naval Hospital, Yokohama, Japan, and return home.

GRAVATT, C. U., Surgeon. Detached from U. S. S. Michigan, and to Hospital, Yokohama.

EDGAR, JOHN M., Passed Assistant Surgeon. Ordered to the U. S. S. Michigan.

MACKIE, B. S., Surgeon. Ordered to the U. S. S. Ossipee.

PARKER, J. B., Surgeon. Detached from U. S. S. Ossipee, and wait orders.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 16, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	3	2
Scarlet fever	158	31
Cerebro-spinal meningitis	5	4
Measles	204	18
Diphtheria	162	38
Small-pox	2	5
Yellow fever	0	0
Cholera	0	0

AMERICAN ASSOCIATION FOR THE CURE OF INEBRIATES.—The American Association for the Cure of Inebriates held its semi-annual session in Brooklyn last Wednesday. Several papers were presented. One, by Dr. T. L. Wright, of Bellefontaine, O., on "Points touching the Medical Jurisprudence of Alcoholic Inebriety," referred in large detail to the physical, mental, and moral disabilities caused by alcoholic indulgence, and asserted that these were only the advance-guard of pernicious results. Dr. C. C. Fite, of Knoxville, Tenn., offered a paper on "The Prohibition Question from a Medico-legal Standpoint," in which he predicted that long before prohibition becomes general, the vital issue—the prevention and cure of drunkenness—will be reached by society regarding habitual indulgence in alcohol as a disease, and denying the right of any individual to further a tendency, hereditary or acquired, toward the inevitable physical and mental damage which excess in drinking involves, insisting that he shall be protected—and with him those who, otherwise, might inherit the baneful effects of his excess—by treating and caring for him as for the insane, or the victims of other disease. The paper was a logical, forceful plea for the need of to-day—proper asylums where the alcoholic inebriate can have that rational, scientific treatment his case demands. Dr. J. B. Mattison, of Brooklyn, read two papers, "The Ethics of Opium Habitués," and "Antifebrin, *vice* Opium, as an Anodyne." In the former he asserted that the popular idea that all men who use opium are liars is a mistaken one. He argued that the prevalent opinion—uncharitable and untrue—of an opium habitué being merely the victim of a vicious indulgence was a leading factor in his desire to shield himself from censure, and claimed that a more rational and right appreciation of the situation—regarding such patients, with certain exceptions, as creatures of conditions beyond control—would be most helpful against the protective temptation to untruth. Besides, a more liberal and correct opinion on this score would have an important bearing on their medico-legal status and treatment. In his second paper, Dr. Mattison referred to the recent triumphs of analytical chemistry in giving the profession such valuable hypnotics as amylen hydrate and sulphonal, and, noting the far reaching value of any drug that will take the place of opium—which, while so great a blessing, is so often a bane—expressed his belief that the new anodyne, antifebrin, was the richest addition of modern times to the therapeutics of pain.

UNRIPE ORANGES IN METRORRHAGIA.—Dr. Justino Valdés Castro, of Havana, mentions in a therapeutical note published in the *Crónica Médico-Quirúrgica* that, having heard Dr. del Valle some years ago recommend the use of unripe oranges, boiled in their skins and well sweetened, in metrorrhagia when independent of organic disease, he has since that time employed this simple remedy largely in his practice, with excellent results. Indeed, he finds it more efficacious than more powerful drugs.—*Lancet*.

TO DISTINGUISH BETWEEN HUMAN AND ANIMAL BLOOD.—According to Dr. Peset y Cevera, writing in a Spanish journal, if blood be mixed with a little bile, small crystals are formed which are of different shapes in different species of animals. In man they are right-angled prisms, in the horse cubes, in pigs rhomboids, in sheep rhomboidal plates, in dogs right-angled prisms very similar to those seen in human blood, and in chickens more or less regular cubes.

A SPANISH MAGISTRATE, shocked and exasperated by repeated food adulteration, has issued a proclamation, aflame with righteous wrath, that "all wines, groceries, and provisions which, upon analysis, are proved to be injurious to health, will be confiscated forthwith and distributed to the different charitable institutions."—*Ex.*

A TEST FOR SEWER-GAS.—Dip a piece of blotting-paper in a solution of acetate of lead, 1 part; in water, 8 parts. If any sewer-air containing sulphuretted gases be present in the room, the paper will quickly turn black. As, however, sewer-air often contains no sulphur compounds, the test is by no means an infallible one.

A DOUBLE MONSTER.—It is reported in the Madagascar *Times* that a woman in Antanariva has given birth to a female infant having one trunk and one head, but four eyes, four ears, four arms, four legs, two noses, and two mouths. The monster died when two days old, having in the meantime frightened its mother into convulsions.

ON SOME CURIOUS RELATIONS OF GASTRIC ULCER.—At a late meeting of the Medical Society of London (*The British Medical Journal*), Dr. Ord read the notes of the case of an unmarried woman, who was admitted into St. Thomas' Hospital in December, 1887, with symptoms of gastric ulcer and extreme anæmia. After her admission, certain heart symptoms which were noticed on her admission underwent further development. Dr. Ord gave the grounds of his diagnosis of peri- and endocarditis. There was no pyrexia, nor any history of rheumatic fever. The coexistence of systems of gastric ulcer with those of peri- and endocarditis had already been noted by

Dr. Ord in three cases, and a remark by Dr. Buzzard elsewhere, to the effect that acute rheumatism might be the result of irritation of the medulla, had deeply impressed him. When, therefore, the coincidence of the signs of gastric ulcer with those of cardiac inflammation had been observed in at least four cases, the occurrence appeared to be worthy of serious thought. Several explanations were forthcoming: 1. Was it possible that, in an anæmic person with oversensitive pneumogastric centres, gastric irritation, well known to be capable of producing cardiac disturbance, could be capable of producing cardiac lesion? 2. Could pneumogastric irritation be the common cause of gastric ulcer and cardiac inflammation, the pneumogastric irritation being determined by excitation proceeding from the uterine organs, in a person already anæmic and prone to active reflex disturbance? 3. Was it possible that both sets of symptoms might be disorders of nutrition arising out of anæmia? Anæmia was known to have as an association optic neuritis; might both the ulcer and the cardiac inflammation be disturbances of nutrition similar to optic neuritis? Dr. Ord quoted a case at present under his care, in which the signs of gastric ulcer, of cardiac inflammation, and of optic neuritis were present in conjunction with extreme anæmia. He also quoted a case recently under his care in which myocarditis had been observed *post mortem* as one of the associations of pernicious anæmia. On the whole, Dr. Ord was inclined to regard the curious combinations of lesions noticed as disturbances of nutrition consequent on anæmia.

A CASE OF SLOW PULSE.—Dr. Czarkowski reports the case of a boy, five years of age, who had a pulse of 32 to the minute. The slow action of the heart was thought to be due to cerebral anæmia, and under treatment directed toward this condition, the pulse ascended gradually to 60, beyond which it could not be made to rise.—*Medi'sinskoye Obozreniye.*

TREATMENT OF EPILEPSY WITH THE ACTUAL CAUTERY.—At the meeting of the Société Médicale des Hôpitaux, March 23, 1888, M. Charles Féré called attention to an epileptic patient now under his care whom he had treated by applications of the actual cautery to the scalp. M. Féré has treated ten patients in his adult epileptic ward at Bicêtre. All the patients presented hemiplegia; some were affected with Jacksonian epilepsy, others with the common form. M. Féré applied the actual cautery every two or three days to the parts corresponding to the psychomotor zones of the brain, so as to prevent the possibility of suppuration. The attacks were remarkably diminished in frequency and violence in the cases thus treated.—*British Medical Journal.*

THE HEREDITARY DEGENERATIVE INFLUENCE OF ALCOHOL.—At the meeting of the Académie des Sciences, on March 5th, MM. A. Mairet and Combemale related their observations on the degenerative hereditary influence of alcohol. Twelve puppies were born of a dog submitted to chronic intoxication with alcohol, and a young, healthy bitch with no defect. Two were stillborn, three died accidentally; the seven others succumbed to various diseases—epileptic attacks, verminous enteritis, pulmonary and peritoneal tuberculosis. At the necropsy lesions, evidently arising from alcoholic degeneration, were found—thickening of the bones of the skull, premature closing of fontanelles, adhesion of the dura mater to the cranial bones, difference in weight of the cerebral hemispheres, fatty degeneration of the liver. A strong, intelligent bitch, during the last three weeks of gestation, was intoxicated with absinthe, and gave birth to six puppies, of which three were stillborn; two were well developed physically, but were not at all intelligent; the third—a bitch X—grew slowly, presenting defective intelligence and a remarkable degree of anosmia. X presenting symptoms of degeneration, more especially of the nervous system, was coupled with a strong, intelligent dog. She gave birth to three puppies, one of which had flat foot, atrophy of several of the toes, wolf's mouth; a second died of marasmus; the third was attacked with atrophy of the hind legs. From the latter case it would appear that the degenerative influence of alcohol is greater in the second than in the first generation.—*British Medical Journal.*

QUACKERY AND THE RELIGIOUS PRESS.—At the last meeting of the State Medical Society of Arkansas, the following resolutions were passed:

Resolved, That the members of the State Medical Society of Arkansas have for years observed with pain and mortification the patronage given to charlatanism in all its multifarious aspects by the religious press of our country.

Resolved further, and most specifically, That the appearance in religious papers, ostensibly published for the inculcation of truth and morality, of serious homilies on prayer and praise side by side with cures for consumption, cancer, Bright's disease, and other incurable ailments, to which an editorial endorsement is often given, as well as secret preparations under the cloak of remedies for disease, but really intended for purposes of fœticide and other immoral uses, largely tends to shake the confidence of the profession of medicine in the integrity and purpose of the managers and editors of such journals.

Resolved, further, That it has been the well-known custom of the profession to render services gratuitously to clergymen, which we do not regret nor do we propose to recall; yet we must assert that the frequent occurrence of endorsements and recommendations by the clergy of peripatetic doctors and advertising charlatans has in many instances been the only reward of our gratuitous services.

Resolved, further, That we are aware that the editors of religious newspapers admit the painful situation in which these advertisments place them, and attempt to excuse themselves by saying that it is necessary to take these advertisements in order to obtain means to conduct their papers; but, in the language of orthodox theology, we would say: "Put behind you that damnable doctrine that we must do evil that good may come."

Resolved, further, That, as a Society, we declare that the continued perpetration of the above offences by some of the clergy and religious press brings harm to the bodies of their constituency, and damages materially their influence upon the thinking class of the medical profession.

FOR WINTER ITCH.—A correspondent from Texas writes that he can cure "winter itch" in every instance by the application of a very strong solution of corrosive sublimate. The solution should be nearly strong enough to produce vesication, and should be applied with a sponge, over an area of about three inches square, two or three times a day, a new portion of the skin being moistened each time.

BLINDNESS FOLLOWING A LIGHTNING STROKE.—Dr. Shishkin has reported to the Medical Society of the Caucasus a case of a boy of eleven years who was struck by lightning. It was noticed that his sight was affected afterward, and examination revealed the presence of a traumatic cataract.

SALT IN MILK FOR CHILDREN—Dr. Jacobi says that the physiological effect of chloride of sodium is very important, no matter whether it is directly introduced through the mother's milk or vegetable diet. Both of the latter contain more potassium than sodium, and neither ought ever to be given, to the well or sick, without the addition of table salt. A portion of that which is introduced may be absorbed in solution; another part is, however, broken up into another sodium salt and hydrochloric acid. Thus it serves directly as an excitant to the secretion of the glands and facilitates digestion. Therefore during diseases in which the secretion of gastric juice is interfered with, or in the beginning of convalescence, when both the secreting faculties and the muscular power of the stomach are wanting, and the necessity of resorting to nitrogenous food is apparent, an ample supply of salt ought to be furnished. The excess of acid which may get into the intestinal canal unites with the sodium of the bile in the duodenum, and assists in producing a second combination of chloride of sodium, which again is dissolved in the intestines and absorbed. Its action in the circulation is well understood; it enhances the vital processes, mainly by accelerating tissue changes through the elimination of more urea and carbonic acid. A very important fact is also this: that the addition of chloride of sodium prevents the solid coagulation of milk by either rennet or gastric-juice. The cow's milk ought never to be given without table salt, and the latter ought to be added to a woman's milk when it behaves like cow's milk in regard to solid curdling and consequent indigestibility. Habitual constipation of children is also influenced beneficially, for two reasons: not only is the food made more digestible, but the secretions of the alimentary canal, both serous and glandular, are made more effective by its presence.—*Archives of Pediatrics.*

Hot Baths for Insomnia.—In an article on the treatment of sleeplessness Dr. Eccles (*The Practitioner*) says that in attempting to overcome the partial functional activity of the brain, which appears to exist with and account for the dream-laden unrefreshing form of sleep, one has employed wet-packing, abdominal compresses, cold bathing, elevation of the head by means of extra pillows, and the application of warmth to the extremities by means of hot bottles or bags, with very variable, and, generally speaking, little success; but a hot bath, taken immediately before the time at which one wishes the patient to settle quietly for the night, has proved most valuable in producing a dreamless sleep, although not usually of longer duration than four hours without intermission, and sometimes followed by a period of great wakefulness, relieved only by a short morning doze; still even where this somewhat uncomfortable vigil supervenes, the patient always feels more refreshed and happier the next day than after a long night of uneasy dreaming sleep. To effect the permanent restoration of refreshing sleep a method of treatment is needed which must break the chain of vicious circumstances under whose thraldom the patient has lost the power to sleep. The brain, in these cases, often found to have been overworked, must be allowed to lie fallow as far as possible; the stomach, which has generally suffered with the other organs of digestion from the most extraordinary maltreatment, must be coaxed back again to a regular performance of its duties; while the muscular system, which has become wasted and inert from long disuse, must be called upon to fulfil its digestive and excrementitious functions, so long left in abeyance. Under the combined influence of the recumbent position in a quiet room, away from the cares of domestic, social, or business life, carefully modified diet, and massage applied as a therapeutical agent, not without regard to the mode, duration, and extent of its administration, the method of treatment referred to may be carried out with the happiest result in the majority of cases.

Acute Dilatation of the Stomach.—At a recent meeting of the Leeds and West Riding Medico-Chirurgical Society Mr. Jessop communicated the following case: The patient, a lady, aged twenty-six, had, a month before, undergone excision of the hip-joint for disease of seventeen years' duration, originating in distinct traumatism, and which Mr. Jessop believed to be non-tubercular. Her general health and her family history were remarkably good. At the operation the disease was found to be limited to the head of the femur, the section being made through healthy bone, and the acetabulum intact. The wound was nearly closed, and she was rapidly improving, when one day, in the absence of the nurse, she obtained an apple, the whole of which she ate greedily. She was shortly afterward seized with severe continuous vomiting. An aperient was administered, and she was put on milk diet. On the following two days the vomiting was intermittent, and was associated with extreme thirst. On the third day it was observed that before vomiting the abdomen was tumid, and the outline of the stomach, much distended, was clearly visible. After vomiting, the abdomen became flaccid, and nothing abnormal could be made out either as regards resonance, resistance, or tumor. There was no tenderness, but the extreme thirst continued, and the patient was obviously rapidly sinking. On the fourth day, as a last resource, the abdominal cavity was explored by the usual median incision, when the stomach, duodenum, and the first six inches of the jejunum were found enormously distended, the whole of the remainder of the intestines being remarkably collapsed and small. The stomach was opened by a small incision near the pyloric end, and a finger introduced. The pylorus could not be distinguished, owing to its extreme dilatation, a condition which also affected the duodenum as far as the finger could reach. The patient died in a few hours. At the necropsy nothing more could be made out. There was no mechanical obstruetion anywhere. The intestine simply seemed to pass from a condition of extreme dilatation to one of extreme contraction at a point six inches below the duodenum.—*The British Medical Journal.*

Antipyrin in Nocturnal Emissions.—According to the Vienna correspondent of the *British Medical Journal*, Dr. Thör, of Bucharest, has given some particulars as to the effect of antipyrin in cases of nocturnal emissions. Lupulin and camphor have been abandoned in such cases. Curschmann states that the sedative effect of lupulin on the genital organs, in spite of all recommendations, was not proved. As to camphor, it has, according to his opinion, no better effect. Fürbringer (*Krankheiten der Harn- und Geschlechtsorgane*) is of the same opinion. Zeissl still recommends it, as do Purgsz and other writers. The effect of nux vomica, arsenic, and atropine is also often uncertain. Among all the remedies hitherto employed, bromide of potassium or bromide of sodium was the most useful. Diday recommends it to the exclusion of every other drug. Bromide of potassium, from two to five grammes in a glass of water, taken just before going to bed, will, according to his experience, exert a prompt effect and check the pollutions. The prolonged use of the preparations of bromide, however, as is well known, produced an acne-like eruption, and the use of the remedy had, for this reason, often to be discontinued. Dr. Thör states that he has found antipyrin an excellent substitute for the bromides. He gives it in doses of from eight to fifteen, grains to be taken by the patient a short time before going to bed. In seven cases it had proved very successful, and checked the pollutions. No disagreeable after-effects were observed. In "neuro-asthenia sexualis," in the sense of Beard, antipyrin could also be used with good results; but the dose had in these cases to be sometimes increased from fifteen to thirty grains a day.

Anecdote of Darwin's Father.—The father of the great naturalist was a physician, of whom the following story is related in his life, written by his son: "When a very young man he was called to consult with the family physician in the case of a gentleman of much distinction in Shropshire. The old doctor told the wife that the illness was of such a nature that it must end fatally. Dr. Darwin took a different view, and maintained that the gentleman would recover. He died nevertheless. An autopsy proved the young doctor quite wrong in all respects, and he acknowledged his error. Naturally, he never expected to be consulted again by this family; but a few months later the widow sent for him, having dismissed the old family doctor. Greatly surprised, he asked a friend of the widow to find out how he had come to be consulted. The widow answered the friend that she would never again see the odious old doctor who said from the first that her husband would die, while Dr. Darwin always maintained that he would recover."

A CASE OF EXCISION OF A DISLOCATED SPLEEN, AND SUBSEQUENT EXPECTORATION OF THE LIGATURE OF THE PEDICLE.

By THEODORE A. McGRAW, M.D.,

DETROIT, MICH.

I RECORD the following case because I think that it is unique in medical literature.

Mrs. A. B——, of Windsor, Ontario, aged forty, came to my office in May, 1887, to consult me in regard to a tumor in the lower part and right side of the abdomen. As a child she had been healthy, and had suffered no serious illness until she was seventeen years of age, when she had a sharp attack of pneumonia. She did not, however, remember which side had been affected. She was married at the age of twenty, and had never borne any children. In 1870 she and her husband moved to Arkansas, and she there developed a malarial cachexia, and for two years suffered continually from malarial fever. During that time she had not noticed any enlargement in the region of the spleen, but had been troubled with a general bloating of the abdomen. As this was associated with complete suppression of the menses, she supposed herself to be pregnant, until, on her removal to Texas, in 1872, the bloating disappeared and the menses returned. In 1875 the couple went to London, Ontario, and obtained employment in the Insane Asylum. In 1876 she received a kick in the abdomen from an insane woman, from the effects of which she suffered a severe inflammation of the bowels, which confined her to bed for a period of three weeks. After recovering from the immediate effects of this injury she noticed a fulness in the lower part of the abdomen. She began also to suffer attacks of pain in the region of the right ovary. Her menstruation soon afterward became irregular, and a period ensued, of seven months' duration, in which the courses were altogether absent. She thought that she was pregnant and fancied that she could feel life. This belief was corroborated by the continuous growth of the abdominl swelling, which occupied from the first the right hypogastric region. This tumor was at first movable, and could be pushed across the median line to the left, and then caused *less* pain than when in its usual position. After each attack of colicky pain the tumor seemed to grow in size. At the end of seven months the menses returned, the paroxysmal attacks of pain ceased, and the tumor ceased to grow. From 1877 to 1886 she suffered but little inconvenience from the now stationary tumor. During all of this time her menses were regular. In 1886 she began again to suffer severe paroxysms of pain in the right hypogastric region, which finally cost her so much suffering as to make her determined to seek relief at any risk. When I first saw her she was somewhat anæmic and debilitated, and her skin had a slightly yellowish hue. There was a tumor of semi-solid consistency in the right hypogastric region, which filled the whole iliac fossa and extended about an inch over the median line to the left. Its upper margin was about an inch below a transverse line carried through the navel. It pressed the uterus and bladder far to the left, and filled up the right side of the true pelvis to within two inches of the outlet. It seemed attached to, and yet distinct from, the uterus, and had the feel of a tumor of semi-solid character lodged in the right broad ligament. The tumor was quite immovable, not yielding to pressure made by the surgeon, nor changing its position with that of the patient. The uterus was two and one-half inches in depth and lay far to the left. The urine was normal.

She entered St. Mary's Hospital on June 27, 1887. On June 28th I operated upon her, assisted by Drs. C. Henri Leonard, John Boice, William M. Donald, J. Henry Carstens, W. E. Clark, and Charles Davidson, all of Detroit. An exploratory incision two inches long, midway between the navel and pubes, enabled me to determine the fact that the soft pulpy tumor under my finger was not cystic, and that it was not attached to the uterus or ovary. Enlarging the incision and passing the hand down under the tumor, I found that it was nowhere adherent, and that it had been rendered immovable by the pressure of neighboring organs, as it lay wedged in between the bones of the pelvis and the other pelvic contents. As soon as it could be brought fairly into light, it was evident that the tumor was an enlarged and dislocated spleen with a very long pedicle. Turning it out on to the abdomen, I transfixed its pedicle with a needle armed with stout braided and aseptic silk, taking great care not to injure any of the immense blood-vessels which coursed to and from the tumor. The veins were especially large and numerous; some of them seemed as large as the little finger, and a previous experience in a like operation had taught me that they were thin-walled and very friable. The thread had been rendered aseptic by first boiling in a solution of bichloride of mercury, one to a thousand, and afterward boiling in clear water. They were taken out of the boiling water just before using. I tied first one-half of the transfixed pedicle, and then passing the needle back through the same opening, I tied the other half, and finally passed the ligature around the whole pedicle and tied it again. Immediately after the ligation one of the great veins became so enormously swollen that I feared it would burst. It became as large as a small hen's egg, and only collapsed when the pedicle had been cut and returned to the abdomen. It is probable that the position of the spleen on the outer abdominal wall caused some kinking in the pedicle, which prevented the free return of blood from the veins, and that the obstacle was removed by the retraction of the cut pedicle. The operation was finished by cleansing the abdomen and suturing the wound with silver wire. Every precaution had been taken to keep the abdominal cavity free from all septic taint. Immediately after its removal the spleen and its contained blood were found to weigh something over forty-six ounces. During the first week there was no rise of temperature, and the patient showed no bad symptoms excepting nausea and pain in the left shoulder.

Throughout the entire illness there was neither tympanites nor abdominal tenderness. On July 4th, however, there was discovered quite an amount of albumen in her urine. Her menses made their appearance a week too soon, on July 5th. On July 6th the sutures were removed, and the wound was found to have healed nearly, but not quite, by first intention. At two places there was a superficial suppuration. On the evening of July 10th the temperature suddenly rose to 100.5° F., and she began to complain of pain in the left side, just below the ribs. The pain in the left shoulder, which had been persistent ever since the operation, grew worse. On auscultation slight friction-sounds were heard at the base of the left lung.

For the next five days the temperature varied from 99° F. in the morning, to 100.5° in the evening. On the 15th the symptoms became suddenly aggravated, crepitant râles were heard in the base of the left lung, and the lower part of the lung evinced dulness on percussion. Patient had a dry hacking cough, without expectoration. During all this time the abdomen was quite free from pain and tenderness, except at a point just beneath the ribs on the left side, where pain could be produced by deep pressure. The symptoms gradually increased in severity. On the afternoon of the 18th her temperature rose to 102.5° F., and on July 25th reached its highest mark of 103° F. The pleuro-pneumonia involved, finally, the whole of the lower lobe, and was accompanied in its later stage with a profuse gray tenacious secretion. After July 25th the symptoms gradually subsided, but it was not until August 7th that the temperature fell to normal. She then became convalescent, and when she left the hospital, on August 13th, the lung had completely recovered, her appetite had returned, the albumen had disappeared from her urine, and only one troublesome symptom remained, and that was a persistent pain in front of the left shoulder, just above and outside of the coracoid process. On leaving the hospital the patient went to her home in Windsor, whence she came at intervals of three or four weeks to visit me at my office.

For a time she seemed to grow better, and even the pain in the shoulder gave less cause for complaint. In the course of three or four months, however, she began to complain of weakness, loss of appetite, and great irritability of temper, and a hacking cough and pain in the left side made me fearful lest some trouble were developing as a sequel to the old pneumonia. For a long time, however, there were no physical symptoms to corroborate this apprehension. On November 28th, after having lost sight of her for a time, I was called to see her in Windsor, on account of an abdominal swelling which had made its appearance rather suddenly at the side of the wound, and found to my chagrin that the scar had given way, and she had a large ventral hernia. For this I applied a truss, which has answered its purpose, and relieved that particular inconvenience; but, at the same time, I satisfied myself that she was failing in health, without being able to discover any organic lesion to account for it. In March, 1888, she began to suffer again in the left side, at a level corresponding to the base of the lung, and her cough became more pronounced. I could not find any dulness on percussion, but the lower part of the lung was filled with moist râles. On March 27th she came to my office in alarm, on account of an hæmoptysis. She had that morning coughed up several mouthfuls of bright-red blood. This spitting of blood continued until April 1st, when she had an unusually severe paroxysm of coughing, and finally expectorated a ligature, which could be no other than that with which I had tied the pedicle. I had used for that purpose a medium size of braided silk, and, as I have related, without cutting the silk I had tied the pedicle with three knots. I had first passed the needle through the pedicle and tied one half, and then again through the same opening to tie the other half, and finally passed it around the whole pedicle and fastened it with a secure knot. All this was, of course, unknown to the patient. The ligature which she brought to show me had three loops in it, fastened with three knots, two small loops and one large one, and the thread was the same braided surgeon's silk.

There could be no question of deception on the part of the patient, and the only possible doubt was whether it had been expectorated or vomited. I have myself no doubt of the correctness of her own statement that it had come from the lungs. She had had no symptoms whatever referable to the stomach, and had not suffered nausea since she had recovered from the effects of the chloroform. A ligature discharged into the stomach without causing any sensation of nausea would naturally pass down through the alimentary canal. I see no reason, therefore, to doubt her positive statement that the ligature was ejected by coughing. Almost immediately after the expulsion of the thread she began to get better. The moist râles could no longer be heard in the lungs, the cough ceased, and the pain in the shoulder vanished. Some of the improvement might, of course, be attributed to the mental effect produced by the event, but there can be little doubt that her system experienced an immediate benefit from the relief of a chronic irritation in a tissue so important as that of the lung. When examining the case before the operation, the position and shape of the tumor, so different from the splenic tumors I had seen, were such that I was completely misled in diagnosis. It never occurred to me that the tumor might be an enlarged spleen. I have not since then been able to find a case recorded in which the dislocation was so great as in this. I did not, therefore, examine the blood at all before the operation. For many days afterward the patient was exceedingly sensitive and irritable, and when I went to her with the view of getting a drop of her blood for microscopic examination, she made such a clamorous protest that I was obliged to desist. It was not until August 12th, and then against her will, that I accomplished the purpose. I then, and several times afterward, examined her blood, carefully comparing it with my own and other healthy persons'. For several months after the operation, whether as the result of the operation or the original disease, the number of white blood-corpuscles was considerably increased, the blood usually containing five or six times as many, in proportion to the red, as healthy blood.

During the last three months this disproportion has gradually disappeared, and the proportion of white to red corpuscles has become normal. In remarking upon the case, I will say, first of all, regarding the diagnosis, that I do not believe it could have been positively made out even though the true nature of the case had been suspected. The tumor was so jammed into the pelvis that its notched edge could not be felt. Its shape was round, rather than long and oval, and, as the normal spleen cannot always be certainly detected in its proper position, it would not have been possible to diagnosticate with absolute precision its absence from its proper position. I did not come to a positive decision as regards diagnosis, and the operation was at first exploratory. The opinion which seemed to me most plausible was that the case was one of old incapsuled extra-uterine pregnancy. The symptoms which pointed in this direction were the cessation of the menstruation for seven months and the simultaneous growth of the tumor, the occurrence of frequent colicky pains, the return of the menses and the simultaneous cessation of the growth of the tumor, the feeling of life, the long quiescence of the growth, then the tendency of the pain, when it recurred in 1886, to come chiefly at the menstrual period, and, finally, the consistency of the tumor.

My theory of the case is as follows: She contracted a malarial fever in Arkansas, and probably, as a result of the chronic malarial poisoning, her spleen became enlarged and dislocated downward by reason of its weight. During the struggle with the insane woman she received a kick directly on the top of the enlarged organ with such force as to completely rupture its ligaments and force it downward to the right. The weight of the organ, sustained only by its blood-vessels and the connective tissue which surrounded them, served still further to depress the tumor, until it finally became too firmly wedged in the right side of the pelvis to be easily moved. The interference with its blood-supply, or perhaps more with the return of its blood through the veins, caused by its abnormal position and surroundings, had the effect of causing still greater congestion and enlargement, and the pressure on the ovaries made the vascular disturbance more noticeable at the period of menstruation. It is difficult to explain the long period from 1877 to 1886 of comparative freedom from pain and trouble. Possibly the ovary may have assumed a position in which it escaped pressure, and the return of the pain may have been the result of a fall of the ovary between the tumor and the pelvic wall. The pleuro-pneumonia was the result, apparently, of a chill which she received by lying uncovered in the oppressively hot nights, which made life at that time a burden to everyone in the city. The diaphragmatic pleura was first affected and the lung became secondarily involved after a considerable interval. It cannot be assumed that these organs were secondarily involved by a process which began in the pedicle and extended through the diaphragm. The normal temperature of the patient on the days preceding the first onset of the pleural inflammation, the entire freedom of the abdomen from pain and tenderness, excepting only where the diaphragm could be made susceptible to pressure, and the brevity of time occupied by the whole course of the disease, combine to shut out that hypothesis. As the result of this inflammation the two pleural layers became glued together. The pedicle retracted immediately after the operation, and probably lodged above the intestines and liver, against the diaphragm. We may assume that the ligature became adherent to the diaphragm, and that, when the pedicle had sufficiently shrunk, the movements of respiration had gradually detached the thread from the remains of the blood-vessels which it had constricted. The pressure of the knot on the diaphragm caused an absorption of tissue, and the constant contraction and relaxation of fibre undoubtedly aided in working the thread through the muscle, pleura. and finally lung. The ligature came away as perfect as when it was put in. and the absence of all softening and erosion was an additional proof that its expulsion was to be ascribed to a process of absorption rather than of suppuration and abscess. The pain in the shoulder was probably due to the irritation of the phrenic nerve, conducted on to the communicating branch of the fifth cervical, or possibly on to the subclavian branch of the brachial plexus, which also communicates with the phrenic. It has completely ceased since the expulsion of the ligature.

The case is still too recent to have much weight in determining the question of the propriety of extirpating "ague cakes" which are intractable to treatment. It has been my fortune to see several cases in which death resulted from no other ascertainable cause than a malarial spleen. Whether such patients would do better without their diseased organs, is one of those problems which the after-histories of such cases as this will have to solve. I will say in conclusion that this is my second splenectomy. The first was performed on a man by the name of Charles S——, aged twenty-seven years, on May 24, 1881, on account of an enormous splenic tumor which filled up the abdomen to such an extent as to make breathing difficult, and to obliterate all those natural boundaries by which, on percussion, we determine the size and position of organs. Although the case did not promise much, yet the patient was so urgent for an operation, on account of his continual suffering, that I ventured to perform it. I did so in the presence and with the aid of Drs. Eugene Smith, Chapaton, Richards, Shurley, Boice, and others. I found the spleen enormously enlarged, and adherent both to the abdominal parietes and to the diaphragm. The separation of the spleen from the diaphragm was followed by great and persistent hemorrhage. When, finally, the tumor was lifted out on to the abdomen, and a ligature was passed through the pedicle and around each half of it, a vein in the pedicle was ruptured, and could only be secured by tying the pedicle a second time lower down.

The patient died two and a half hours after the operation. The immediate cause of death was the bleeding from the diaphragm, which could not be controlled. The liver, however, was found to be also much enlarged, and, like the spleen, the subject of waxy degeneration. The tumor weighed, after the loss of all of its contained blood, over nineteen pounds.

The German Public Health Society will hold its fourteenth meeting in Frankfort-on-the-Main on September 13 to 16, 1888.

TERPINE IN DISEASES OF THE LUNGS.[1]

By D. M. CAMMANN, M.D.,

NEW YORK.

Mr. Chairman and Gentlemen: Lately several drugs belonging to the group of the terebinthinates have been used in medicine with a more or less favorable result. Among them are terebene, terebinthene, terpine, and terpinol. Their effects are similar in a general way to those of turpentine, with individual differences in their action, or the relative amount of their action on various organs of the body. It is my purpose in this brief paper to consider the use of terpine in diseases of the lungs.

Terpine is a crystalline hydrate of the oil of turpentine. Crystals similar,[2] if not identical in character, have been found in the interior of an old pine-log, where they were, probably formed from the oil deposited in the wood. If oil of turpentine be allowed to stand for some time freely exposed to the air and to moisture, crystals of terpine will be deposited on the sides of the vessel. It is colorless, odorless, and almost tasteless, insoluble in water, soluble in alcohol, and melts at 100° C. It was first prescribed as an expectorant by Lépine,[3] of Lyons, who calls it "the best expectorant in existence." Its use in bronchial affections has been favorably mentioned by Vigier, Jeannel, Sée, and Boyland. New drugs are apt to be received with enthusiasm, to run a brief course, and then to drop out of use. Terpine has not escaped the usual fate at the outset of its career, but that it is a drug that deserves a permanent place seems probable. During the past year I have frequently used terpine in my class at the Demilt Dispensary and elsewhere, and a careful record of a number of cases has been kept by Dr. F. N. Patterson. I will give short histories of a few of the cases, and a synopsis of the rest:

Case I. *Bronchitis with pleuritic adhesions.*—Mrs. L——, aged forty, January 19, 1888. Family history good. The middle of December caught cold in the head and chest. Has had pain between the shoulders ever since. Very little cough; slight expectoration; some dyspnœa.

Physical examination: On percussion raised pitch under left clavicle, and on auscultation harsh respiration. In infrascapular regions harsh respiration, and coarse, dry superficial râles. ℞. Pil. terpin., gr. iv., q.i.d.

January 28th.—Coughed less. For three or four days spat up more, but since then less than at first. Dyspnœa much less; urine increased; a full feeling in the head after taking the pills; appetite improved.

February 2d.—Cough and dyspnœa less; expectoration less and thinner; urine increased.

Case II. *Bronchitis with pleuritic adhesions.*—B. L——, aged forty-five, hod-carrier, March 19, 1888. Family history good. Has had fistula in ano for ten years. Has had cough for ten years, but it was never troublesome until this winter, when he has had a feeling of tightness across the chest and fits of coughing with little expectoration. Three or four weeks ago he spat up some blood; has had dyspnœa; no night-sweats. Has lost twenty pounds in weight. In 1869 and 1870, and again in 1881, had chills and fever; none since. Present condition: Has dyspnœa; coughs for about fifteen minutes in the morning on rising; expectoration thick, white, and in considerable quantity; is anæmic; bowels regular; appetite poor.

Physical examination: Dulness on percussion under both clavicles, most marked under the left. Respiration feeble over both lungs in front, except at outer third of left infraclavicular region, where expiration is harsh; harsh expiration in right suprascapular region; feeble respiration over remainder of both lungs behind; coarse, dry. superficial râles over both lungs behind, especially over the left, and most abundant at left apex. ℞. Terpine, gr. iv., q.i.d.

---

[2] Wood & Bache: New York Dispensatory.

[3] Bul. Gén. de Thérapeutique and Journal de Thérapeutique for 1886.

March 22d.—Cough and dyspnœa less; expectoration the same in quantity and consistence, but comes easier; urine increased; appetite the same.

March 24th.—Has improved since last time.

CASE III. *Pleurisy.*—Miss M. L——, aged twenty-two, dress-maker. February 28, 1888. Family history good. Was well until one year ago; has had slight cough since. Says she has had night-sweats at times for past two weeks. Has a good deal of dyspnœa on exertion; no pain in the chest; has never spit any blood; has headache every afternoon. Nausea after eating. Is anæmic.

Physical examination: A shower of subcrepitant râles at the base of the right lung in front with each inspiration; a few subcrepitant râles at right base behind; coarse râles at left base behind; cog-wheel respiration under right clavicle at the beginning of the examination, but it disappeared before she went away. ℞. Terpine, gr. iv., q.i.d.

March 3d.—Cough the same; expectoration less and thinner; urine not increased.

March 10th.—Cough less; expectoration less and thinner; dyspnœa the same.

March 24.—Coughs only a little in the morning; expectoration less and thinner; dyspnœa less.

CASE IV. *Phthisis pulmonalis.*—J. K——, aged forty-three, miner, February 21, 1888. Family history good. He served for three years during the war, at which time he had typhoid fever. Was well until thirteen months ago; since then has had cough and shortness of breath. Had hæmoptysis three months ago. Has had night-sweats for twelve months, but not constantly.

Physical examination: Dulness on percussion at left base in front; harsh respiration over right lung in front; expiration prolonged under the clavicle; under the left clavicle harsh respiration; coarse râles over both sides in front; bronchial breathing and bronchophony at base of left lung behind. ℞. Terpine, gr. iv., q.i.d.

February 25th.—Cough and dyspnœa less; expectoration the same in amount, but thinner; urine not increased.

March 1st.—Thinks he has caught fresh cold and does not feel as well. The cough is less, but dyspnœa and expectoration about the same as before. Has been vomiting, but does not think it is due to the medicine.

An analysis of twenty-five cases shows that nineteen were cases of bronchitis, most of them chronic, some of long standing, with extensive pleuritic adhesions. Four cases were of phthisis, one of pleurisy, and one of emphysema. The shortest time that any of these cases were under treatment was two days, the longest time nine weeks. The average length of treatment was seventeen days. From four to eight grains of the terpine were given in pills, usually four times daily. Most of the cases took four grains four times daily, without any other drug. Twenty-four of the cases were improved, most of them markedly, and two only slightly. One case was unimproved. This was a case of bronchitis that had lasted a month, and four grains of the terpine were given three times daily for five days. The expectoration became thinner, but no other change was apparent. The cough was lessened in all the cases except the one just mentioned. In twenty of the twenty-five cases the expectoration was markedly diminished; in four it was not diminished, and in one it was increased. In several cases it was increased for the first day or two, and afterward decreased. The cases in which the expectoration is recorded as not diminished, and the one in which it was increased, were under observation only five or six days, and it is probable that if they had been treated longer a diminution might have been recorded in all. In eighteen it was thinner, becoming more watery and less purulent; in six it was no thinner. Of the cases that were troubled with dyspnœa the dyspnœa was diminished in sixteen; it was undiminished in three. The patients noticed an increase in the urine in eleven cases; in eleven cases no increase was noticed. In some of the cases the appetite improved; in one case slight nausea, and in another fulness of the head were experienced after taking the pills.

The mode of action of turpentine and its derivations needs further investigation. That they are cardiac stimulants has been asserted, probably on insufficient evidence. The experiments of Nothnagel and Rossbach[1] indicate that oil of turpentine in all cases diminishes the blood-pressure, and to a very slight degree, or not at all, the number of cardiac pulsations. Whether they enter into the circulation unchanged is uncertain. Whether the peroxide of hydrogen, which some of the terebinthinates, in common with many other substances, are capable of generating and then absorbing,[2] plays an important part in their action is a subject for further study. I have only endeavored in this paper to record a few facts, and to avoid theoretical explanations, which may be found in abundance in many books.

THE CHOLERA IN CHILI.

By JOHN TRUMBULL, M.D.,

VALPARAISO, CHILI.

THE subject of the cholera in Chili is one which, possessing a measure of interest for every medical man, becomes peculiarly interesting when regarded as a possible forerunner of the introduction of the disease into the United States. From Chili it will in all probability follow the line of travel up the western coast to Panama, from which point there will be two avenues of approach and danger—the Pacific and Atlantic seaboards, besides the Mexican frontier, which might possibly threaten later on. The disease has already obtained a foothold in some of the northern ports and towns of Chili (whither the boom in copper carried large numbers of miners and prospecters), and steadily advances northward, though its advance in that direction is not as rapid as in a southerly direction along the railroad lines. For the present we are cut off from Peru; but her isolated position, for the yellow fever in Panama and Guayaquil has led her to close also against vessels from the north, will compel a surrender. Even now she has had to admit a couple of steamers carrying coals from Southern Chili, and pretty soon the demand for wheat, etc., will force her to open her ports. And could this be overcome, still concealment and prevarication will doubtless lead to the resumption of travel long before the epidemic is stamped out. Were she able to interrupt all commercial relations with Chili, it would be an easy matter to check the march of the epidemic; but that is impossible, and, given steamer travel, I have not faith in the ability to check its entry into Peru or Central America. A quarantine that is one in reality, effective and unremitting, may then save from such a visitation, whereas a complete interruption of travel and business will certainly do so; yet, to the profit of general business, and steamer companies in particular, the health, happiness, and lives of thousands are sacrificed.

What has been the cost to Chili of failure in this regard? The loss by sickness, death, and interruption to work, estimated financially, together with the expenses of maintaining dispensaries, sanitary stations, and lazarettes, though social questions of importance, are not to be considered, for, as physicians, we are interested rather in what pertains to health and life. The registration of deaths is very faulty, in that the law allows a burial permit on certificate of death made out by a doctor, a justice of peace, or any person, accompanied by two witnesses. This last not only makes possible the perpetration and concealment of crime, but renders statistics almost worthless. Such friends almost invariably give as cause of death, "fever," or, now that cholera means, for the poor, burial in a common pit, "indigestion." Such causes tend to make the published statistics fall far below the mark, yet the official reports are serious enough. For instance: In Santiago, the capital, a city of 180,000 inhabitants, the first case occurred January 14, 1887, and within eleven weeks the lazarettes and ambulances alone had 6,279 cases of cholera, with 3,481 deaths; a mortality of fifty-five per cent., or a proportion of 19.3 deaths per 1,000 of population. The more probable figures would raise this to 28 per 1,000; and this is what the topography of Santiago, with its heat, abundance of water running all over the city in open water-ways of slight declivity, absence of other sewerage, and use of these waters for irrigation and even domestic purposes, would lead us to expect. Regarding the country as a whole, while last summer the disease did not extend outside of the Aconcagua Valley and along the railroad lines from Santiago south, or here, yet the official statistics for 1887, which only include a few days of this present epidemic, place the deaths from cholera at 22,000, or one per cent. of the entire population of the country.

---

[1] Materia Medica, Trans., p. 492. New York, 1884.

[2] Day: Lancet, August 17, 1878.

During the first epidemic Valparaiso escaped rather easily, owing in part to the efficient measures taken, the improvements in sewerage, removal of garbage, etc., but principally because of the extreme dryness of the place. The past winter the rainfall was three times the amount of our average yearly fall, and, as a consequence, there is running water even now in the "quebradas," or ravines, which separate the hills on which the town is built. Besides, the numberless little wells in these ravines, so much used by washerwomen or watermen, have offered every chance for the spread of the disease through the sections supplied by these waters.

For the lower portions of the city the drinking-water comes from a deep well, sunk in the middle of a sandy valley, six miles out of town, which offers small chance of contamination; and it is this portion of the city that has had least sickness, whereas the residents on the hills have suffered greatly. December 5, 1887, a case of cholera was recorded, a couple of days later another, and so a few scattered cases appeared till the 15th, when a general epidemic was declared. After a fortnight, in which 522 deaths were recorded, it began to decline; though every Tuesday and Wednesday there has been a periodical rise in the number of new cases and deaths, due to the drinking and excesses which mark the mode of observance of the Sabbath by the common people. The civil registry offices give the following deaths as from cholera: Second half of December, 522; January, 569; first half of February, 158; total, 1,249; equal to one per cent. of our population.

While referring to statistics, it may be worth noting that during 1887 there were in Valparaiso 4,492 births, as against 6,456 deaths.

Throughout the entire country the cases this year have been more virulent, and the newly infected districts and towns have suffered greatly. The papers to-day state that in a township in the South, having a population of 1,500, the number of deaths caused by the epidemic have amounted to 616. In the Northern parts and mining towns it is very severe. Some days, out of 25 new cases, 20 prove fatal within twenty-four hours; and often whole families have been carried off.

The same is true of general practice. In my own private practice of 18 cases attended, I have lost 13, or seventy-two per cent. Of those 13, 11 lived, on an average, only fifteen hours from the very first symptoms noted, and these had medical attention, on an average, only seven hours after the first diarrhœa. The recoveries were first seen six hours from the commencement of the symptoms, so that recovery cannot be properly attributed to prompter attendance, but rather to a milder type of disease.

Not only of a more fatal type, but of an entirely different character, has the disease been. Last year many of the fatal cases had sanguinolent discharges; in others, vomiting was abundant, diarrhœa profuse, and cramps very severe. This year I have noticed less vomiting and diarrhœa, little pain from cramps in the extremities, but, on the other hand, epigastric pain, cardiac distress and oppression, profuse sweating, rapid and feeble, or imperceptible pulse, the case quickly developing the symptoms of profound collapse—coldness, lividity, aphonia, dyspnœa, and stupor.

With reference to treatment one must of necessity refer to the prevalence of bowel troubles which often make it hard to decide whether the symptoms are those of beginning cholera or not; and in view of such, one cannot but regret the general resort to opiates, and protest against the publishing of prescriptions, and indiscriminate dosing by Tom, Dick, and Harry, who tell us of their wonderful cures of cholera, but never know the harm they sometimes work. It is my plan to palpate and percuss the abdomen in every case of diarrhœa, and principally by such examination am I guided as to the use of opiates and astringents, or evacuants to be followed by them. If fulness or dulness show the presence of fecal matter, a purge is given, oil preferably, with a previous powder of calomel should the tongue be loaded and dirty; then opiates, acids, astringents, carminatives, etc., separately or in combination, as the case may require. The presence or absence of pain in this diarrhœa is of diagnostic value, a simple diarrhœa from indigestion often beginning with pain, whereas the diarrhœa unattended by pain merits suspicion; and of the numberless cases coming with abdominal pain and diarrhœa, because they feared they had cholera, in not one had I cause to regret assuring them to the contrary and treating them as indicated. The orthodox treatment with the native physicians is calomel, two grains, every one or two hours, in all stages of the disease. The reason of their treatment is theoretical, and based on the good results which follow its use in appropriate cases of simple diarrhœa.

In the first stage of the actual disease, if vomiting and diarrhœa are not very frequent or discharges profuse, and pulse of good strength, the drinking of hot infusions of aromatic herbs, camomile, with or without coca leaves, will in mild cases relieve the epigastric distress, check vomiting and diarrhœa, and aid in producing reaction. If more pronounced, opium and acids, as laudanum with acid arom. sulph., or opium, camphor, capsicum, and chloroform are of good service; while yet if discharges are profuse, morphine, and atropine in powder (tablet triturates are always handy), are given by mouth when retained or by subcutaneous injection when the vomiting is persistent.

If the heart begin to flag, caffeine and ether, subcutaneously or by the mouth; alcoholics, ether, or strophanthus with ether, have all been tried and proved serviceable; though when failure of circulation begins to manifest itself, the endeavor should be to try and establish reaction by external warmth and copious injections of hot liquids, one-half per cent. solutions of tannin or salicylic acid, or hot tea with brandy or ether. Last year the prevailing method was the injection of four or five litres of fluid to try and force the ileo-cæcal valve, wash and disinfect the small intestine, using solutions of tannin, hyposulphite of soda, salicylic acid, or even corrosive sublimate; but at present the more rational procedure holds, viz., to try and wash out the lower bowel, if evacuations are frequent and annoying. The temperature of the water, or solution, is from 38° to 42° C., and a litre of such fluid is injected. These failing, or in a case demanding more energetic measures, a large subcutaneous injection of a saline solution should be made. The following powders I have used, dissolved in one litre of warm water:

Sodæ chloridi	5.00 gm.
Sodæ phosph	0.30 "
Potass. chloridi	0.40 "
Sodæ carb	1.20 "

M. Ft. pulv.

The fluid is preferably thrown into the subcutaneous tissue in the lumbar region. In women as much as 750 c.c. can be injected in one spot, though usually 500 c.c. are enough for one place to receive, and as much more should then be injected on the other side. It is surprising how rapidly absorption takes place, and how certain it is to improve the condition of the patient, restore the pulse and voice, and relieve in every way. The benefit, however, is in too many cases only temporary, for the pulse again fails and then a second hypodermoclysis fails to cause such marked improvement; or, the pulse having gained steadily, reaction is set up, but goes on to a typhoidal state with high temperature, which generally terminates in death in the cases that called for this treatment. In the fulminating cases—cold, cyanotic, pulseless, shrunken, breathing with difficulty, and groaning with the pain in the back and shoulders—chloroform is a boon.

With pregnant women part of the treatment requires serious consideration of the question of interference with the course of gestation. The fœtus generally dies, but often the condition of the mother, even when reaction has set in, prevents one from removing it; and then when failure sets in with the typhoidal state, one is tempted to remove the dead fœtus for fear it may be the occasion of the general condition. The prognosis, where pregnancy complicates, is almost fatal. I have not heard of a recovery in such. In ordinary cases, the pulse I take to be of greatest prognostic value. If the pulse is of fair strength and not very rapid, the prognosis is good, reaction is probable, and recovery possible; while, if the pulse be feeble and rapid—130 to 150—or imperceptible, reaction is possible, but recovery is improbable.

Clinical Department.

THE DISASTROUS RESULTS OF A NEW ARTIFICIAL DRUM MEMBRANE.[1]

By FRANK W. RING, M.D.,

NEW YORK.

THE above title of the report of this case is misleading, but it would otherwise have been necessary to have extended it to undue length. Miss X—— consulted me June 14, 1887, in regard to poor vision. Complained of seeing less well with the left eye. I examined them both, and gave her a pair of cylindrics. During the conversation relative to the visit, I mentioned the fact that, as she was apparently deaf, I had better look at her ears. The lady was very much embarrassed at my suggestion, and remarked that there were reasons why she would prefer I should not examine them. My curiosity being excited, I at last elicited from her the following history:

She could not remember, from childhood, ever having heard as others, but was obliged to listen intently and watch the expression of those conversing with her. She became exceedingly sensitive, impressible, and despondent. Would shun society and associate only with her most intimate friends. It was at this time, when about twenty years of age, in 1879, that she chanced to meet a retired army surgeon, who was kind enough to assure her that all she needed was a new drum, and he highly recommended *larding pork*, which the young lady immediately began to use in this wise: She would get from the butcher a piece of salt pork for larding, cut a portion sufficient to fill the external auditory canal, and plug it. At first it was removed every few days, but after a few years of constant use it would not be necessary to change it oftener than once a week. She was confident she heard better. The difference was apparent immediately the pork was removed. And when I first saw her, June 14, 1887, she was continuing in her usual manner, changing the new drums once a week, but did not hear as well as formerly. I was extremely anxious to look into auditory canals which had been packed with larding pork for eight consecutive years, and upon representing to her the great danger she was incurring from the practice, she afforded me an opportunity of examining them the next day.

I found a suppuration of both middle ears, extending to the external meati. Both canals were filled with pus, detritus, and cheesy matter. The mucous membrane was raised in folds, like a washer-woman's fingers. The membranæ tympani were almost entirely destroyed, a ring-like edge only existing. The inferior extremity of the handle of the malleus was exposed in both ears. In the right the watch was heard at one inch; left, one-half of an inch. Right aërial conduction, nine seconds; left aërial conduction, five seconds; right bone conduction, fifteen seconds; left bone conduction, thirteen seconds. I only saw the patient twice at this period, as she immediately went away for the summer. It was with reluctance she discontinued the use of the pork—as her hearing was undoubtedly decreased without it. I gave her proper directions in regard to treatment during her absence, and did not see her again until September 15th, when the hearing distance was reduced to contact in the right, and one half-fortieths in the left. There was a discharge from both ears, no modification in the membranes, redness and swelling of adjacent parts.

After constant treatment from September 15th to December 3d, the left membrane closed with several cicatrices adherent to the inner wall of the tympanic cavity. During the final cicatrization of this membrane the patient had severe pain in the ear, located in the meatus and tragus. Hearing distance, contact with watch, the 24th of this month (December). The right membrane had healed by extensive cicatrices, adherent in several places to the inner tympanic wall. She had severe pain for several days during this period, so that I applied a blister to the mastoid, and hot-water injections to the canal, which gave her relief.

The suppuration in the left ear ceased December 3d, and there has been no further treatment applied to it, except inflation; but in the right a persistent oozing continued up to March 1st. I had exhausted all remedies in the pharmacopœia, including antiseptic, alcoholic, astringent, and caustic treatment, boracic acid, nitrate of silver from five to sixty grains to the ounce, peroxide of hydrogen, and merely cleanliness, until one day I was telling Dr. F. M. Wilson of my tribulations, and he suggested bichloride of mercury in solution. So I instructed the patient to lie down at stated intervals, for an hour at a time, and keep the ear filled with a one to four thousand solution of the drug mentioned. And in three weeks all signs of discharge had ceased.

The patient now hears better than she ever did before. By the watch, the right is $\frac{6}{40}$, the left $\frac{5}{40}$. Conversation easily heard near by, but not well at a distance. I think the history of this case goes to show the wonderful recuperative power of the ears, after a persistent abuse of their functions for a period of eight years. There may have been other instances of similar conditions, but I have been unable to find them.

THE DEATH OF CLEOPATRA.—Dr. Viaud Grand-Marais, of Nantes, has been holding an inquest on the sudden death of Cleopatra. He rejects the theory that her death was caused by the bite of a viper. She was accustomed to test the effects of various poisons on her slaves, in order to ascertain which caused the easiest death. Having shown that no viper was found in the room of the fair suicide, that her body presented no traces of bites, and that her two maid-servants were found dead or dying at the foot of her bed, he comes to the conclusion that her death was caused by carbonic oxide. —*Bulletin Général de Thérapeutique*, No. 14 1888.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY
WM. WOOD & Co., Nos. 56 and 58 Lafayette Place.

New York, June 30, 1888.

EXPLORATORY CATHETERIZATION OF THE MALE URETER.

THE surgeon not rarely meets cases of pyelitis or destructive renal disorder in which he is puzzled to know with certainty which kidney is affected; or having found the diseased kidney, he may feel a doubt whether the patient has another one.

In order to settle these questions positively, it is necessary either to make an exploratory laparotomy, or to introduce a catheter into one of the ureters, and draw off the urine secreted by a single kidney. The expedient of compressing one ureter by means of instruments introduced into the bladder or rectum, has not been very satisfactory, and the catheterization of the ureter *via* the urethra is only possible in the female. The introduction of cystoscopes hardly helps the matter in the case of the male.

The well-known surgeon, Dr. Axel Iversen, of Copenhagen, describes in the *Centralblatt für Chirurgie*, April 21, 1888, a case in which he successfully catheterized the male ureters by means of a supra-pubic incision into the bladder.

The patient was an adult, who for some time had suffered from evidences of purulent inflammation of a kidney. No signs or symptoms were present, however, to tell with certainty which organ was affected. The bladder being opened by an epicystotomy after the method of Guyon, an electric light was introduced, and the ureters successfully catheterized. From the right was drawn off a fluid containing some blood-cells and casts, but no pus; from the left almost pure pus was obtained.

The wound healed without any trouble, and the diagnosis was made. Unfortunately the knowledge did not greatly profit the patient, except perhaps in preventing an experimental operation. The right kidney was thought to be too seriously diseased to justify nephrectomy or nephrotomy on the left. Dr. Iversen considers the exploratory epicystotomy perfectly safe, and believes that in some cases it may be of the most essential service in directing the work of the surgeon.

ACETONURIA IN CHILDREN.

THE presence of acetone in the urine has until quite lately been thought to indicate a serious pathological change. It had been observed most often in connection with diabetes, and in the later stages of that disease when coma was impending or present. Jaksch, Penzoldt, and others, however, have shown that acetonuria may occur in comparatively normal states; and Baginski has, in particular, studied this normal acetonuria in children (*La France Médicale*, August 20, 1887).

Baginski finds that acetonuria is very common in the febrile affections of childhood, and its amount is usually related to the intensity of the fever. His observations led him to believe that the acetone is in some way related to the decomposition of nitrogenous food, or to the action of such food upon the metabolism of the tissues. This is in accordance with the clinical fact that acetonuria in diabetics is most apt to develop when a pure meat diet has been studiously adhered to.

Baginski denies and disproves the theory of Jaksch, that acetone is formed in the process of lactic acid fermentation due to digestive disorder; for, on washing out the fermenting contents of the stomach, he found no trace of acetone.

The same observer states that acetone does not produce convulsive symptoms, and that it is not the result of chloral given in eclampsia, nor of the asphyxia of that state.

Exactly where and how acetone is formed is still unknown, but the fact that it often occurs in the urine of children, both during febrile and afebrile states, is one which the clinician should bear in mind. It leads to this practical deduction that the child is getting too much animal food.

THE PATHOLOGY OF PURPURA HÆMORRHAGICA.

THE pathology of purpura in its various forms furnishes a most obscure and puzzling problem. Naturally a great many classifications and theories of the disease have been put forward, and it has even been asserted that no such disease exists, purpuric spots being only a symptom of a dozen or more different conditions.

Leaving out, however, the manifestly symptomatic purpura of phosphorus and other poisons, of scurvy, ulcerative endocarditis, hæmophilia, and certain acute infectious fevers, we have remaining a disease which seems to be idiopathic, and which shows itself essentially in three forms, viz., that of purpura simplex, purpura hæmorrhagica of Werlhoff, and purpura rheumatica. These various types are not sharply divided from each other, and it is quite conceivable that they are the expressions of the same pathogenic agent.

It would be impossible that in this microbic age a microbe should not be found and looked upon as the existing cause. Such is in truth the case. M. Balzer has found micrococci in the blood of purpuric patients during life, and Petrone, Cheyne, Wickham Legg, Rebi Ceci, and Hlava have also all met with micro-organisms in the disease.

Unfortunately, the micro-organism has not always been the same, and the attempts heretofore made to study its life-history have not been very satisfactory.

Quite recently, M. Martin de Gimard (Thèse de Paris, 1888, *L'Union Médicale*, 1888, p. 683) has studied the subject from the bacteriological and clinical standpoint anew, and has obtained results that are apparently definite and conclusive.

M. Gimard observed twelve cases of purpura occurring in the Children's Hospital at Paris, under Professor Grancher. The disease appeared almost like an epidemic, so that there could be little doubt that all the patients suffered from the same disorder. Yet the types varied considerably, from the gangrenous or fulminating form described by Charron and Henoch, to the milder types resembling purpura simplex; some cases were pyretic, resembling the "angio-hæmatic" typhoid of M. Mathieu.

Gimard believes that his cases were illustrations of a primary infectious purpura, and he infers that true purpura is always a primary infectious disease.

He found a micrococcus in the blood during life, and the same micrococcus in the purpuric spots after death. These micrococci, taken from the living blood, were cultivated in different media and always found to possess the same characters. Cultures of these micro-organisms were injected beneath the skin, into the serous cavities and blood of guinea-pigs, with the result of producing hemorrhagic effusions in various parts of the animal. M. Gimard found that at the centre of the hemorrhagic spots there was an accumulation of micro-organisms, with consequent stasis and inflammatory changes, resulting in injury of the vessel-walls and sanguineous effusion.

If we accept the results of Gimard's studies, purpura hæmorrhagica is a primary infectious disease of microbic origin, and shows itself in types of varying severity.

LATIN IN PRESCRIPTIONS.

We hear occasionally some violent denunciations of the use of Latin in prescription-writing.

It is old-fashioned, a relic of mediævalism, the Latin employed is bad, and its employment in any event is useless; the doctor writes his prescriptions in Latin so as to conceal something from the patient and make a mystery of his art.

Such are the stock arguments against writing prescriptions in Latin. But none of them, we venture to say, should have any serious weight at present. If physicians write bad Latin, let the schools teach them better. It is only a matter of a few weeks' diligent study to master enough of this language for medical use.

There is no serious objection to the use of the Latin in prescriptions, while there is objection to English, or French, or German. Medicine is a cosmopolitan science, and its progress depends upon the united work of physicians in all nationalities. If each nation wrote its therapeutic treatises without the use of Latin, the difficulties of understanding and mastering foreign work would be much increased.

This is already very evident to those who read French medical literature and attempt to read French prescriptions. Many French physicians follow the new-fashioned plan and use French in prescription-writing. An illustration of the results of this method may be seen in a prescription taken at random from the popular French journal *L'Union Médicale*. It is called a *vin tonique*:

℞. Extrait de feuilles de noyer........ 30.
Phosphate de soude................ 15.
Vin de Malaga....................1,000.
M.

The first constituent one may find, after searching, to be walnut leaves; but whether *Juglans nigra*, or *J. cinerea*, or *J. fraxinifolia*, or *J. regia*, no one but the writer of the modernized prescription knows.

If the prescription has been written in Latin, according to the rules of our art, it would have been intelligible at once to French, Greek, German, or American, for it would have been written, for example:

℞. Extract. fol. juglant. nigræ.
Sodii phosphat., etc.

The study of French therapeutical literature is thus made unnecessarily difficult and inexact by the adoption of the vernacular in prescriptions, and it would be a serious retrogression if English, German, and other races each followed the French example.

STERILIZED MILK AS A FOOD.

In the April number of our esteemed contemporary *The Dietetic Gazette* is an article by Dr. A. Caille upon the mode of preparing sterilized milk for the use of infants. The fact that milk just as it comes from the breast of woman or the udder of the cow is aseptic, makes it *a priori* reasonable to believe that aseptic milk is the most natural and healthful form to use. The readiness with which milk becomes impregnated with germs and undergoes fermentation is well known. To rid it entirely of these germs, Dr. Soxhlet, of Munich, has devised a sterilizing apparatus which is easily used, comparatively inexpensive, and has been, we are told, extensively introduced into households at Munich. This apparatus consists essentially of a number of small (five-ounce) glass bottles, with rubber and glass stoppers combined. There is a tray for holding these, fitting in a tin pot for boiling the milk. The milk is raised to a boiling-point in the small bottles; these are then hermetically closed and kept at 212° F. for twenty minutes, when the milk is sterilized. The process is really, therefore, only one of prolonged boiling under pressure. Dr. Caille made a numbei of experiments with milk sterilized in Soxhlet's apparatus, and with milk boiled in the ordinary way. Results, as stated, were:

1. Milk sterilized in Soxhlet's apparatus, boiled thirty minutes, remained good eighteen days.

2. Milk boiled in small bottles for fifteen minutes; before removing from the boiling water the bottle was closed with a pledget of cotton. This milk remained good five days.

3. Milk boiled in small bottles for fifteen minutes; then taken from the water, and each bottle closed with a tight, non-perforated rubber stopper. This milk remained good five days.

4. Milk boiled in small bottles for fifteen minutes; then taken from the water and each bottle immediately closed with a good quality cork stopper. This milk remained good five days.

5. Milk boiled in a pot, and put into small bottles after cooling and closed with a cork stopper. Sour after four days.

6. Milk boiled in a pot, and put into small bottles after cooling and closed with non-perforated rubber stopper. Sour after four days. [This milk was kept in a spare room with temperature ranging from 50° to 70° F.]

7. Milk boiled in a pot in the usual manner, and left standing in an open dish in a room with a temperature of 75° F.: (*a*) ordinary store-milk had a distinct sour taste

and smell after *eight hours;* (*b*) good "bottle-milk" "turned" after fifteen hours.

8. Milk boiled in a pot in the usual manner and placed in the ice-box in an open dish: (*a*) ordinary store-milk "turned" after eighteen hours; good bottle-milk "turned" after twenty-six hours.

Dr. Caille further concludes that:

The boiling of milk for twenty to thirty minutes under slight pressure, in small bottles hermetically closed, is all that is necessary to practically carry out the principle involved in sterilization; *i.e.*, to destroy the germs of fermentation.

The essential materials are, small bottles with Soxhlet's stoppers and a tray.

Milk boiled in small bottles for twenty minutes and immediately closed by rubber, cork, or cotton stoppers, will keep sweet, if put on ice, for several days.

The boiling of milk in the ordinary way is faulty. All milk for infants' and children's use should be boiled in small bottles in a water-bath for twenty minutes, when it will keep much longer than if boiled in the ordinary way and the usual length of time.

The transportation of milk should take place in refrigerator-cars during the summer months. This should be secured by legal enactment.

The indications for the use of sterilized milk are believed to be the following:

1. Sterilized milk should be administered to all children deprived of the breast.

2. It may be given to children suffering from diarrhœa or convalescent from cholera infantum, when milk boiled in the ordinary way is not tolerated.

3. A supply of sterilized milk is of the utmost importance for children while travelling.

The fact that sterilized milk is sure not to ferment for a considerable period of time must recommend it strongly. On the other hand, it is believed by some that boiled milk has lost some of its more delicate properties as a food.; and as between fresh milk and sterilized milk, we think that no one will hesitate to prefer the former.

THE HEMI-LATERALITY OF RHEUMATISM.

THE theory that acute articular rheumatism has a nervous origin is an old one; and, although not yet accepted, there are, not infrequently, striking observations reported which show at least a close relation between the nervous centres and rheumatic manifestations. Some two years ago Dr. Cazalis made a communication to the Paris Académie de Médecine in which he asserted that in two-thirds of the cases of ordinary chronic rheumatism it was found that the manifestations, during a large part of the course of the disease, were mainly on one side of the body, and oftener on the right. He also asserted that the pulmonary and pleuritic complications of acute rheumatism were oftener on the right side. He further called attention to a symptom of chronic rheumatism which, he says, is little known, viz., a deformity of the great toe; and he asserted that this predominates on the side of the hemi-rheumatism.

The same author has recently cited two cases (*L'Union Médicale*) which still further support his view of the tendency of rheumatism to hemi-laterality. One of these was a patient of Professor Verneuil, who suffered for a long time from that peculiar form of rheumatism known as multiple ephemeral periostitis. During the whole course of the malady, which lasted several years, the shifting pains and nodes continued to be upon the right side. The patient was finally cured by an anti-rheumatic treatment.

The second is a case of a woman who during several years had manifestations of rheumatism only upon the left side.

The view of Dr. Cazalis is that rheumatism, like chorea and hysteria, has a tendency to develop chiefly on one side.; and this tendency is thought to be an important evidence of the dominating influence of the nervous system on the development of rheumatic symptoms.

News of the Week.

PROFESSOR WILLIAM H. WELCH delivered an address on medicine before the Yale Medical Society on June 26th.

DR. EGBERT H. GRANDIN has resigned from the Department of Gynecology at the New York Polyclinic.

AN INTERNATIONAL CONGRESS OF DERMATOLOGY AND SYPHILOGRAPHY is to be held in Paris, August 15 to 22, 1889. At this time will occur the official inauguration of the new Museum of the Hospital St. Louis.

THE VERMONT STATE MEDICAL SOCIETY holds its semi-annual meeting at St. Alban's, Vt., June 28th and 29th.

A COLLEGE WHOSE DIPLOMAS ARE SIGNED BY THE PRESIDENT OF THE UNITED STATES.—Professor Austin Flint says that there is a medical college [in Washington] which recently graduated a class of one: "This college has seven professors, one demonstrator, and one lecturer. For the convenience of students occupied in other pursuits during the day, all the lectures are given in the evening. The college requires a matriculating examination, and has a 'graded course' of three years. It is the medical department of a university, and, in addition to the clinical and other advantages enjoyed by its students, the diplomas from this school are signed by the President of the United States."

UNDER THE FOSTERING influence of the ethical rules laid down by the American Medical Association, there is growing in the West a practice of physicians advertising themselves as specialists in the medical journals. One gentleman who edits a journal takes half a page in his own and other journals to announce that he is professor of diseases of the mind and nervous system, with various peculiar qualifications for treating such diseases. "Terms reasonable—reduced rates, if necessary."

QUARANTINE AT SAN FRANCISCO.—The *Pacific Medical and Surgical Journal* says: "San Francisco claims a population of more than 300,000, and boasts of being the leading city of the Pacific coast of America. Its quarantine establishment consists of a steam-tugboat and one medical officer, now temporarily supplemented by an assistant, for whose compensation there is no legal provision! No apparatus for disinfection nor accommodation for people under detention has been provided, for the law-making powers have furnished no means. In their absence, the steamship companies employ hired vessels anchored in the bay, where these persons, sometimes numbering hundreds, are maintained at heavy expense, estimated at about $150,000 for the months of February, March, and April."

The American Neurological Association will hold its next annual session at Washington, September 18, 19, and 20, 1888. There will be discussions on "The Relation of Renal Diseases to Diseases of the Nervous System," "Cases of Trauma, with well-defined Lesions of the Central Nervous System," and on "Muscular Dystrophies." The following papers will also be read: "Post-hemiplegic Disturbances of Motion in Children," by Philip C. Knapp, M.D., of Boston; "Heat Centres in Man," by Isaac Ott, M.D., of Easton; "The 'Ape-fissure,' so called, in Man," by Burt G. Wilder, M.D., of Ithaca; "Clinical Report of Cases of Epilepsy following Cerebral Hemiplegia," by E. D. Fisher, M.D., of New York; "The Relation of Urinary Changes to Functional Nervous Diseases," by C. L. Dana, M.D., of New York; "The Differential Diagnosis between General Paresis, certain forms of Intracranial Syphilis, and the Cerebral Type of Disseminated Sclerosis," by Landon Carter Gray, M.D., of New York; "Report of a Case of Primary Lateral Sclerosis, with late Cerebral Symptoms, due to Cyst of the Floor of the Lateral Ventricle, with Microscopic Report," by Wharton Sinkler, M.D., of Philadelphia; "A Case of an Unusual Form of Myxœdema, illustrated by Photographs and Sections of Excised Tissues," by F. X. Dercum, M.D., of Philadelphia; "A Case of Alcoholic Multiple Neuritis, with Sections," by James Hendrie Lloyd, M.D., of Philadelphia; "Observations and Experiments respecting the Pathology of Neuritis," by James J. Putnam, M.D., of Boston. Dr. C. K. Mills and others will demonstrate specimens. "Myositis Subacuta Progressiva," by George W. Jacoby, M.D., of New York; "The Differential Diagnosis between Peripheral Neuritis and those Cerebral Affections with which it is most likely to be Confounded," by E. C. Spitzka, M.D., of New York; "Nervous Affections following Injury," by Philip C. Knapp, M.D., of Boston; "Hereditary Chorea," by Wharton Sinkler, M.D., of Philadelphia; "Aneurism of an Anomalous Artery causing Antero-posterior Division of the Optic Chiasm and Bitemporal Hemianopsia," by S. Weir Mitchell, M.D., of Philadelphia. To be read by F. X. Dercum, of Philadelphia, "A Case of Focal Epilepsy with Observations on Trephining," by James Hendrie Lloyd, M.D., of Philadelphia. The preliminary report of the Committee on Encephalic Nomenclature will be read by Burt G. Wilder, M.D., Chairman, of Ithaca.

James J. Putnam, M.D., *President*,
106 Marlboro Street, Boston, Mass.
Græme M. Hammond, M.D., *Secretary*,
58 West Forty-fifth Street, New York.

An Association of Undertakers held its annual meeting at Philadelphia recently. They were addressed by Dr. Joseph F. Edwards of the State Board of Health, who, we are told, created some consternation by asserting that the rising generation would make a nation of sanitarians.

"The American Dermatologist" is the name of a new journal published monthly at Indianapolis, and edited by Dr. Ralph J. Perry.

The "Schweninger" Treatment for Obesity is, as most physicians know, a treatment stolen by a quack, Schweninger, from the distinguished physician Oertel. It consists in a rigid limitation as to the amount and quality of the food, and the abstinence from water at meals. We are pleased to learn from the public press that Dr. J. W. Gibbs, a graduate of the Eclectic Medical College, and a politician, "was the man who brought the Schweninger system here, having gone over to Germany for the purpose of getting it, and purchased the knowledge of it from the originator."

Dr. Evander M. Ranney, of this city, died on June 22d, aged seventy-eight. Dr. Ranney was born in Vermont, and was a son of Lieutenant-Governor Ranney of that State. He was the eldest of a family of thirteen children, and one of the six of Lieutenant-Governor Ranney's sons who chose medicine for a profession. Two are still practising in this city.

Modern Electrical Science, in developing electrical lights and electric motors has also brought for consideration new problems in regard to the safety of human life. The electric arc lamps are supplied by currents of one or two thousand volts, and these are dangerous to life. It seems that in order to use milder currents which are effective, larger and more expensive cables are necessary. Hence it is, to some extent, the greed of money which makes electric lights dangerous. Very much the same thing can be said, probably, of electric motors. The cars run by storage batteries cannot be considered as at all dangerous.

The Kansas City Hospital College of Medicine, which, the *Kansas City Medical Index* says, was "the most disreputable medical college in the United States," after a period of apparent desuetude has been turned into a "pure homœopathic institution."

Narrow Escape of a Physician from Poisoning by a Cobra.—Dr. Vincent Richards, of Calcutta, an enthusiastic investigator in many different lines of medical research, had a narrow escape recently from poisoning by a cobra bite. He was holding a vigorous cobra in his right hand for the purpose of obtaining its venom. In pointing with his left forefinger to where some watch-glasses lay, he brought the part close to the animal's head. The snake made a sudden dart, and fastened its fangs just below the second joint. Retaining his presence of mind, Dr. Richards tore the reptile away and killed it. A tight ligature was at once placed on the proximal aspect of the wounds, which were sucked, enlarged by knife, allowed to bleed freely, and thoroughly mopped with a five per cent. solution of permanganate of potash; an India-rubber cord was bound around the wrist. A medical friend subsequently further enlarged the wounds, and applied strong nitric acid to them. The ligatures were cautiously removed after a time. No symptom of poisoning resulted except a slight tightness of breathing.

Vacation of Societies.—The various medical societies of New York take their usual recesses for two months.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, March 28, 1888.

W. P. Northrup, M.D., President, in the Chair.

Dr. Eugene Hodenpyle presented a specimen of

EPITHELIOMA OF THE ŒSOPHAGUS,

with perforation into the posterior mediastinum, gangrene of the right lung, and acute pericarditis.

F. S——, aged thirty-six. Family and previous history negative. The patient stated that up to four weeks before his admission he was in good health. At that time he began to have difficulty in swallowing, and attempts to swallow solid food were frequently followed by regurgitation. When first seen he was able to swallow liquid food only, but a full-size bougie was passed into the stomach without detecting an obstruction. He rapidly became very much emaciated. The dysphagia became more and more marked, so that toward the close of the disease it was almost complete. Two days before his death it was noticed that the patient's breath was extremely offensive, and the presence of fluid in the right pleural cavity was made out. He died, January 27th, about two months after the first symptoms of his disease were noticed.

Autopsy.—The left lung was emphysematous, and the right lung had but two lobes. The pulmonary pleura was covered by a layer of dirty yellow fibrin, and in the pleural cavity there was about one quart of greenish-yellow serum, while at the base of the lung was a sacculated accumulation of clear serum. The lower lobe was consolidated, of a grayish-brown color, and granular on the cut surface. The upper lobe was collapsed. At the hilus of the lung was seen a large irregular cavity, with ragged edges, filled with a very offensive black fluid.

The pericardial sack contained two ounces of bloody serum, and both surfaces of the pericardium were coated with a thin layer of fibrin. The heart was otherwise normal.

At the cardiac end of the œsophagus was a large, raised, ulcerated mass, four inches in length, two inches and a half in width, and three-fourths of an inch in thickness.

It contained a slit-like perforation at its centre communicating with the posterior mediastinum. The calibre of the œsophagus was but little, if at all, constricted by the new-growth. In the posterior mediastinum the bronchial glands were enlarged and softened, and the surrounding structures were partially gangrenous.

Microscopical examination of the new-growth showed it to be an epithelioma containing a number of giant cells. The pneumonic area of the lung showed necrotic changes in places.

Dr. Hodenpyle also presented some specimens removed from the body of a man who was supposed to have been suffering from

PSEUDO-LEUKÆMIA.

The patient was sixty-two years of age. He was admitted into St. Francis Hospital on January 31, 1888, with a history of repeated attacks, during several years past, of diarrhœa, each attack lasting usually from one to three weeks. He had also had chronic bronchitis. He denied excessive drinking, and had never had rheumatism or malarial fever.

On admission to hospital he was examined for evidences of syphilis, with negative results. The inguinal, cervical, and epitrochlear glands were considerably enlarged and somewhat tender. The patient said that five weeks before his admission he had an attack of diarrhœa which had lasted up to the present time. He was now having about twenty loose passages a day, accompanied by some rectal tenesmus. Three weeks later his feet and legs became swollen. When first seen he was greatly emaciated and somewhat jaundiced. He complained of pain all over the abdomen, which was considerably distended with gas. No fluid was detected in it. The area of splenic dulness was increased. The liver was normal in size. The lungs showed lesions of general emphysema and bronchitis. The heart was normal. The urine contained albumen and casts. Pulse, 90 and small; respiration, 24; temperature, 99° F. Appetite good. No vomiting.

The patient became more and more emaciated, and finally died of pneumonia on February 16th.

Autopsy, eighteen hours after death. Lungs: There were slight adhesions of both lungs to the costal pleura, and one quart of clear serum was found in the left pleural cavity. On the pleura of both lungs were numerous white pin-head patches, not elevated and mostly in the centre of pigmented portions (multiple fibromata?). Lungs emphysematous, œdematous, and congested posteriorly; bronchi thickened and filled with muco-purulent fluid. There was little fluid in the pericardial sac. The heart-muscle was pale and flabby; the aorta was atheromatous.

There was no fluid in the abdominal cavity. The liver was somewhat enlarged, pale, and friable, and on cut section showed irregular yellowish-white, coarser, and finer mottling, and narrow irregular, whitish streaks.

The spleen was 16 ctm. long, 8 ctm. wide, and 7 ctm. thick; its surface roughened by patches of perisplenitis. The organ was hard, dark red in color, mottled with small irregular, whitish streaks and spots, and showed several dense, white, hard, irregular, wedge-shaped masses presenting the appearance of white infarctions. Some of these infarctions were red in the periphery and some were of reddish color throughout.

The pancreas was enlarged and hard.

The kidneys were of normal size and consistence. The left contained a small cyst. Cortex slightly thickened. Markings indistinct. Capsules adherent.

The supra-renal capsules were hard.

The solitary glands of the stomach, especially those about the pylorus, were swollen, and near this orifice was a soft tumor about two centimetres in diameter. The small intestine contained swollen solitary follicles and Peyer's patches.

In the large intestine, the solitary follicles were seen to be considerably swollen, the centres being depressed and blackened. Scattered about in the mucous membrane were a large number of spheroidal or more or less irregular nodules, occasionally pedunculated, varying from one-half c.c. to two or three c.c. in size.

The mesenteric glands were enlarged and soft.

Behind the peritoneum and surrounding, but not involving, the great vessels, was a large, hard, yellowish-white mass, extending from almost up to the diaphragm above into the pelvis below, where it had partially surrounded the sigmoid flexure of the colon, which was displaced toward the middle line.

The bladder was normal.

Microscopical examination.—The masses in the large intestine and those behind the peritoneum and in the stomach had essentially the same structure, being composed of large numbers of small spheroidal cells closely packed in a scanty connective-tissue reticulum, blood-vessels, etc. The enlarged mesenteric glands showed the lesions of hyperplasia.

The kidneys showed chronic diffuse nephritis, and the blood-vessels were partially filled with spheroidal cells.

The liver was thickly studded with masses similar in appearance to the tissue in the tumors of the intestine. Around the masses the liver-cells were flattened, pigmented, and fatty. The blood-vessels contained numbers of spheroidal cells. A similar condition was seen in the supra-renal capsules and the tissues surrounding them.

The spleen showed the usual appearances of white and red infarctions. There were enlarged Malpighian bodies and a great overcrowding of the cavernous veins with small spheroidal cells.

Dr. Prudden remarked upon the number and unusual size of the tumors in the large intestine. It was not known in this instance whether there was any increase in the number of the white blood-cells or not, and it could not be determined, therefore, with certainty whether the case was one of leukæmia or of pseudo-leukæmia.

Dr. Mendelson asked whether the spheroidal cells referred to were white blood-corpuscles or not.

Dr. Hodenpyle thought that they were.

Dr. H. M. Biggs presented a number of specimens illustrating

DISEASES OF THE CÆCUM AND VERMIFORM APPENDIX.

The first specimen was from a case of general peritonitis, following

SLOUGHING OF THE TIP OF THE VERMIFORM APPENDIX,

with the following history: The patient, a young man about thirty-three years of age, was seized at night with vomiting and diarrhœa, attended by marked abdominal pain. He had been well before this time. The physician who was called to see him supposed he had to deal with an ordinary case of gastro-enteritis, and treated him accordingly. Although he temporarily improved, he soon grew worse, the vomiting continued, and finally became fecal in character. Dr. Bryant was asked to see the case in consultation with Dr. Charles Simmons, the physician then in charge. At that time the abdomen was tensely distended and tympanitic. Patient had only a moderate elevation of temperature, a rather rapid pulse, fecal vomiting, and severe pain referred to the epigastrium. The tenderness was not very marked and was not localized. A diagnosis of general peritonitis, due probably to perforation of the vermiform, was made. The patient gradually sank and died.

At the autopsy a general peritonitis was found, with great matting together of the coils of intestines and considerable thick fibrino-purulent exudation. Scattered here and there between the coils of intestines were found numerous small pockets of pus. After a very careful search, the stump of the vermiform was found with its end sloughed off. In the peritoneal cavity was a small hard, fecal mass, which had evidently been the cause of the trouble. There was no apparent attempt at the incapsulation of the exudation around the cæcum or localization of the process. The vermiform projected from the inner side of the cæcum freely into the peritoneal cavity.

The second case, seen with Dr. L. M. Yale, was also one of vermiform sloughing, with

FECAL MASSES IN THE PERITONEUM.

The main points in the history were as follows: A boy, sixteen years of age, came home from school feeling unwell, and remained at home for this reason. He was first seen February 4th, but was taken sick two or three days before, at night, with severe abdominal pain. When first seen he had some elevation of temperature, abdominal tenderness, and slight tympanites. There were exaggerated nervous symptoms present at this time that rendered an immediate absolute diagnosis impossible. The patient was again seen at 6 P.M. on the same day, and a diagnosis of general peritonitis, probably following vermiform perforation, was made. Dr. Janeway saw him the same evening, and agreed with the diagnosis. There was no localized pain or tenderness. Dr. Sands saw the boy the following day, and made the same diagnosis. Patient died five days later. There was occasional vomiting during the sickness. Toward the end all abdominal tenderness disappeared.

At the autopsy, a general peritonitis was found. The coils of intestines were firmly matted together, and a moderate amount of fibrino-purulent exudation was found in the peritoneal cavity. The last four inches of the vermiform had sloughed off and lay loosely in the peritoneal cavity. This contained three small hard, fecal masses.

Lying near it in the abdominal cavity was another large hard, fecal mass, that had apparently been situated at the point of sloughing. The vermiform had evidently extended freely downward and inward. There was no apparent attempt at a localization of the process.

Dr. Biggs then presented a third specimen, showing

PERFORATION OF THE VERMIFORM APPENDIX.

The case was seen with Dr. W. T. Jenkins, Deputy Coroner. The death was reported by the physician in charge as having resulted from general peritonitis following the production of abortion. There was no history of an abortion, but the symptoms and condition aroused the suspicions of the physician in charge. The patient was a servant-girl, aged twenty-five. She was suddenly seized with severe abdominal pain during her menstrual period. The physician who was called to see her made a diagnosis of general peritonitis, and, from the presence of metrorrhagia, the fact that the girl was unmarried, and some evidence of a circumstantial character, concluded that the case was one of criminal abortion, and he so reported it to the Health Board. The autopsy revealed the presence of general peritonitis resulting from perforation of the vermiform appendix. A small mass of hard fecal matter was found in the peritoneal cavity. The vermiform extended freely out into the peritoneal cavity, and the point of ulceration, which was about one and a half inch from its origin, was only partially covered by peritoneal exudation.

Another specimen shown was one of a

LONG VERMIFORM APPENDIX,

measuring nearly nine inches in the fresh condition. It arose just below the ilio-cæcal valve, passed directly upward behind the iliac mesentery, being extra-peritoneal until just above the beginning of the mesentery, when it became intra-peritoneal, and continued its course up inside of the ascending colon as far as the under-surface of the liver, when it turned forward, lying underneath the liver.

In the next specimen there was

OBLITERATION OF THE OPENING OF THE VERMIFORM

just at its origin. Following this, an accumulation of the secretion from the mucous membrane lining occurred and produced an enormous dilatation. In the fresh condition it was considerably more than an inch in diameter and about four inches in length. There were no symptoms (so far as known) during life resulting from this condition.

The next specimen was one of

PERITYPHLITIS WITH PERFORATION INTO THE ASCENDING COLON.

The clinical history of the case was rather obscure. It was supposed to be a case of psoas abscess for some time. Pus was passed by the bowel. At the autopsy there was found a large abscess-cavity extending far up along the ascending colon and displacing it to the left, with extensive induration in the connective tissue. After a careful search, a communication between the cavity and the ascending colon was discovered. This was situated just below the pelvis of the right kidney.

Dr. Biggs then reported another case,

RUPTURE OF THE RECTUM,

the specimen of which he was unable to present at the time. The patient had suffered for a long time with symptoms of intestinal obstruction, supposed to be due to stricture situated at the upper portion of the rectum, or in the sigmoid flexure. Patient had not had a movement for about ten days when, after various means had been tried to move the bowels, a manual examination of the rectum was made under ether, and an enema of ox-gall was afterward given. The patient complained of severe abdominal pain after coming out from ether, soon went into collapse, and died twenty-four hours later.

At the autopsy a rupture through the anterior wall of the rectum was found, about four inches in length, and the ox-gall enema was mingled with the inflammatory exudation following a general peritonitis. At the junction of the descending colon with the sigmoid flexure was found a slight stricture with a large ulcer, the base of which was formed by the peritoneum. Surrounding it in the peritoneal cavity, loosely incapsulated by the agglutination of the coils of the intestines by the exudation, was a small pocket of pus. On the inner surface of the cæcum, just above the base of the vermiform appendix, was a second ulcer that had extended through the peritoneum, and which opened into a small intra-peritoneal pocket of pus, similarly incapsulated by the agglutination of the surfaces of the peritoneum. These two pockets of pus would probably both have opened soon into the abdominal cavity and produced a general peritonitis, had not the rupture of the rectum and the ox-gall enema earlier completed the clinical history of the case. The ulcers were apparently simple, and the remainder of the mucous membrane of the alimentary tract was entirely free from disease.

The last specimen was one of

IMPACTION OF A FOREIGN BODY IN THE VERMIFORM APPENDIX.

It was found accidentally at an autopsy when, so far as had been known, there had been no symptoms of any kind referable to this region. It was firmly fixed in the appendix, and the history of the other cases would have probably been repeated in this, had not an intercurrent disease cut short the life of the patient.

Dr. Biggs then concluded as follows: "During the last two years I have examined and noted, in the autopsy- and dissecting-room, the relation, condition, position, etc., of the vermiform appendix in nearly two hundred cases. I have also had a number of autopsies on other cases quite similar in all respects to those described, and, as a result of these examinations, I have come to the conclusion that, in a very large proportion of the cases of general peritonitis following ulceration and perforation of the vermiform appendix, the condition was the result of the impaction of a large foreign body in an appendix that extended freely into the peritoneal cavity, having a long mesentery and being easily movable. It is under such conditions that there are present the most favorable influences for the expulsion of any foreign matter that may make its way into the appendix. When thus situated the vermiform is moved about freely in the abdominal cavity by the peristaltic movement of the intestines, and through this constant change in position its own muscular walls are most favorably placed for expelling any matter that may make its way into its lumen. Consequently, impaction only occurs when a body of considerable size (so large that it cannot be expelled) is formed, or finds its way into the cavity. Thus the same conditions that at first made such a vermiform less liable to disease now place it under the most unfavorable conditions, so far as the patient is concerned. For the constant motion of the intestines prevents the formation of any adhesion around the appendix as the ulceration extends through its walls, and, finally, when perforation occurs, a direct communication with the abdominal cavity is at once established, and a general peritonitis is the result. I believe further that in most cases, at least where general peritonitis follows vermiform perforation, there is a direct communication with the peritoneal cavity from the first. It does not follow secondarily from rupture of an abscess into the cavity, and any operative interference, to be successful, must be early resorted to.

"As further evidence that this is the case, I would note that in cases where the vermiform is freely movable there are rarely evidences of disease or changes in its mucous membrane; while, on the other hand, when the appendix has a short mesentery, or no mesentery at all, or lies back of the cæcum coiled up and fixed in its position, or when the end is bound down at an angle with the body, there are very frequently evidences of disease in the mucous membrane. It is in such cases that there is the greatest difficulty in expelling any foreign matter that may make its way into it, and it is also in such cases that disease with ulceration, etc., is most frequent. But under these conditions the appendix is practically immovable, and before perforation occurs adhesions have formed that shut off the abdominal cavity, the process extends out into the peri-cæcal connective tissue, and perityphlitis results. Consequently this is a far more frequent result of disease of the appendix than general peritonitis. I would not, however, be understood as inferring that none of these cases result from disease of the cæcum, for some of both forms undoubtedly have their starting-point here.

"As an interesting point in the clinical history of the reported cases of general peritonitis following perforation of the appendix, I would call attention to the absence of local pain and tenderness, and the reflection of the pain to the epigastric region."

Dr. Biggs also showed a specimen of rupture of the left broad ligament, occurring in a case of criminal abortion. The greater part of the fœtus, which was at about the fourth month, lay between the layers of the broad ligament. The rupture of the uterus had begun about three-fourths of an inch above the external os.

Dr. Hamilton presented a specimen of

MULTIPLE DIVERTICULA OF THE SIGMOID FLEXURE,

removed from a man aged forty-five, who had died of chronic phthisis. The small intestine was normal. Lying on the outer surface of the sigmoid flexure, between the longitudinal muscular bands, were about a dozen spherical bodies, varying in diameter from one-sixteenth to one-half inch. On cutting into one of them it was seen to have a thin wall and to contain hard fecal matter; it communicated by a narrow channel with the interior of the intestine.

A microscopic examination of one of these diverticula showed that its wall was similar to that of the sigmoid flexure, but that the mucous membrane was compressed and flattened by the fecal contents, and the muscular layer was quite thin, and in places entirely wanting. It was evident that they were formed by a protrusion of the mucosa through the muscular coat. Diverticula in various portions of the intestines are recorded in pathological literature. Dr. Hamilton thought that the case was noteworthy for several reasons: First, the lesion was in the sigmoid flexure, where large fecal masses may accumulate. Second, a complete analogy existed between this lesion and diverticula of the bladder. Lastly, a possible result of such a lesion might be perforation, producing peritonitis and death.

Dr. Mary A. D. Jones presented two specimens of

TUMORS REMOVED FROM THE PELVIS.

The first patient gave a history of abdominal pain and distress extending over many years, and unrelieved by treatment. In fact, so much did the patient suffer that she said, the day before the operation, that if she was told that she had but one chance in twenty-five of recovery she would take that chance and have the operation. Examination showed the uterus pulled to the extreme right by shortening of the right broad ligament, and in the centre of the floor of the pelvis a soft tumor, exquisitely painful and evidently the seat of fluctuation. A diagnosis of an ovary enlarged by an abscess was made. The patient was successfully operated on by abdominal section, and both ovaries and tubes removed.

The specimen exhibited showed a portion of the left ovary to be of a hard, nodular, cheesy consistency, and the rest of it converted into a large pus-cavity, a portion of whose walls was almost of the thinness of paper; the danger of rupture, with possibly serious results, being obvious. Both tubes were in a state of chronic salpingitis. The right ovary was one-fourth of normal size and cirrhotic.

The second patient also had a fluctuating tumor in the pelvis adherent by strong adhesions. A first examination gave the impression of an enlarged and extremely retroflexed uterus, and so it had been diagnosed; but its softness and the sound passing into the uterus in the normal direction made the presence of an enlarged tube very probable. On operation the tube was found to be of the size of an orange, and completely adherent to the posterior part of the uterus and the wall of the pelvis. After separation of the adhesions, and as the mass was being lifted out of the abdominal cavity, it ruptured and quantities of dark clotted blood escaped. The patient made a good recovery.

The specimens showed the left tube to be closed at its distal end, and enlarged to three and a half inches in diameter and filled with blood; it was adherent to the left ovary. The right appendages were also bound down by adhesions, the tube adherent to the ovary and closed at its fimbriated extremity. Diagnosis, pyo-salpingitis.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 3, 1888.

Abraham Jacobi, M.D., President, in the Chair.

By vote the name of Dr. Cornelius R. Agnew was enrolled on the list of benefactors of the Academy.

At this and its last meeting the Academy came into possession of two portraits, one of Dr. John W. Francis, President of the Academy in 1848 and 1855, and the other of the late Dr. Samuel A. Purdy.

Dr. A. R. Robinson read a paper entitled

SOME STUDIES ON THE SWEAT-GLANDS.

The gland proper of the sweat-gland, which lay in the corium or subcutaneous tissue, consisted of the lower portion of the sweat-apparatus coiled upon itself, the tube terminating in a blind extremity. The duct included all that portion of the tube above the gland portion, and extended upward and opened on the surface. After further describing the structures composing the sweat-glands, and the different views of their functions, Dr. Robinson recorded some of his studies on the time and mode of development, origin, and arrangement of the structures composing the glands, their function, and certain pathological conditions observed by him.

With regard to the earliest period at which the sweat-glands commenced to develop, as in the case of the hair, bones, etc., it differed in different portions of the body; but it was probable that, in those regions where they attained their greatest development, and where present in greatest number (the palms of the hands and soles of the feet), they commenced to form first. According to Kölliker, the first sign of their development was found in the hands and feet in the fifth month of fœtal life. This was also the view of Ranvier, Klein, Biesiadecki, and others. Dr. Robinson, however, presented drawings from a section of the end of the finger of a fœtus of the eleventh week in which sweat-glands were forming, corresponding to the description of them given by Kölliker and others, *i.e.*, consisting of cones of epithelial cells, having their origin primarily from the lowest cells of the rete mucosum. There could be no mistake about the age of the fœtus. It could fairly be supposed that the sweat-glands commenced one week earlier than the abortion, or at the tenth week. He was unable to find any indication of their presence in the middle of the finger or palm. It was generally stated that the sixth month was the earliest period at which the coil part and lumen formed, while the majority of writers gave a much later period. According to the speaker's observations, at four and a half months of fœtal life the lumen already extended in some of the glands to the surface. Further, he had found that the sweat-glands opened on the ridges, where these were present, and on portions of the body deprived of them the sweat-duct was in a depression of the general surface.

Dr. Robinson thought the best division of the sweat-gland was not into the coiled part and duct part, but the secreting and the duct part, the division depending in the latter case not upon the course of the tube but upon its structure.

Regarding the formation of the lumen, different opinions prevailed. The earliest sign of preparation for lumen formation was found to be the presence of a deeply stained space between the epithelial cells about the neck portion of the retort-shaped extremity. A substance was evidently secreted which occupied the central part of the tube, and colored deeply with gold chloride. There were no signs whatever of any of the epithelial cells breaking down at this or any subsequent stage, notwithstanding such was the method of formation of the lumen, as claimed by some writers. The lumen did not always commence to form in exactly the central part of the tube, although never far from it.

Regarding the cuticula, Dr. Robinson said the excretory duct in the corium had a distinct cuticula its entire length, and this was continued very frequently within the epidermis to near the granular layer, when it ceased to exist, and the lumen was afterward lined with flattened epithelia. He had found a distinct cuticula in the rete in some cases and no trace of it in others. That the cuticula could not consist of endothelial cells, as claimed by Czerny, was evident from the fact that it developed after the lumen had attained a considerable size, and no cells were to be detected internal to the epithelial cells forming the lining, consequently their only source could be from the inner epithelium.

Regarding the epithelia, all agreed that the secreting part of the gland had a single layer, columnar or cuboidal in shape, but with regard to the duct part there was a difference of opinion, Heitzman and Biesiadecki describing only one layer of epithelial cells, while Ranvier, Klein, and others stated there were always two or more. The question was not easy to determine. Dr. Robinson, however, had found that where the tube was greatly distended only one layer existed, but that would not be positive proof of the normal condition. Transverse sections in many drawings showed two or three rows of cells, but he doubted whether the cell-section was a thin, absolutely transverse one.

Regarding the muscular layer, he said that in the well-developed glands it was not difficult to see the layer of muscle-fibre lying between the epithelium and the membrana propria, and running parallel or obliquely to the long axis of the tube. Regarding the origin of the muscle-fibres, he offered reasons for not accepting Ranvier's view that they had their origin in the epithelium.

The general view of the function of the coil, or sweat-gland, was that it secreted sweat, but this view had lately been strongly combated, especially by Unna. That they produced the fat necessary to keep the general surface oiled, instead of the sebaceous glands, seemed very probable. That being the case, the disease called seborrhœa oleosa—shining, oily skin—probably was not an affection of the sebaceous, but of the sweat-glands. But the question arose, did they produce sweat also? This question he considered in connection with the pathology of some diseases of the skin. Diversity of opinion existed with regard to the cause of the lesion in miliaria and sudamina. One thought the dewdrop-like eruption was an exudative disease, and called it malaria, while another thought it arose from retained sweat, and called it sudamina. One regarded miliaria rubra and miliaria alba as a form of eczema, the exudation coming from the sweat-glands and papillæ of the cutis; another considered it an inflammatory affection of the sweat-glands, and the contents of the lesions as sweat-products; while a third thought lichen tropicus a different disease from miliaria rubra or alba, and so on.

In a case of sudamina, or miliaria crystallina, the vesicles were always in the corneous layer, the roof and base being formed of cells from this layer, and the sweat-gland duct always opening into it at the base. The sweat-gland in the duct and coil part showed no abnormal condition. The lumen of the coil was small, and the epithelial cells normal. In both of the two cases which he described there were circulatory changes in the vessels of the corium, the lesion was situated in the corneous layer, and was in direct communication with a sweat-duct, but no changes were observed in the coil part. There were no signs of inflammation in the gland, or of a simple hyperidrosis. The vascular changes would show a vaso-motor paresis caused directly or indirectly by a neuro-paralytic dilatation, and the vesicle contents as arising probably from exudation from the blood-vessels through the rete into the sweat-duct. If the vesicles existed several days, the vascular change became more marked, and some active inflammation occurred. Miliaria rubra and alba, according to these observations, were later stages of sudamina, which latter was the result of vaso-motor paresis, and not of disease of the sweat-glands.

Lichen tropicus he regarded as a form of eczema situated around a sweat-duct, and associated with hyperidrosis. The changes showed active function, and the clinical symptoms confirmed it, for profuse sweating was always present. The exudation and the anatomical changes were similar to those in ordinary acute eczema, but occurred especially around the sweat-duct orifice instead of around a hair-follicle or non-follicular region. If his arguments as to the contents of the lesions being sweat were conclusive, then the sweat-glands furnished them, and they must be sweat-producing organs.

There was an adenitis sudoripara resembling somewhat an eczema or dysidrosis in clinical character. It consisted primarily in a hyperidrosis, with secondary cyst-formation of the duct within the corium, caused probably by stoppage of the duct lumen, either by detached epithelium or mucoid material. The affection was a special one, and as it consisted in retention of sweat, he called it, when he first described it, a form of sudamina. It showed to him decidedly that the sweat-glands were sweat-forming organs, for there was accompanying a hyperidrosis a cyst-formation of the sweat-duct, with clear neutral or acid contents, in a situation far removed from the papillary blood-vessels or juice channels of the rete. He further related a case of cystic disease of the sweat-ducts with distinct clinical characters, which he thought went to support the view that the sweat-glands secreted sweat.

DR. DANA thought with Dr. Robinson that the sweat-glands secreted sweat.

DR. CHARLES HEITZMAN thought it would be contrary to all that had been known regarding muscular fibres to suppose they passed to the epithelial layer. He did not think Unna or others had given sufficient proof of sudoriferous glands secreting fat.

THE PRESIDENT remarked that in the case of the blood-vessels, if the muscular fibres extended to the epithelia, there being no membrane between, aneurism would readily occur. The condition when present was abnormal.

Action on the proposed amendments to the constitution, to extend the area of membership, was postponed until the first Thursday in June.

A REMARKABLE CASE OF FECAL ACCUMULATION is reported by Dr. R. Worrall in the *Australasian Medical Gazette*. The patient was a girl, aged thirteen, of a cachectic appearance, who had a rapidly growing abdominal tumor. Aperients were given, and for several days a large quantity of very offensive fecal matter was discharged, but without any noticeable effect in reducing the volume of the tumor. As the child was evidently sinking, it was determined to make an exploratory laparotomy, the supposition being that the tumor was malignant. On opening the abdomen, however, the swelling was found to be an enormous accumulation of fæces in the cæcum and colon. The operation seemed to have had a stimulating effect upon the bowels, which acted almost continuously for a few days. In six days the tumor had entirely disappeared, and the child made a good recovery, her life having probably been saved by an error in diagnosis.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 17 to June 23, 1888.

WHITE, ROBERT H., Major and Surgeon. Ordered from Angel Island, Cal. to Fort Myer, Va. S. O. 142, A. G. O., June 20, 1888.

MUNN, CURTIS E., Captain and Assistant Surgeon. Ordered from Fort Klamath, Ore., to Angel Island, Cal. S. O. 142, A. G. O., June 20, 1888.

TORNEY, GEORGE H., Captain and Assistant Surgeon. Relieved from duty at Fort Monroe, Va., and ordered to Fort Randall, D. T. S. O. 142, A. G. O., June 20, 1888.

MCCREERY, GEORGE, Captain and Assistant Surgeon. Relieved from duty at Fort Meade, D. T., and ordered to Fort Monroe, Va., for duty. S. O. 142, A. G. O., June 20, 1888.

GORGAS, WILLIAM C., Captain and Assistant Surgeon, Relieved from duty at Fort Randall, D. T., and ordered to Fort Barrancas, Fla. S. O. 142, A. G. O., June 20, 1888.

MORRIS, EDWARD R., First Lieutenant and Assistan Surgeon. Leave of absence granted in S. O. 61, May 28 1888, Department of Arizona, extended one month. S. O 142, A. G. O., June 20, 1888.

POINDEXTER, J. D., First Lieutenant and Assistant Surgeon. Granted leave of absence for one month. S. O. 55, Department of Dakota, June 18, 1888.

SWIFT, EUGENE L., First Lieutenant and Assistant Surgeon. Ordered from Fort Spokane, W. T., to Fort Klamath, Ore., for temporary duty. S. O. 142, A. G. O., June 20, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending June 23, 1888.

CRANDALL, R. P., Assistant Surgeon. From Minnesota and to the Saratoga.

SHIPPEN, EDWARD, Medical Director. Placed on retired list, June 18, 1888.

SAYRE, J. S., Assistant Surgeon. To the Navy Yard, New York.

BRADLEY, MICHAEL, Medical Inspector. Ordered to examination for promotion.

KERSHNER, EDWARD, Surgeon. Ordered to Marine Rendezvous, New York.

WHITE, C. H., Surgeon. Detached from Museum of Hygiene and wait orders.

TRYON, J. RUFUS, Surgeon. From Marine Rendezvous, New York, and special duty, New York.

MCCARTY, RUFUS, Passed Assistant Surgeon. From Naval Hospital, Chelsea, Mass., and to the Yantic.

HENNEBERGER, L. G., Passed Assistant Surgeon. From special duty, New York, and to the Minnesota.

KITE, I. W., Assistant Surgeon. From Yantic and to the Richmond.

WOOLVERTON, WHITE, WOODS, and DUBOIS, Surgeons. Ordered for examination, preliminary to promotion to the grade of Medical Inspector.

CREMATION IN BUENOS AYRES.—During the past year 993 bodies were cremated in that city, of which number 742 were of persons dead of cholera, small-pox, and other contagious diseases.

INDEX.

A

Abbe, Dr. Robert, Dupuytren's finger contraction, 236; gangrene of the ischiorectal fossa, 294.
Abdomen, contusions of, with intestinal lesions, 421; gunshot wound of, with discharge of bullet per anum, 608.
Abdominal injury, two unusual and fatal cases of, 439.
Abdominal surgery, a year's work in, 345; notes on, 174.
Abducting prisms, levelled, 316.
Abscess, perityphlitic, 12.
Abscesses, mammary, evacuation of, through their natural outlets, 607.
Academy of Medicine in Ireland, transactions of, 643.
Academy of Medicine of New York. See New York Academy of Medicine.
Accommodation of the eye, reflex paralysis of, due to dental irritation, 211.
Accouchement in a railway closet, 97.
Acetonuria in children, 715.
Acid, benzoic, solubility of, 596; carbolic, camphorated, 678; glycocholic and fellic, notes on, 576; gymnemic, 120; uric, the pathology of, 609.
Acne, resorcin in the treatment of, 21; treatment of, 701.
Aconitine, dangers of, 612; varieties of, 612.
Acromegoly, 558.
Actinomycosis in a woman, 125.
Addison's disease, 611.
Address, anniversary, before the Medical Society of the State of New York, 141.
Adenitis, axillary, the significance of, 15.
Adenoid tissue, hypertrophy of, in epiglottidean fossa, 132.
Adulterations, a bureau of, 247.
Agnew, Dr. Cornelius Rea, obituary of, 446; resolutions on the death of, 474, 540, 568, 649; the lesson of his life, 472.
Alabama State Medical Association, 540.
Albuminates in medicine, 519.
Albuminuria, and injections of albumen, 552; chronic, some points in the treatment of, 320, 338; clinical significance of, 500; clinical study of, 675; hematogenous, 70; intermittent or so-called cyclic, 304; of pregnancy, 155; of pregnancy, induction of premature labor in amaurosis and amblyopia, in connection with, 93, 106.
Alcohol, and heart disease, 417; and race, 546; as a food, 73; consumption of, on mortality and health, 28; hereditary degenerative influence of, 707; in fevers, 162; in therapeutics, 647; question, the Gothenburg method of dealing with, 336; to remove water from, 428.
Alcoholic ataxia, 299.
Alcoholic automatism, 695.
Alcoholism, acute, subcutaneous injections of ammonia in, 82.
Alexander's operation for procidentia uteri, 240, 300.
Ambrook, Dr. Charles, the results of jury trials in lunacy in the State of Colorado, 256.
American Association for the Cure of Inebriates, 706.
American Association of Medical Editors, 582.
American Medical Association, thirty-ninth annual meeting, 521, 524, 561, 589; Section on Dermatology and Syphilography, 589; Section on Diseases of Children, 617; Section on Obstetrics and Gynecology, 563, 645; Section on Practice of Medicine, 531, 591; Section on State Medicine, 590; Section on Surgery, 561.
American physicians, European opinion of, 52
American Surgical Association, transactions of, 420.
Americans, the size of, 19.
Amputation, osteoplastic, of the thigh, 665.
Anal canal, observations on the normal sacculi and on the preternatural pouches of, 569.
Anatomy, the study of, 522.
Anæmia, cause of, 139; fæcal, 44, 56; gold for, 474; pernicious, 407, 423; progressive pernicious, 350
Anæsthesia, general, from cocaine, 101.
Anæsthetic, a new local, erythrophlœine, 159, 363, 634; bichloride of methylene as an, 698; for obstetrical practice, 588.
Anæsthetics, valuable lesson for those who use, 63.
Anderson, Dr. B. P., Colorado as a health-resort, 314.
Andrews, Dr. E. Wyllis, notice of book by, 644.
Aneurism, abdominal, Scheele's test for, 134; aortic, a new symptom of, 258; aortic, some observations on, 365; of the interauricular septum, 370; of the internal pudic artery, 478; of the thoracic aorta, 635; thoracic, treatment of, by Moore's method, 41; traumatic, of the leg, 369.
Angiocholitis, non-calculous, 584.
Angioma of the epiglottis, 609.
Anodyne, antifebrin as an, 45.
Ano-vesical centre, seat of the, 288.
Anthrax, a case of, 473.
Antifebrin, as an anodyne, 45; as a hypnotic, 199.
Antipyrin, action of, on urinary secretion, 76; hypnotic action of, 140, 260; in acute and painful eye affections, 200; in nocturnal emissions, 708; in neuralgic headache, 39; in obstetric practice, 39; some of the uses of, 68; some toxic effects of, 14.
Antipyretics, the modern, 696.
Antisepsis, acid bichloride solutions in, 298; simplified, in obstetrics, 203.
Antiseptic, internal, naphthol as an, 41; ligature reel, 111; preparations, 652; treatment, v. Bergmann's method of, 611; values, comparative, of chlorides, nitrates and sulphates, 552.
Aorta, thoracic, aneurism of, 78, 635.
Aortic valve, perforations in, without regurgitation, 78.
Apostoli, Dr. Georges, notice of book by, 643.
Apostoli's method vs. hysterectomy, 551.
Apothecaries' weight, 414.
Appendix, vermiform, diseases of, 720.
Aproxia from nasal disease, 74.
Army and Navy news, 28, 54, 82, 139, 172, 202, 232, 287, 316, 344, 372, 428, 455, 512, 539, 567, 623, 649, 678, 705.
Army, report of the surgeon-general of the, 18.
Arsenic, causing cancer, 19; efficacy of large doses of, in chorea, 415.
Arsenical paralysis, a case of, 599.
Arterial tension, relation of convulsions to, 202.
Arteritis, obliterating, 555.
Arthritis, rheumatoid, the nervous origin of, 193; iodine in, 584.
Articular rheumatism, chronic, therapeutics of, 202.
Ascites, subcutaneous drainage in, 328.
Aseptic cases for surgical instruments, 124.
Asiatics, effects of alcohol upon, 546.
Asthma, excursions upon the water for, 637.
Astragalus mollersimus, 197.
Ataxia, alcoholic, 299.
Atkins, Dr. E. C., shall surgical inventions be patented? 372.
Atkins, Dr. Francis H., the health of Las Vegas, N. M., 469.
Atomizer, an improved, 171.
Automatism, alcoholic, 695.
Ayers, Dr. Edward A., version before labor in malpositions of the fœtus, 581.

B

Baader, Dr., death of, 567.
Bacteriological water-tests, 304.
Bacteriology and practical medicine, 532.
Baldness, congenital, 441.
Ball, Dr. Charles B., notice of book by, 644.
Ball, Dr. R. R., antipyrin in neuralgic headache, 39.
Bandl, Dr. L., book notice, 104.
Barber, Dr. C. F., some toxic effects of antipyrin, 14.
Barker, Mr. Arthur E. J., notice of book by, 4 0.
Barker, Dr. Fordyce, remarks on the albuminuria of pregnancy, 155.
Bartholow, Dr. Roberts, book notice, 104.
Baruch, Dr. Simon, concerning specifics in diphtheria, 231.
Basedow's disease, 452, 508.
Bastian, Dr. H. Charlton, notice of book of, 419.
Bath, continuous, in skin lesions, 466; nutritive, the value of, 633.
Baths, hot, for insomnia, 708.
Belfield, Dr. William T., note on the surgery of the enlarged prostate, 272.
Belladonna poisoning, a case of, 243.
Benzol in whooping-cough, 15.
v. Bergmann's method of antiseptic treatment, 611.
Bernays, Dr. A. C., the German Surgical Congress, 538.
Bertani, Agostino, a statue to, 640.
Bertherand, Dr. A., notice of death of, 388.
Bessels, Dr. Emil, death of, 392.
Bichloride solutions, acid, in antisepsis, 298.
Bile, the rôle of, in the digestion of fat, 612.
Bile-duct, fatal stricture of, without gall-stones, 15.
Bilharzial epicystitis, 552.
Biliary colic, olive-oil in, 217.
Birth, six living children at a, 672.
Births, multiple, 210.
Bladder, foreign body in, 447; intraperitoneal rupture of, 441; irritability of, hyoscyamus in, 140; irritable, formula for, 273; neuralgia of, 665; operative treatment of stone and tumors of, 113; papillomatous tumor of, demonstrated by Leiter's electro-cystoscope, 493, 540, 640; rapid emptying of, alarming effects following, 651; rupture of, through fracture of the ramus of the pubes, 49; tumor of, diagnosis of, by the cystoscope, 596; tumors of, irritation as a cause of, 552; urinary, intraperitoneal rupture of, 632.
Blindness following a lightning-stroke, 707.
Blood-clot, organization of, 51.

Blood-corpuscles, work of, in the animal economy, 512.
Blood, human and animal, to distinguish between, 706; in diabetes, 610; in tuberculosis, 20.
Blood-stains, new method for identifying, 168.
Board of Health, New York State, governor's recommendation to abolish, 19.
Bodenhamer, Dr. William, observations on the normal sacculi of the anal canal, both in health and in disease, and also on the preternatural pouches of the same region, as described by Dr. Physick, 569.
Bodley, Dr. Rachel L., death of, 697.
Boerner, Dr. E., book notice, 103.
Boils and carbuncles, treatment of, 219, 313.
Borck, Dr. Edward, diseases of, and operations on, the testicles, 547.
Boursier, Dr. André, notice of book by, 643.
Boy pianist, the overworked, 221.
Boyd, Dr. J. M., some clinical observations on diphtheria, and veratrum viride as the basis of treatment, 627.
Bovee, Dr. J. W., furrows in the finger-nails, 686.
Bowels, fatal obstruction of, 199; obstruction of, due to adherent diverticulum, 62.
Bowman, Dr. B., cocaine in removing a scalp tumor, 257.
Brain cortex stained by Golgi's method, 283.
Brain, duality of, 16.
Breath, the human, a poison, 316.
Bressler, Dr. Frank C., hysterical fever, 466; paroxysmal trachycardia, 11.
Bright's disease, acute, 151; acute, in children, 163; acute, pathological changes in the eye in, 163; chronic, a formula for, 407; juice of the century-plant in, 705; pathogeny of, 552; pilocarpin in, 106; relation of, to heart diseases, 485; Semmola's formula for, 279; some points in the treatment of, 320, 338; without albuminuria, 253.
Brochin, Dr. Robert Hippolite, notice of death of, 446.
Bromide of iron, therapeutic properties of, 637.
Bronchitis, the dyspnœa of, 276.
Brown, Dr. Elizabeth Stow, on the application of Alexander's operation to procidentia uteri, with report of two cases, 240.
Brown, Dr. John Young, intra-peritoneal rupture of the urinary bladder—laparotomy—death, 632.
Browne, Mr. Lennox, hypertrophy of glandular tissue at the base of the tongue, 171.
Browne, Mr. Lennox, notice of book by, 419.
Buckmaster, Dr. A. H., the local treatment of pulmonary disease, 53.
Bull, Dr. Wm. T., report of cases of intestinal obstruction treated by laparotomy, 205.
Bullet-probe, the telephonic, 117.
Burchard, Dr. T. H., the treatment of stricture of the urethra by electrolysis, 655.
Burnett, Dr. Swan M., on trachoma among the negroes in the United States, 342.
Burns, quebracho in, 56.
Burrows, Dr., plaster-of-Paris in the treatment of club-foot, 288.
Buttermilk in the nutrition of invalids, 612.
Byford, Dr. W. H., notice of book by, 672.

C

Cæsarean section and craniotomy, 506.
Caillé, Dr. Augustus, a method of prophylaxis in diphtheria, 183.
Calcium sulphide in pulmonary phthisis, 12.
Calculi, uric acid, the problem of dissolving, 303.
Calculus, renal, impacted, 576, 593; vesical, operative treatment of, 113.
Calomel, in the prevention of pock-marks, 67.
Calomel stools, so called, cause of the color of, 221.
Cammann, Dr. D. M., terpine in diseases of the lungs, 711.
Camphorated carbolic acid, 678.
Cancer-bacillus, and sarcoma-bacillus, 221; the so-called, 364.
Cancer, from the use of arsenic, 19; inoculation of, 536; medullary, diagnosis of, 125; of the lip, non-recurrence of, after excision, 311; of the stomach, cundurango in, 650; of the uterus, pure terebene in, 201; primary, of the Fallopian tube, 595; prognosis of, 534; the nature of, 698; treatment of, by inoculation of erysipelas, 474; treatment of, by the suction of toads, 483; unusual case of, 327; Virchow on, 195.
Canfield, Dr. W. B., notice of translation by, 102.
Cannabis indica in tropical and dyspeptic diarrhœa, 357.
Carbuncles, and boils, treatment of, 313; local applications of carbolic acid in, 520, 634; new treatment for, 219.
Carcinoma, and syphilis, 193; colloid, of the peritoneum, 477; early stages of, 605; recurrence of, after operation, 448.
Cardiac, disease, influence of, on the mind, 679; excitant, pyridin as a, 666; movements, some new studies of the, 585; neurotics, combination of, 541; tonic, sparteine as a, 666.
Cardiocentesis, 99.
Caries, dental, in clarionet-players, 47.
Carleton Dr. C. G., the treatment of boils and carbuncles, 313.
Carlsbad notes, 83.
Carman, Dr. F. W., post-partum hemorrhage after drinking mulled ale, 665.
Carpenter, Dr. A. B., a new method of supplying the continuous or galvanic current in the treatment of fibroid tumors of the uterus, 356.
Carpenter, Dr. Wesley M., obituary notice of, 48; resolutions on the death of, 102, 131.
Cartwright lectures on the general pathology of fever, 373, 401, 457.
Castle, Dr. Frederick A., the use of proprietary medicines by the laity and the profession, 515.
Castration and the development of the genital tract, 679.
Cataract, extractions, 161; results of operations for, 596.
Catheterization, exploratory, of the male ureter, 715.
Cautery, actual, methylene chloride with, 41.
Cautery-snare for removal of posterior hypertrophies of the turbinated bones, 315.
Cellulitis, pelvic, unusual cases of, and their treatment, 653, 673.
Cellulo-microbian warfare, 172.
Centre, ano-vesical, seat of the, 288.
Century-plant, juice of, in Bright's disease, 705.
Cerebral, localization and Brown-Séquard, 414; symptoms in pneumonia of children, 385, 398; tumor, 452; tumors, diagnosis and surgery of, 450.
Cerium oxalate, as a remedy for cough, 602; in sea-sickness, 704; in sea-sickness and other disorders, 608.
Cervix and perineum, operations on, a suture-fastener for use in, 673.
Chancre, double, à distance, 590; gingival, 607.
Chapman, Dr. E. A., a case of belladonna poisoning, 243.
Chappell, Dr. W. Franklin, suppurative peritonitis and pleuritis following parturition—drainage and recovery, 692; treatment of carbuncle with carbolic acid, 634.
Charities, N. Y. State Board of, governor's recommendation to abolish, 19.
Cheesman, Dr. Hobart, oxalate of cerium as a remedy for cough, 602.
Cheesman, Dr. Wm. S., the oral whiff, 235, 427.
Chest, penetrating gunshot wounds of, 301.
Chilblains, to relieve, 411.
Childbirth, effect in, of Wormian bones in fontanelles, 412, 424.
Children, acute Bright's disease in, 163; chronic atrophic spinal paralysis in, 295; feeble-minded and backward, auxiliary public schools for, 586; menstruation in, 640; pancreatic carcinoma in, 584; primary mycotic nephritis in, 301; pneumonia of, cerebral symptoms in, 385, 398; salt in milk for, 707; six living, at a birth, 672; treatment of predisposition to phthisis in, 620.
Chisolm, Dr. Julian J., a very valuable lesson for those who use anæsthetics, 63.
Chloranæmia symptomatic of endo-cervicitis, 290.
Chlorides, nitrates, and sulphates, comparative antiseptic values of, 552.
Chloroform, discoverer of, 223; resuscitation in threatened death from, 663.
Chlorosis, and heart disease, 88; sulphur in, 156.
Cholecystotomy, 244.
Cholera and milk, 176.
Cholera infantum and the weather, 317, 337.
Cholera, in Chili, 712; Pettenkofer and his most recent views in, 72.
Chorea, 618; and rheumatism, relationship of, 21; treatment of, by cerebral rest, 3, 21.
Chrobak, Dr. R., book notice, 103.
Chromium, physiological action of, 82.
Church, Dr. Charles A., unusual effects from salol, 244.
Cigar-makers' cramp, 22.
Cirrhosis of the liver, some interesting clinical phenomena observed in a case of, 579, 593.
Civilization and medicine, 695.
Clark, Alonzo, M.D., memorial of, 122.
Clarke, Dr. John M., alcoholic ataxia, 299.
Classified and descriptive directory to the charitable and beneficent institutions of the city of New York, 644.
Clavicle, fracture at the inner end of each, 478.
Cleveland, Dr. E. S., the oral whiff, 343.
Climate, selection of, for cases of pulmonary phthisis, 668.
Climatic treatment of phthisis, 301.
Club-foot, immediate application of the plaster-of-Paris splint in the treatment of, 34; plaster-of-Paris in the treatment of, 288; relapsing, 50; treatment of, by open incision, 49.
Cocaine, general anæsthesia from, 101; reflex inhibitory action of, 137; removal of a scalp tumor under, 257; saccharinate of, 46, 393.
Coe, Dr. Henry C., the use of the curette for the relief of hemorrhage due to uterine fibroids, 90.
Colchicum for gout, 15.
Colic, hepatic, treatment of, by olive oil, 46.
Colon, dilatation of, laparotomy for, 636.
Color-blindness a brain affection, 69.
Colorado as a health-resort, 314.
Coma, hysterical, a case of, 273.
Commitment of the insane, 157.
Comstock, Dr. T. Griswold, Lawson Tait's method in plastic operations, 170.
Congenital syphilis, a contribution to the etiology of, 330.
Congress of French surgeons, 391.
Conkey, Dr. Caroline R., a new form of pessary for the relief of prolapsus uteri, 54.
Connecticut State Medical Society, 646.
Conover, Dr. Jacob D., death of, 615.
Constipation, among the French, 111; tincture of nux vomica in, 131.
Consumption, Christian scientists' theory of, 473; pulmonary, sulphurous acid in the treatment of, 358.
Consumptives, pauper and indigent, the treatment of, 416.
Contagious diseases, weekly statement, 28, 55, 82, 111, 139, 172, 202, 232, 257, 287, 316, 344, 372, 400, 428, 456, 484, 512, 540, 568, 596, 624, 649, 678, 706.
Convulsions, relation of, to arterial tension, 202.
Conway, Dr. John R., death of, 616.

Cooper, Dr. Theodore H., notice of death of, 19.
Cord, spinal, combined sclerosis of, 107.
Cornea, opacities of, removal of, by galvanism, 704; transplantation of the, 560, 698.
Corneal ulcers, eserine in, 690.
Corning, Dr. J. Leonard, a further contribution on local medication of the spinal cord, with cases, 291; the treatment of chorea by cerebral rest, 3.
Cough, oxalate of cerium as a remedy for, 602.
Courts, medical cases in the, 606.
Cracked nipples, treatment of, 568.
Craig, Dr. James, death of, 222.
Cramp, cigar-makers', 22; waiters', 22.
Craniometry, some of the principles of, 681.
Cranium, treatment of gunshot wounds of the, 165.
Creasote in phthisis, 441.
Creolin, 584; in cystitis, 509.
Cretinism, sporadic, 609.
Crime, periodicity of, 228.
Crosby, Dr. George A., death of, 132.
Crothers, Dr. T. D., mental responsibility in inebriety, 189.
Croup, membranous, treatment of, with bicarbonate of soda, 243.
Crown prince of Germany, and his physicians, 276; why one arm is shorter than the other, 504, 539.
Cundurango in cancer of the stomach, 650.
Curious affection, 100.
Curtis, Dr. B. Farquhar, early stages of carcinoma, 605.
Cystic tumors, abdominal, early removal of, 645.
Cystitis, creolin in. 509.
Cystoscope, the diagnosis of vesical tumor by the, 493. 540, 596, 640.

D

Dabney, Dr. S. G., the use of erythrophlœine as a local anæsthetic, 634.
Da Costa, Dr. J. M., on the relation of diseases of the kidney, especially the Bright's diseases, to the diseases of the heart, 485.
Dana, Dr. C. L, an atypical case of Thomsen's disease (myotonia congenita), 433.
Darwin as a medical student, 134.
Darwin's father, anecdote of, 708.
Davidson, Dr. A. R., death of, 642.
Dawley, Dr. L. B., a case of typhoid fever with some peculiar features, 200.
Dawson, Dr. Benjamin F., death of, 390.
Dead, a new method of disposing of the, 472.
Deaf, teaching the, in the public schools, 704.
Deaf-mutism, the cure of, 194.
Deane, Dr. W. H., diabetes mellitus in an infant, 97.
Death, by electricity, 158; from fright, 191; unreliable sign of, 192.
Death-penalty, by electricity, 73.
Delafield, Dr. Francis, acute Bright's disease, 151; memorial of Alonzo Clark, M.D., 122.
Delirium tremens, methylal in, 551.
Deming, Dr. W. C., intubation of the larynx, asphyxia from obstructed tube, 198.
Depew, Mr., on the doctor, 695.
Derby, Dr. Richard H., insufficiencies of the ocular muscles, 232, 437.
Dermatological negatives, 352.
Dermepenthesis, 638.
Diabetes, blood in, 610; curability of, 70; jambul in, 174; mellitus in an infant, 97; pancreatic, 641; to allay thirst in, 671.
Diarrhœa, summer, sour milk in, 553; tropical and dyspeptic, cannabis indica in, 357.
Diarrhœa, infantile, classification and treatment of, 246.
Dibble, Dr. LeRoy, winter itch, by a victim of nine years' standing, 427.
Dietetics, report of committee on, of the American Medical Association, 527.
Diets, animal and vegetable, compared, 54.
Digestion of fats, 694.
Digitalis, in the treatment of pneumonia, 275; limit of employment of, 568.
Diphtheria, antiseptic treatment of the throat in, 307; and herpetic sore throat, 225; comparative statistics of the treatment of, 175; in poultry and its relation to the disease in man, 389; laryngeal, cubeb in, 260; prophylaxis of, 105, 183; renewed attacks of, 105; sodium hyposulphite in, 140; treatment of, 201; turpentine in, 127; veratrum viride in the treatment of, 627.
Disease germs and environment, 71.
Diseases, infectious and infective, pathology of, 583.
Dislocations of the shoulder, a rapid and simple method of reducing, 357.
Dispensary, a law, 303.
Distance, action of medicines at a, 44.
Diverticula of the sigmoid flexure, 721.
Diverticulum, intestinal obstruction caused by, 242.
Doctor, Mr. Depew on the, 695; the village, 652.
Doctors as story tellers, 502.
Dosimetric prescription, 388.
Douche, intra-uterine, indications for, in the puerperal state, 282, 296.
Drake, Dr. F. R. S., notice of death of, 307.
Dress, children's winter, 83.
Dressings, sterilized, 666.
Drinking, moderate, influence of, on health, 98, 360.
Dropsy, intermittent articular, 657.
Drug eruptions, 400.
Drugs, the action of, at a distance, 471.
Drum membrane, a novel artificial, 714.
Drzewiecki, Dr. Joseph, the use of calomel in the prevention of pitting in small-pox, 67.
Ductus arteriosus, patent, 369.
Dunster, Dr. Edward S., notice of death of, 559; resolutions on the death of, 641.
Dupuytren's finger contraction, 236.
Dysentery, symposium on the treatment of, 70.
Dysmenorrhœa, relief of, 494.
Dyspepsia, septic, treatment of, 387.
Dyspepsias, classification of, 585.
Dyspnœa, inhalations of carbonic acid in, 678; of bronchitis, 276.

E

Ear, affections, some points in the management of the Eustachian tube in, 186; dangerous inflammation of, 416; diseases, the diagnosis of, without instruments, 354; fungus in the, 83.
Ecchondroses of the septum narium and their removal, 180.
Eczema, etiology and treatment of, 589.
Edes, Dr. Robert T., book notice, 104.
Editors, Medical, American Association of, 582.
Education, medical, progress in, in the United States, 129.
Edwards, Dr. F. W., a peculiar case, 243; antipyrin in measles, 258; eighty-one days without a natural movement from the bowels—stricture of the rectum, 440.
Edwards, Dr. R. T., a case of superfecundation, 201.
Effervescent form for the administration of certain remedies, 676.
Elbow, operative treatment of old injuries of, 478; primary excision of, 311.
Electricity, and embryonal development, 42; death by, 158; death-penalty by, 73.
Electro-cystoscope of Leiter, papilloma of the bladder demonstrated by the, 493, 540, 640.
Elliott, Dr. George R., some interesting clinical phenomena observed in a case of cirrhosis of the liver, 579.
Embryonal development and electricity, 42.
Emissions, nocturnal, antipyrin in, 708.
Empyema, surgical treatment of, 618; treatment of, 447.
Endocarditis, chronic, specimen of, 77; ulcerative, 369; verrucous, 135.
Endocervicitis, chloranæmia pathognomonic of, 290.
Endometritis treated by drainage and by packing with iodoform gauze, 533.
Enteritis, chronic membranous, with periodical exacerbations, 199, 664.
Enterostomy or laparotomy? 233.
Epicystitis, bilharzial, 552.
Epiglottidean fossa, hypertrophy of adenoid tissue in the, 133.
Epiglottis, angioma of the, 609.
Epithelioma, laryngis, 368; of the œsophagus, 719; treated by chlorate of potash, 456; treatment of, by Marsden's paste, 445.
Epilepsy, mortality of, 467; ocular symptoms of, 76; treatment of, with the actual cautery, 707; trephining for, 108.
Epps, Mr. Washington, a small scarf-pin swallowed by an infant, 665.
Ergot valueless in uterine subinvolution, 111, 650.
Erlenmeyer, Dr. Albrecht, notice of book by, 672.
Erysipelas, cancer treated by inoculation of, 474.
Erythrophlœine, 159, 363, 417, 634.
Eserine and corneal ulcers, 690.
Estlander's operation for empyema, 447.
Ethical reflections, 329.
Eustachian tube, some points in the management of, in certain ear affections, 186.
Euthanasia, 46.
Evolution, the present position of, 305.
Ewell, Dr. Marshall D., notice of book by, 643.
Excision, primary, of elbow, 311.
Exercise, long life without, 478.
Expectorant, gravity as an, 39, 388.
Extra-peritoneal incisions in the linea alba for the purposes of exploration, 158.
Extra-uterine pregnancy, delivery through the vagina, 68.
Eye, affections of, acute and painful, antipyrin in, 200; insufficiency of muscles of, 81, 138, 256, 286, 343; new bandage for, 288; pathological changes in, in acute Bright's disease, 163; refraction of, new method of testing, 454.
Eyes of school-children, 288.

F

Fæcal accumulation, a remarkable case of, 723.
Fæcal anæmia, 44, 56.
Fallopian tube, primary cancer of, 595.
Family physician of the future, 52.
Fat, digestion of, the rôle of bile in, 612.
Fat-necrosis in the pancreas, 477.
Fats, digestion of, 694.
Feeble-minded and backward children, auxiliary public schools for, 586.
Fees, hints bearing on, 456; medical, low, 554.
Fever, etiology of, 457; general pathology of, 373, 401, 457; hysterical, 466; new form of, in Texas, 101; puerperal, from various causes, 6; typhoid, and pregnancy, 580; typhoid, etiology of, 203; typhoid, with some peculiar features, 200.
Fevers, treatment of, in children, 618.
Fibroid tumors of the uterus, a new method of supplying the continuous or galvanic current in the treatment of, 356.
Fibula, fracture of, from adduction of the foot, 51.
Finger, Dupuytren's contraction of, 236.
Finger-nails, furrows on the, 417, 686; mycology of the, 275.
Finlay, Dr. Charles, the microbe of yellow fever, 622.
Fisher, Dr. F. J. T., the treatment of diphtheria, 201.
Flat-foot, treatment of, 289, 310.
Fliesburg, Dr. Oscar A., skin eruptions following the administration of drugs, 400.
Flint, Dr. Austin, notice of book by, 672.
Fœtus, malpositions of, version before labor in, 581.
Folie gynécologique, 45.

Food, adulteration, a bureau of, 247; and drinks, temperature of our, 130; how much a man consumes, 568.
Foramen ovale, incomplete closure of, 369, 370.
Foreign bodies, in the alimentary canal, 273; in the intestines, 13; in the pharynx, 387; two cases of, 201.
Foster, Dr. J. W., some experiences with winter itch, 257.
Fothergill, Dr. J. Milner, the neurotic, with indigestion and lithiasis, 1.
Foville, Achille, notice of death of, 75.
Fox, Dr. G. H., on divers species of itch, 494.
Fracture, depressed, of the frontal bone, 634; exceptional, of the lower end of the humerus, 311; ununited, resection of femur for, 38.
Fractures through the head of the radius, 213.
France, statistics of the medical profession in, 559.
French, Dr. Willis W., notice of death of, 308.
French Surgical Congress, 421, 447.
Fridenberg, Dr. A. H., a rare form of vasomotor disease, 657.
Fright, death from, 191.
Frost-bites, quebracho in, 56.
Fuchs, Dr. A. F., toxic effects from small doses of potassium chlorate, 97.
Furuncles, abortive treatment of, 260; treatment of, 397.

G

Gall-stone, intestinal obstruction from, 394.
Gall-stones, or soap? 413; treatment of, by olive oil, 46, 215, 217; various effects of, 68.
Galvanic current, cumulative action of, 365, 435.
Galvanic method of treating vegetable parasitic diseases of the scalp, 590.
Gangrene, in diabetes, operation for, 168; of the ischio-rectal fossa, 294, 312.
Gardinier, Dr. Herman C., aneurism of the thoracic aorta, 635.
Gardner, Dr. W. H., oxalate of cerium in sea-sickness and other disorders, 608.
Garrigou-Desarènes, Dr., notice of book by, 672.
Gasteroliths, 217.
Gastrectasia, some clinical points on, 120.
Gastric diseases, diagnosis of, 592.
Gastric juice, acidity of the, and the diagnostic value of its variations, 218; chronic hypersecretion of, and its treatment, 71; hydrochloric acid in, 41; in cancer of the stomach, 46.
Gastric secretions, chemical examination of, 598.
Gaultheria, poisoning from, 140.
Genu varum or valgum, 328.
German Congress for Internal Medicine, 651.
German Surgical Congress, 534, 538.
German, Dr. Wm. H., some of the uses of antipyrin, 68.
Germany, Crown Prince of, cause of the shortened arm of, 504, 539.
Germs, disease, and environment, 71.
Gerster, Dr. Arpad G., notice of book by, 644.
Gillette, Dr. Arthur A., perityphlitic abscess, 12.
Gillette, Dr. H F., the treatment of septic dyspepsia, 387.
Ginger-drinking, 160.
Girdner, Dr. John Harvey, the telephonic bullet-probe, 117.
Gland, prostate, hypertrophy of, 57.
Glassblowers' syphilis, 172.
Gleitzmann, Dr. J. W., a new cautery-snare for removal of posterior hypertrophies of the turbinated bones, 315.
Globulins, vegetable, 612.
Glomerular nephritis, 173.
Glossodynia, 82.
Goldenberg, Dr. Herman, experimental observations on litholysis, 513.
Goldsmith, Middleton, lecture for 1888, 485.
Goldsmith, Dr. Middleton, biographical sketch of, 496.
Goldsmith, Dr. William B., notice of death of, 444.
Golgi's method, brain cortex stained by, 283.
Gonorrhœa, and sterility, 20, 140; thallin in, 244, 364; therapy of, 586.
Gonorrhœal peritonitis, 293.
Goodell, William, book notice, 103.
Gottheil, Dr. W. S., on the occurrence of constitutional syphilis without other than initial symptoms, 629.
Gouley, Dr. John W. S., notice of book by, 420.
Gout, colchicum in, 15; etiology of, 595.
Gouty diathesis, dietetic treatment of, 165.
Gouty urethritis, 288.
Graddy, Dr. L. B., idiopathic multiple cranial neuritis, 413.
Grafts, mucous, 535.
Grandin, Dr. Egbert H., book notice, 103.
Gravity as an expectorant, 388.
Gray's Anatomy, new edition of, 419.
Griffin, Dr. E. Harrison, a case of complete adhesion of the soft palate to the pharynx, with an operation for its cure, 37.
Grindelia robusta in pertussis, 74.
Gunshot wound, of abdomen, with discharge of bullet per anum, 608.
Gunshot wounds, of the cranium, treatment of, 165; of the visceral cavities, treatment of, 421; penetrating, of the chest, 301.
Gymnemic acid, 120.

H

Habart, Dr. Jean, book notice, 104.
Hackl, Dr. J. E., notice of death of, 560.
Hæmaturia, following severe blow on the loin, 171; large doses of alum in, 593.
Hæmatoma, spontaneous, of the orbit, 422.
Hair, and the mind, 294; yellow, 430.
Hall, Dr. C. H. H., removal of opacities of the cornea by means of galvanism, 704.
Hall, Dr. F. De Haviland, book notice, 104.
Hallux rigidus, 111.
Harlan, Dr. Herbert, eserine and corneal ulcers, 690.
Harrison, Reginald, on some points in the surgery of the urinary organs, 29, 57, 113.
Hartwig, Dr. Marcell, some random clinical notes, 328.
Headaches, treatment of, by nitro-glycerine, 204.
Head-drop, 100.
Health of New York and London, 443.
Health, influence of moderate drinking on, 98.
Health-resort, Colorado as a, 314.
Hearing, loss of, increased pensions for, 110.
Heart disease, and chlorosis, 88; and marriage, 334; for half a century, 230; relation of kidney diseases to, 485; sparteine in, 56.
Heart, failure of the, in valvular disease, and its treatment, 305; food, oxygen as a, 693; hypertrophy and dilatation of, without fatty degeneration, 78; lesions, a series of, 323; movements, some new studies of the, 585; reptilian, 353; rupture of, 78, 369; stimulant, strychnine as a, 202; tonics, the action of, 363.
Hebra's water-bed, 466.
Heed, Dr. Harmon, death of, 671.
Hemianopsia, a case of, 22, 599; bitemporal, 23.
Hemiopic pupillary reaction, 22.
Hemorrhage, ante-partum, 13; due to uterine fibroids, the use of the curette for the relief of, 90; intestinal, death from, 67; post-partum, after drinking mulled ale, 665; tar water in, 680.
Hepatic incompetence in children, 618.
Hepatic stimulants, 160.
Hereditary degenerative influence of alcohol, 707.
Hereditary syphilis, late, 395.
Hernia, inguinal, treatment of the sac in, 505; mechanical treatment of, 162; radical cure of, 69, 139, 422, 700.
Heroism, medical, 559.
Herpetic sore throat and diphtheria, 225.
Herrick, Dr. O. E., some of the simple methods of performing hystero-trachelorrhaphy, 573.
Heydenreich, Dr. Albert, notice of book by, 642.
Hiccough, remedy for, 280.
High license and the profession, 501.
Hill, Dr. Horace G., poisoning by chlorate of potash, 635.
Hip-disease, pathological specimen of, 77, 78, 109.
Hippocrates, oath of, 308.
Hoffman, Dr. Adams C., resolutions on the death of, 140.
Hogeboom, Dr. Charles L., the treatment of membranous croup with bicarbonate of soda, 243.
Holmboe, Dr. A., aseptic cases for surgical instruments, 124.
Holt, Dr. L. Emmett, cerebral symptoms in the pneumonia of children, 385; umbilical tumor in an infant formed by prolapse of the intestinal mucous membrane of Meckel's diverticulum, 431.
Homans, Dr. John, ovariotomy in a patient eighty-two years and four months of age—recovery, 496.
Hopkins, Dr. George E., the value of the nutritive bath and of inunction, 633.
Hospital physicians and governing boards, 248.
Hospital, the, as a nuisance, 696.
House poison, 83.
Hudson, Dr. E. Darwin, notice of book by, 644.
Humerus, exceptional fracture of lower extremity of, 311.
Hunter, Dr. James B., unusual cases of pelvic cellulitis and their treatment, 653.
Hutchinson, Mr. Jonathan, book notice, 103.
Hydatid, cysts of the liver, treatment of, 448; disease of the liver, incision of the cyst in, 551; tumors, dogs in relation to, 16; tumors, question of operative interference in, 204; urticaria, pathogeny of, 284.
Hydatids in bone, 176.
Hydrochloric acid, the significance of, in the diagnosis of gastric disorders, 471, 716.
Hydrogen, rectal insufflation with, as a diagnostic measure in abdominal injuries, 562.
Hydronaphthol in the treatment of lupus, 204.
Hymen, medico-legal importance of the, 678.
Hyoscyamine, in the treatment of the insane, 608; poisoning by, 216.
Hyperemesis gravidarum, 556.
Hypnone, the physiological and therapeutical action of, 357.
Hypnotic, anæsthesia, 260; antifebrin as a, 199; a new, sulfonal, 597; strychnine as a, 455.
Hypnotism, and natural sleep, 362; therapeutic value of, 19.
Hysterectomy, for fibroids, a good showing for, 484; vaginal, 164; vs. Apostoli's method, 551.
Hysteria, pulmonary, 692.
Hysterical coma, a case of, 273.
Hysterical fever, 466.
Hystero-trachelorrhaphy, some of the simple methods of performing, 573.

I

Icterus neonatorum, the pathology of, 693.
Ileo-cæcal valve, treatment of inflammation in the region of, 553.
Indiana State Medical Society, 702.
Indigestion and lithiasis in the neurotic, 3.
Inebriates, American Association for the Cure of, 706.
Inebriety, mental responsibility in, 189.
Infant feeding, 617; report of sub-committee of the American Medical Association on, 527.
Infant, small scarf-pin swallowed by, 665.
Infantile diarrhœas, classification and treatment of, 246.

Infection, a possible carrier of, 242 ; how to prevent the spread of, 125.
Infectious and infective diseases, pathology of, 583.
Infectious diseases, and putrefaction, 55 ; transmission of, through the medium of rags, 126.
Insane, commitment of the, 157 ; composite portraiture of, 23 ; hyoscyamine in the treatment of the, 608 ; of New York, care of, 195 ; of New York, their care, and measures for their commitment, 75 ; State care of the, 274.
Insanity, and uterine disease, 15 ; emotional, 647.
Insomnia, hot baths for, 708 ; strychnine in, 139.
Instincts, natural, of educated women, 43.
Instruments, surgical, aseptic cases for, 124.
Insufficiencies of the ocular muscles, 81, 138, 256, 286, 343.

Intestine, large, paralysis of, simulating peritonitis, 382.
Intestines, injuries of, diagnosis by insufflations of hydrogen gas, 562.
Intra-nasal plug, the, 14.
Intra-uterine medication, nature and dangers of, 23.
Intubation of the larynx, for the relief of acute œdema glottidis, 499 ; asphyxia from obstructed tube, 198 ; in Germany, 536.
Intussusception, acute, in an adult, 382, 393.
Inunction, the value of, 633.
Invention, surgical, shall it be patented ? 313, 400, 454.
Iodine, a good way to give, 672 ; in ascites, 584 ; trichloride of, 356.
Iodoform, germicidal properties of, 47.
Iodol as a substitute for the iodides and iodoform, 415.
Iron, bromide of, the therapeutic properties of, 637 ; in purpura, 428 ; the liver the excretory organ for, 609.
Ischio-rectal fossa, gangrene of, 294, 312.
Italian Surgical Congress, 445.
Itch, epidemic winter, 43 ; divers species of, 494 ; winter, 257.

J

Jaborandi in snake-bites, 19.
Jacobi, Dr. Mary Putnam-, notice of book by, 672.
Jacobs, Dr. C. C., resection of the femur for ununited fracture, 38.
Jambul in diabetes, 174.
James, Dr. M. B., the micro-organisms of malaria, 269.
Jamieson, Dr. W. Allan, notice of book by, 644.
Jaundice, catarrhal, the modern pathology and treatment of, 332.
Jefferson Medical College and educational progress, 696.
Jenks, the William F., memorial prize, 196.
Joint-disease, operative treatment of, 167.
Joints, inflamed, antiseptic injection of, 583.
Jones, Dr. E. J., two cases of foreign bodies, 201.
Judson, Dr. A. B., orthopedic treatment of paralysis of the anterior muscles of the thigh, 118.

K

Kallay Dr. A., thanks to American physicians, 427.
Karyokinesis, 99.
Keen, Dr. W. W., on the conditions conducive to the earliest possible healing of operation wounds, 85.
Kell, Dr. J. B., antifebrin as a hypnotic, 199 ; a peculiar case of foreign bodies in the alimentary canal, 273.
Kibler, Dr. C. B., laparatomy for typhlitic abscess, 633.
Kidney, cystic degeneration of, 77 ; floating, nephrorrhaphy for, 613 ; primary tuberculosis of, 77 ; diseases, relation of, to heart diseases, 485 ; removal of tuberculous, 3 ; ruptured, 49.
Kilbourne, Dr. H. S., a case of chronic membranous enteritis, with periodical exacerbations, 199, 664.
Kinnicutt, Dr. Francis, on the chemical examination of the gastric secretions for diagnostic and therapeutic purposes, 598 ; pyloric stenosis due to ulcer, acute intussusception in an adult, paralysis of the large intestine, 382.
Kinnier, Dr. D. F., chronic atrophic spinal paralysis in children, 295.
Kitchen, Dr. J. M. W., an effective nasal syringe, 483 ; the flesh-brush a remedy for winter itch, 454 ; the intra-nasal plug, 13.
Klaphel, Dr. Buchanan, xeroderma pigmentosum, 621.
Kolpo-urethro-cystotomy, 646.
Kremyanski's treatment of phthisis, 610.

L

Labor, premature, is it justifiable to provoke, for restoration of sight in albuminuric retinitis ? 239.
Laboratory instruction in medical colleges, 418.
Lanolin in cuts and burns, 642.
Laparotomy, cases of intestinal obstruction treated by, 205, 225 ; for acute suppurative peritonitis, 174 ; for dilatation of the colon, 636 ; for rupture of the uterus, 281, 307 ; or enterostomy ? 233 ; treatment of peritonitis by, 16.
Laparotomies, American, statistics of, 223 ; report of 79, done in 1887, 345.
Laryngectomy, mortality from, 474.
Larynx, epithelioma of, 368 ; extirpation of the, 45, 421 ; intubation of, 198, 499, 536.
Las Vegas, N. M., the health of, 469.
Latin in prescriptions, 716.
Lawrence, Dr. R. R., fatal obstruction of the bowels, with peculiar features, 198.
Lawson Tait's method in plastic operations, 428.
League, the sanitary protective, 587.
Lectures, clinical, property in, 364.
Le Fort, Leon, book notice, 102.
Legal case, an interesting, 481.
Leprosy in the United States, and its relation to the State, 251.
Letter, Canada, 285 ; London, 26, 79, 136, 169, 229, 255, 312, 341, 370, 399, 426, 480, 510, 565, 594, 648, 677, 702 ; Paris, 27, 80, 228, 285, 479, 566, 595.
Leucocythæmia, is it cancer of the blood ? 372 ; thyroidic, 476.
Leyden's crystals without asthma, 39.
Lichty, Dr. D., a possible carrier of infection, 242.
Life, the lesson of a, 472.
Ligaments, pelvic, puerperal relaxation of the, 244.
Limping, the value of, as an aid to diagnosis, 88.
Linea alba, extra-peritoneal incisions in the, for the purposes of exploration, 158.
Lip, cancer of, non-recurrence after excision, 311.
Lipanim, 335.
Liquor amnii and fœtal nourishment, 568.
Lithæmia, and neurasthenia, 284 ; sulphocyanide of potassium in, 555.
Lithiasis and indigestion in the neurotic, 1.
Lithium carbonate, administration of, 635.
Litholapaxy in male children, 40.
Litholysis, experimental observations on, 513.
Lithotomy, 113.
Liver, abscess of, specimen of, 78 ; cirrhosis of, some interesting clinical phenomena observed in a case of, 579, 593 ; gummatous tumors of, 367 ; hydatid disease of, incision of the cyst in, 551 ; hydatid cysts of, treatment of, 448 ; innervation of the, 611 ; non-calculous suppuration of, 584 ; physiological variations in the position and shape of, 428 ; removal of a portion of the, 637 ; resection of left lobe of the, 216 ; ruptured, 49 ; the excretory organ for iron, 609.
Lockwood, Dr. George Roe, impacted renal calculus, with the report of a case, 576.
"Loco" plant, 197.
Lomb prize essays, 501.
Loney, Dr. D. W., an obscure case, 663 ; naphthol in stomatitis, 664.
Long life without exercise, 478.
Longevity, conditions of, 390 ; relative, of Americans and English, 46 ; remarkable hereditary, 175.
Loomis, Dr. Alfred L., anniversary address before the Medical Society of the State of New York, 14.

Skoda, Dr., death of, 391.
Sleep, natural, a new interpretation of, 362.
Small-pox, calomel in the prevention of pitting from, 67; has a person who is not susceptible to vaccinia immunity against? 705.
Smith, Dr. A. A., some clinical points on gastrectasia, 120.
Smith, Dr. A. Noel, gall-stones or soap? 215.
Smith, Dr. Eustace, notice of book by, 643.
Smith, Dr. Gouverneur M., wasted sunbeams—unused housetops, 429.
Smokers' vertigo, 605.
Snake, digestion and temperature of the, 174.
Snare, nasal, a modified, 315.
Society practice and its abuses, 669.
Sodium, benzoate in uræmia, 130; bicarbonate in membranous croup, 243; sulphobenzoate in the dressing of wounds, 156.
Solanin, actions of, 40.
Solvine, 455.
Somniferin, 392.
Sozoiodol, a new dermatological remedy, 372.
Spalding, Dr. James A., is vision ever permanently affected by sunstroke? 464.
Sparteine, action of, 389; in cardiac affections, 56, 666.
Spencer, Dr. William C., death of, 364.
Spicer, Dr. Scanes, notice of recording forms by, 643.
Spinal cord, changes of, after temporary occlusion of the abdominal aorta, 637; local medication of, 291.
Spinal paralysis, periodical, 667.
Spinal tumor, successful removal of, 224.
Spiritism, a victim of, 390.
Spleen, excision of a dislocated, with expectoration of the ligature of the pedicle, 709; ruptured, 491
Splenectomy, 174.
Squire, Dr. T. H., shall a surgical invention be patented? 454; unusual case of cancer, 327.
Squires, Dr. G. W., detachment of the placenta before the birth of the child, 13; evacuation of mammary abscesses through their natural outlets, 607.
Stedman, Dr. Thomas L., the value of limping as an aid to diagnosis, 88.
Steno's duct, passage of a hair into, causing an abscess and fistula, 519
Stenosis, pyloric, a successful operation for, 698.
Sterility, and gonorrhœa, 20; in the male, 176; in the male, frequency of, 202; Pajot on, 79.
Sterilized dressings, 666.
Sternum, enchondroma of, 367.
Stethoscope, a new, 678.
Stevens, Dr. George T., a phorometer, 511; insufficiencies of the ocular muscles, 138, 256, 343.
Stewart, Dr. J. O., a bullet which had passed through the abdominal wall discharged per anum, 608.
Stewart, Dr. John S., notice of book by, 643.
Stilwell, Joseph A., for the cure of winter itch, 510.
Stimulants in the treatment of skin-diseases, 216.
Stokvis, B. J., book notice, 103.
Stomach, acute dilatation of the, 708; dilatation of, 120, 133, 230; disease of, diagnosis and treatment of, 591; Loreta's operation on, 551, 698; significance of hydrochloric acid in the diagnosis of disorders of the, 471; stone in the, 217; washing, ethics of, 559; washing in children, 220.
Stomatitis, in milk, 359; mercurial, mercury in the cure of, 361; naphthol in, 664.
Strang, Dr. Albert, death of, 130.
Street, Dr. Thomas W., gall-stones or soap? 413.
Stricture, urethral, modern treatment of, 100; treatment of, by electrolysis, 655, 674; treatment of, by rapid dilatation, 637.
Strophanthus, 246.
Strychnine, as a heart stimulant, 202; as a hypnotic, 455.
Subinvolution, uselessness of ergot in, 111, 650.
Sublimate solutions, the addition of an acid to increase their antiseptic power, 217.
Sulphates, nitrates, and chlorides, comparative antiseptic values of, 552.
Sulphonal, 560, 597.
Sulphur in chlorosis, 156.
Sulphur waters in laryngeal phthisis, 84.
Sulphurous acid in the treatment of pulmonary consumption, 358.
Sunbeams, wasted, 429.
Sunstroke, vision permanently affected by, 464, 664.
Superfecundation, 20, 201.
Suppuration and septic diseases, 415.
Suprarenal capsules, the function of the, 330.
Sure cures and specifics, 169.
Surgeon-general of the army, report of the, 18.
Surgical instruments and appliances, the duty on, 102.
Surgical invention, shall a, be patented? 313, 400, 454.
Suspended animation from anæsthetics, inversion of patient in, 63.
Suture-fastener for silver wire, 673.
Suzor, Dr. Renaud, book notice, 103.
Swasey, Dr. E. P., penetrating wound of the neck, involving the common carotid artery and internal jugular vein, 197.
Sweat-glands, some studies on, 722.
Swett, Dr. W. P., insufflations of quinine in whooping-cough, 14.
Swift, Dr. Thomas D., notice of death of, 307.
Swine, a new disease affecting, 101.
Syphilide, a case of recurrent macular, 520.
Syphilis, abortive treatment of, 613; and carcinoma, 193; are the tertiary products of, infectious or not? 484; auto-inoculation of, 590; calomel and inunctions of mercury in, 259; congenital, contribution to the etiology of, 330; congenital, hypertrophy of the skull in, 245; congenital, the teeth in, 10; constitutional, the occurrence of, without other than initial symptoms, 629; hereditaria tarda, 395; limit of contagious period of, 589; new microbe of, 43; re-infection of, 589; salicylate of mercury in, 358; treatment of, during the primary stage, 309; treatment of, in Vienna, 69.
Syphilitic myositis, 244.
Syphilitic ulcerations of the female urethra, 300.
Syringomyelia, 508.

T

Tachycardia, paroxysmal, 11.
Taft, Dr. Charles E., report of a case of tubal pregnancy advancing to full term without rupture, 209.
Tait, Mr. Lawson, on Dr. Thomas' case of tubal pregnancy advancing to full term without rupture, 400.
Taylor, Dr. George H., notice of book by, 643.
Taylor, Dr. R. W., xeroderma pigmentosum and its relation to malignant new-growths of the skin, 261.
Taylor, Dr. W. V. M., protecting the perineum, 201.
Tea-drinking, dryness of the throat from, 82; relation of, to nervous disorders, 40.
Teeth in congenital syphilis, 10.
Temperature of our food and drinks, 130.
Temperature sense, 259.
Tennessee State Medical Association, 444.
Tension, hyperarterial, and its treatment, 557.
Terebene, pure, in uterine cancer, 201.
Terebinthine bath, a cheap and effective, 242.
Terpine in diseases of the lungs, 711.
Testicles, diseases of, and operations on, 547.
Testis, tuberculosis of the, 229.
Tetanine, 559.
Tetanus, 84; and erysipelas, 505.
Thallin in gonorrhœa, 244.
Theobald, Dr. Samuel, notes of two cases of reflex paralysis of accommodation of the eye, with mydriasis, due to dental irritation; with observations upon their supposed bearing on the question of the pathogenesis of sympathetic ophthalmitis, 211.
Thermometer, the best, for physicians to use, 639.
Thigh, osteoplastic amputation of the, 665.
Think, the time it takes to, 258.
Thomas, Dr. D. O., puerperal sepsis, 686.
Thompson, Dr. J. L., is it ever justifiable to provoke premature labor for the restoration of sight in albuminuric retinitis? 239.
Thomsen's disease, an atypical case of, 433, 451.

Thomson, Dr. W. H., combination of cardiac neurotics, 541.
Thoracoplasty for empyema, 447.
Thornton, Dr. W. F., some of the reasons why quarantine is not a success, 482.
Thyroid gland, the function of the, 521.
Tight lacing, effect of, on the flow of bile, 420.
Tinnitus aurium, nitro-glycerine in, 612.
Toad-fish, fatal poisoning from, 82.
Tobacco habit, 247.
Tobacco vertigo, 632.
Tongue, cleft, specimen of, 109; hypertrophy of glandular tissue at the base of, 171; imaginary ulcers of, 42; in disease, 442.
Tonsil of the tongue, hypertrophy of the, 133.
Tonsillitis, phlegmonous, death by suffocation in, 215.
Tonsils, enlarged, galvano-puncture for, 162.
Trachoma among the negroes in the United States, 342.
Trumbull, Dr. John, the cholera in Chili, 712.
Tubal pregnancy advancing to full term, 209, 400.
Tubercle bacilli, simple and rapid staining of, 631.
Tubercular pleurisy, spontaneous cure of, 665.
Tubercular ulceration of the nose, 655.
Tuberculosis, blood in, 20; bovine, 163; experimental investigations of, 614; therapy of, 701; transmission of, by the respiratory passages, 312.
Tuberculous joints, resection of, and general tuberculosis, 260.
Tumor, cerebral, 106.
Turbinated bones, posterior hypertrophies of, cautery-snare for removal of, 315.
Turpentine in diphtheria, 127.
Tuttle, Dr. F. A., vision permanently affected by sunstroke, 664.
Tynberg, Dr. S., swallowing pennies, 13.
Typhlitic abscess, laparotomy for, 633.
Typhlitis, 561; pathology and clinical types of, 302.
Typhoid bacillus, recent studies of the, 359.
Typhoid fever, and pregnancy, 580; and sewer-gas, 278; etiology of, 203; immunity of the Chinese from, 537; with some peculiar features, 200.

U

Ulcer, gastric, some curious relations of, 706; pyloric stenosis due to, 382, 393.
Ulcers, chronic, treatment of, 667.
Umbilical phlegmon, 254.
Umbilical tumor in an infant formed by prolapse of intestinal mucous membrane of Meckel's diverticulum, 431.
United States, progress in medical education in the, 129.
Uræmia, benzoate of soda in, 130.
Urea centre, 391.
Urethra, dilator of the, 675; female, syphilitic ulcerations of, 300; stricture of, treatment of, by electrolysis, 655, 674.
Urethral, sound, a dilating, 171; stricture, formation of, 31; stricture, treatment of, 33; strictures, the modern treatment of, 100.
Urethritis, gouty, 288.
Uric acid, calculi, the problem of dissolving, 303; concretions, solvent treatment of, 280; elimination of, by the skin, 40; pathology of, 609; tests for, 40.
Urinary organs, some points in the surgery of, 29, 57, 113.
Urinary paraplegia, 362.
Urine fever, 29.
Urticaria, hydatid, pathogeny of, 284.
Uterine diseases and insanity, 15.
Uterus, and its appendages, displacements and inflammations of, nervous symptoms arising from, 177; cancer of, a new symptom characteristic of, 580; cancer of, pure terebene in, 201; carcinoma of, 449; electrical treatment of disease of, 625; fibroid tumor of, 367; fibroid tumors of, a new method of supplying the continuous or galvanic current in the treatment of, 356; fibroid tumors of, hemorrhage due to, the use of the curette for the relief of, 90; gravid, penetrating wounds of the, 203; laparotomy for rupture of, 281, 307.
Uvula- and palate-retractor, a self-retaining, 54.

V

Vaccination against septicæmia, 275.
Vaccine and variola, 53.
Vaginal examinations, lubricant for use in, 624.
Vaginal pressure in chronic pelvic disease, 636.
Valentine, Dr. F. C., notice of book by, 644.
Valvular disease, failure of the heart in, and its treatment, 305.
Vander Veer, Dr. A., obstruction of the bowels due to adherent diverticulum, 62.
Van Horne, Dr. Andrew B., notice of death of, 444.
Van Santvoord, Dr. R., two cases of Raynaud's disease, 35.
Van Stavesen, Dr. W. B., the pathological importance of the nose, 343.
Vaso-constrictors, observations on some, 258.
Vaso-motor disease, a rare form of, 657.
Veratrum, action of alkaloids of, 39.
Veratrum viride, in diphtheria, 627; in puerperal convulsions, 329.
Vermiform appendix, diseases of, 720.
Vermilye, Dr. William E., notice of death, 160.
Version before labor in malpositions of the fœtus, 581.
Vertigo, smokers', 605; tobacco, 632.
Vice, regulation of, 652.
Virchow on cancer, 195.
Vision permanently affected by sunstroke, 464, 664.

W

Wagner, Professor E., notice of death of, 334.
Waiter's cramp, 22.
Waldron, Dr. M. M., oxalate of cerium in sea-sickness, 704.
Ware, Dr. H. B., a new antiseptic ligature reel, 111.
Warren, Miss Lillie E., teaching the deaf in the public schools, 704.
Water, bacteriological tests of, 304.
Watt, Dr. Andrew, a case of myxœdema, 97.
Way, Dr. J. H., a case of death by suffocation in phlegmonous tonsillitis, 215.
Weil's disease, 689.
Weir, Dr. Robert F., on the technique of the operations for the relief of intestinal obstruction, 147.
Welch, Dr. William H., the general pathology of fever, 373, 401, 457.
Wells, Dr. Edward F., dilatation of the stomach, 230.
Wells, Sir T. Spencer, on the electrical treatment of disease of the uterus, 625.
Wendt, Dr. Edmund C., sulfonal, a new hypnotic, 597.
Wetherby, Dr. B. J., antipyrin in acute and painful eye affections, 200.
Whiff, the oral, 235, 427.
White, Dr. George, a pin lodged in the pharynx, 387.
White, Dr. Howell, shall surgical inventions be patented? 371.
White, Dr. J. Blake, the hypnotic action of antipyrin, 260.
Whittlesey, Dr. Francis P., a case of intestinal obstruction caused by a diverticulum, 242.
Whooping-cough, bacillus of, 69; benzol in, 15; grindelia robusta in, 74; insufflations of quinine in, 14.
Wilmer, Dr. William H., levelled abducting prisms, 316.
Wilson, Dr. J. C., notice of book by, 419.
Winter eczema, treatment of, 388.
Winter-itch, 257, 427; epidemic, 43; flesh-brush a remedy for, 454; treatment of, 510, 707.
Witherle, Dr. C. B., sulphide of calcium in pulmonary phthisis, 12.
Woman, the physical progress of, 304.
Women, educated, natural instincts of, 43.
Wood, Dr. Charles S., some points in the treatment of chronic albuminuria, or Bright's disease, 320.
Worcester, Dr. William L., the mortality of epilepsy, 467.
Wormian bones in fontanelles and their effect in childbirth, 412, 424.
Wounded, how to remove the, 652.
Wounds, dressing of, sulpho-benzoate of soda in the, 156; mode of entrance of micro-organisms into, 693; operation, conditions conducive to the earliest possible healing of, 85; poisoned, treatment of, 39.
Wright, Dr. Jonathan, a modified nasal snare, 315.
Wrist, resection of, 421.
Wylie, Dr. W. Gill, a year's work in abdominal surgery, with a report of seventy-nine laparotomies done in 1887, 345.

X

Xeroderma pigmentosum, 621; and its relation to malignant new-growths of the skin, 261, 281.

Y

Year-book of treatment for 1887, 642.
Yellow fever, inoculations of, 502; microbe of, 622, 680.
Yount, Dr. Silas T., notice of book by, 643.

Z

Zona, treatment of, 631.
Zulch, Dr. Gustavus, a case of ovariotomy, 14.
Zweifel, Dr. P., book notice, 104.

A STUDY OF THE ARTERIES AND VEINS IN BRIGHT'S DISEASE.[1]

By ARTHUR V. MEIGS, M.D.,

PHYSICIAN TO THE PENNSYLVANIA HOSPITAL, PHILADELPHIA.

For some time past my clinical observations made annually in the wards of a large general hospital have led me to feel how unsatisfactory is our present understanding of the cause of many forms of heart disease, and of the mode of origin of Bright's disease, and at the same time how difficult it is to arrive at a satisfactory understanding of a case in which these two apparently far apart diseases are, as so commonly happens, coexistent. The intimate relation of disease of the two organs is so well known that for some years medical literature has been filled with various theories to explain how the one is dependent upon or caused by the other. As a result of the observations of Bright it soon became well known that hypertrophy of the heart—and it was said of the left ventricle in particular—was very commonly associated with disease of the kidney; and naturally enough it was thought, as the clinical history of such cases demonstrated the existence of kidney disease long before that of the heart became known, and often the heart disease was not suspected at all before the autopsy was made, that the heart disease was entirely dependent upon, and caused by, that of the kidney, and complicated theories were brought forward to explain how the train was set in motion, and the various steps from its inception to its final development. Soon clinical medicine demonstrated that in many cases in which the coexistence of heart and kidney disease was undeniable the history occasionally proved beyond peradventure that heart disease had existed before there was any suspicion, much less evidence, of disorder of the kidney. New theories were required to explain this condition, and they were soon found, principally in the results of congestion of the internal organs, and of the kidneys in particular it was assumed, which was a necessary result of disordered action of the heart. Another step was the observation that the two organs—heart and kidney—are connected by an immense vascular highway, the arterial system, which was found in many instances to partake in the disease; for atheroma of the arteries, more or less extensive, is a common accompaniment of combined heart and kidney disease. Parenthetically it may be observed here that it is curious that comparatively little is to be found in medical literature in regard to the state of the venous system, either in the form of study of its physical condition, or of theory in regard to what might be expected to happen to the veins, though the rest of the subject has been from many points of view somewhat overloaded with theories. This is strange, when it is recollected that the venous highway connecting the two organs is just as large and fully as important as the arterial. The observations of Dr. George Johnson of the hypertrophy of the muscular coat of the arteries of the kidney, and later of the same hypertrophy in various other tissues and organs in cases of red granular contracted kidney, and those of Virchow of the state of the arteries in amyloid disease, constitute important landmarks in the development of our knowledge of the whole subject, and this though there has been, and is, great difference of opinion in regard to the interpretation of the various facts observed. The paper of Gull and Sutton upon the so-called arterio-capillary fibrosis was the first systematic attempt to show that many cases which had previously been called Bright's disease of the kidney were, in truth, due solely to changes which had their origin in the arteries and capillaries, and in the connective tissue in which they lie. This was a bold step in advance, and has done much toward leading to a clearer comprehension of the complaint by ridding the minds of pathologists of the idea that the disease was Bright's disease of the *kidney*, and that in that organ alone must they dare to seek for the original source of the pathological train. The observations of Gull and Sutton, though of great value in thus clearing the atmosphere of this old doctrine, have not been borne out in other respects by subsequent and more extended observations. Their assertion that the origin of the vascular changes is to be looked for in the adventitia of the arteries and in the capillaries can hardly be considered to have been substantiated. With regard to capillaries our present means for their study are not satisfactory, and little has been even asserted, up to the present time, of their diseases, except that in some cases it has been considered that the walls of the Malpighian tufts of the kidneys were thickened, and again, that there was in various organs increase of the perivascular connective tissue. So far as the first assertion is concerned—that the walls of the Malpighian capillaries are thickened—it cannot be considered as having been proved, though it is exceedingly likely; and for the increase of connective tissue it yet remains to be demonstrated that this is a part of, or even due to, the capillaries, with regard to the real physical condition of the walls of which we are still somewhat in ignorance. No attempt to study the condition of the capillaries in dead tissues, further than to trace their course, has as yet yielded any conclusive results. Nor has it by any means been demonstrated that the changes so extensively found in the arteries and arterioles have their origin in the adventitia.

The present state of knowledge of the complaint seems to be about as follows: It has long been known that in cases of albuminuria certain physical changes take place in the kidney, and that very commonly there is enlargement of the heart, and further, often there is atheroma of the larger arteries, which is more or less extensive as the case may be. It has, besides, been demonstrated that other changes, chiefly of a degenerative or atrophic nature, are found in many of the various organs and tissues of the body—namely, disease of the cerebral arteries, and of the arteries and substance of the spinal cord,[1] emphysema and slow inflammatory processes in the lungs, calcareous and allied forms of disease of the heart valves, degenerations of the coronary arteries, and fibroid change of the muscular substance, and various forms of disease of the liver and spleen. Such being the case, quite a number of the medical minds that have bestowed attention upon the subject have been struck with the idea, and have enunciated the belief that this hydra-headed disease, or collection of related diseases, as the event may prove it to be, had its origin in the arteries or capillaries, or both, though no one has as yet shown what the mode of origin is; Dr. Johnson, and those of his school, believing it to be one of the so-called blood-diseases which produces its first physical change in the secreting cells of the kidney, while Gull and Sutton, and their following, equally strenuously uphold the opinion that the disease has its origin in the adventitia of the arterioles, and in the capillaries and perivascular connective tissue.

[1] Gull and Sutton: On Changes in the Spinal Cord and its Vessels in Arterio-capillary Fibrosis, Trans. Path. Soc., London, vol. xxviii., 1877.

The utter inadequacy of a diagnosis of valvular disease of the heart, or Bright's disease of the kidney, in cases of this nature, as at all descriptive of the real conditions, has pushed itself upon me so forcibly of late years that I have been in the habit of saying, and recording in my clinical histories, that these cases were of vascular origin. Sometimes it seems like the natural result of the advance of years, the machinery wearing out simply because it is too old; or, again, it is as if premature old age came upon the patient, or perhaps he is worn out by dissipation, or because he has earned his livelihood by some physical labor so severe that it necessarily speedily exhausts his vital forces and produces the physical disorganization. The absurdity of the old practice of endeavoring to elicit a history of rheumatism, and then, if the slightest account of joint pains during the past life could be had, of attributing the disease to that, I have long looked upon as the weakest explanation. It is now well known that rheumatism, instead of being, as was formerly thought, almost the sole cause of valvular disease of the heart, is but one of many, all of which are equally capable of producing it. Dr. Allbutt[1] long ago, in an able article, expressed his opinion that, in the large manufacturing town in England in which he lived, heart diseases in hospital practice were much more common among young men as the result of overexertion of the body than of acute rheumatism.

As clinical study has seemed to do little for me in the direction of showing what is the original physical change or pathological basis of the disease, but has merely taught me to be able to predict, with a good deal of accuracy, that, in addition to the well-known lesions in the heart and kidneys, other very widely diffused changes will be found if sought for after death, I have turned from the wards to the post-mortem room in the hope that thus some light might be shed upon the subject. In this way I have been led to the observation of facts which, I trust, may be worthy of the consideration of the profession. It is with a profound sense of the wisdom of Sir James Paget's observation,[2] that "medicine and surgery are eminently a science of observation; deductions from facts are always unsafe; I believe that they have done far more harm than good; and, for the most part, when sufficient facts have been collected and arranged, the general conclusions that may justly be drawn from them are nearly manifest," that I attempt to describe what I have seen. If I should be led into making deductions, and few men can resist the inclination, which seems a natural one to thinking beings, the already quoted wise saying must be remembered, and a sharp line drawn between that which is a result of observation and therefore fact, and what is merely theory or deduction.

The first things that strike one who reflects upon this combination of heart and kidney disease is the intimate connection there is between the two organs by the vascular system, the arteries and veins, and that if the disease begins in one organ and extends to the other, this must be the channel of communication; or that perhaps it does not originate in either, but in the blood-vessels, and secondarily extends to the organs. This latter preconception is rendered still more probable when it is remembered that degenerative changes parallel to those found in the heart and kidneys exist in many other organs and tissues, and it therefore becomes much more easy to believe that the vascular change is the cause and not the consequence. In pathological investigation, therefore, with a view to further elucidation in regard to the original cause, my mind has been occupied with the preconceived idea that the search must be prosecuted by study of the physical conditions of the arteries and veins, and perhaps the capillaries. This statement is made with the knowledge that wherever blood-vessels go they are accompanied by nerves, and that it is possible, and from a purely theoretical stand-point as likely, that the pathological lesions under discussion originate in the nerves as in the blood-vessels. Drs. Da Costa and Longstreth[1] have asserted that in Bright's disease there is a constant lesion of the renal nerve plexus, and have expressed their opinion that this lesion is the cause of the kidney disease, and have further suggested that a similar lesion may exist in other ganglia producing parallel effects, as, for instance, in the cardiac plexus, causing the hypertrophy of the heart. Though this is of course an explanation which may be correct, it has been by no means proved, and even if extended investigation should show nerve-lesions to be as constant a feature as are the blood-vessel changes, it remains to be discovered which, if either, is the real original cause, for upon purely hypothetical grounds the two are perhaps equally acceptable.[2]

In making somewhat extended post-mortem investigations the lesion I have found to be most constant and most extensively distributed throughout the tissues is disease of the arteries and arterioles, a condition in which, so far as my observations have carried me up to the present time, though I confess that the study has not as yet been exhaustive, the veins seem to participate. In regard to the condition of the capillaries I have nothing to say, for, as already stated, there is no known satisfactory method of studying their physical condition in dead tissues. It is a commonly recognized fact that in cases of the so-called Bright's disease there is ordinarily present a greater or less amount of atheroma of the larger arteries; and Johnson upon the one hand, and Gull and Sutton on the other, and when these names are mentioned it must be understood that all other observers who have either preceded or followed them in the same lines of investigation are included, have made extensive observations in regard to the state of the minute arteries in many of the organs and tissues of the body. Their conclusions have been quite different from those reached by me, though in the course of my investigations I have fallen upon appearances similar to those they have described. I have made sections from the brain, spinal cord, lungs, heart, liver, spleen, kidneys, and of various of the larger arteries and veins, and in all of them—except the spinal cord, and with regard to its condition my examinations have not been sufficiently numerous to be conclusive—have found quite constantly present an irregular overgrowth and thickening of the intima of the arterioles. This thickening varies very much in its anatomical characters and its extent, and often when it is present in high degree there is involvement of the other coatings, though ordinarily they have undergone no change. The morbid appearances will be better understood from an examination of the plates than would be possible from any written description. The condition appears to be nothing but that which is described in text-books of pathology as the various forms and stages of atheromatous change, but observers do not seem to have connected its existence with this disease further than to have noted that it was commonly present in the larger arteries. The appearances found differ much in accordance with the size of the vessel in which they are observed, and in different organs. In larger-sized vessels the more commonly understood atheromatous changes will most usually be found—misshapen vessels, calcareous deposits, loss of substance of intima, thickened patches upon the inner surface (these being often so extensive as to cause great obstruction to the blood-current, sometimes the lumen of the vessel being a mere chink at one side; see plate, Fig. 5), and where the condition has progressed to its full development, more or less destruction or alteration of the entire thickness of the walls. In smaller ones the changes are most commonly confined to increased thickness of the intima, which is not usually so irregular in degree at different portions of the circle as is the case in large arteries, though it is seldom absolutely uniform. The intima in such vessels, when examined in cross section, often has a thickness which will be half as great as, or even equal to, that of the muscular coat, but it may vary to almost any extent. This tissue, when examined under the microscope, appears to be composed of fibrous material, the fibres of which, when the vessel is viewed in cross section, appear to be circular, and in longitudinal sections to run lengthwise; there are, therefore, probably abundant fibres running in all directions, thus giving the tissue considerable strength. Contrary to what is commonly stated, I have usually found this morbid tissue to contain here and there numerous nuclear elements. In the larger vessels in particular, and where the patches of atheromatous thickening are large, they are often composed of a well-organized tissue containing numerous cells, which in their appearance and arrangement resemble granulative tissue, seeming disposed to arrange themselves in nests, as is common in young and rapidly growing tissues.

[1] Da Costa and Longstreth: Researches on the State of the Ganglionic Centres in Bright's Disease, American Journal of the Medical Sciences, July, 1880.

[2] Since the above was written Dr. Da Costa has published another paper upon this subject, giving the results of microscopic examination of the cardiac ganglia in cases of Bright's disease, and announcing that extensive organic changes were found—The Middleton Goldsmith Lecture on the Relation of the Diseases of the Kidney, especially the Bright's Diseases, to Diseases of the Heart—Medical News, May 5, 1888.

The well-organized cellular outgrowth of the intima in these cases is identical with that which has been most frequently described as syphilitic endarteritis, and yet I have seen it in a number of cases in which there was neither a history of syphilis nor reason to suspect the existence of that disease. Examination of the endocardium and valves of the left heart often shows a condition precisely parallel to, and seemingly a part of, the same process, the evidences of which exist so extensively in the arteries. It seems positive that the endocardial and endarterial changes are but part of the same disease, and that this is the cause of the valvular changes which so frequently arise, complicating the trouble, and, when they exist, much hastening the inevitably fatal result. In examining the thickened patches of endocardium, and in sections of aortic valve flaps, thickened and distorted by the disease, there were found the same nest-like arrangements of cells described as existing in the intima of the arteries.

While the above-described conditions are those I have usually seen as a result of examination of the arteries, I have not, as a common thing, found the increased thickness of the muscular coat which is described by Johnson, and called by him a hypertrophy, to be present in such degree as to render its existence undoubted. Arteries may often be found in which it could be said that the middle coat was unduly thick, and, again, others, in regard to the state of which there might be dispute, but in most instances I have failed to find an increase so great that its existence could be considered to be beyond doubt. It is a much easier matter to be sure that the appearances described of the intima are morbid; for, in the natural state, in small vessels certainly, it constitutes but a very thin layer, and besides, when it is seen to be many times thicker, as happens in many instances, upon one side of transverse section of an artery than upon the other, there cannot be a shadow of doubt that such an appearance is pathological. This is very different from what is found in regard to the muscular coat, which, if at all thickened by disease, is uniformly so, and there is, therefore, nothing to contrast it with, and its state can be merely estimated as a matter of judgment. It is curious that in one case in which I made many sections (case of J. K——) of different organs and vessels, the only artery in which there was undoubted thickening of the muscular layer was one of the primary branches of the renal. In this vessel the intima was thickened to a slight degree, but much more so at some parts of the circle than at others, and the plicated membrane very distinctly visible around the entire circuit; the muscular coat, however, which was probably of twice the ordinary thickness in a vessel of such size, did not present the appearances which could be called those of true hypertrophy; for, although the muscle bands and nuclei were present and numerous, there were also visible very many other cells which were exactly like those described as so commonly found in the overgrown intima. These cells were, so to speak, wedged in between the muscle elements, and many of them were undergoing pigmentary degeneration. Sections of the abdominal aorta in this case, and of the minute arterioles in the renal substance itself, did not show any indisputable increase of the muscular coat, though there was in both overgrowth of the intima. To anyone who would wish to advocate Dr. Johnson's view, that increased thickness of the muscular layer is a true hypertrophy, and that it increases what he calls the "stop-cock" power of the arterioles, does it not seem strange that the only artery that showed undoubted increased thickness of the middle layer in this case should, in that very layer, present the marked evidences of a degenerative process, and that the vessel affected should be a very large one, to which, ordinarily, is attributed elasticity and not much contractility, while the minute arterioles of the kidney, the very citadel of the supposed condition, should present none of it, and all the vessels in the neighborhood should have plainly thickened intimas?

Fig. 9 represents two views of a minute artery removed from a kidney under a dissecting microscope. The upper one is intended to produce the same effect as Johnson's ("Medical Lectures and Essays," by George Johnson, 1887) picture, from the appearances of which he makes his assertion of the existence of hypertrophy of the muscular coat. The vessel was carefully dissected out, then split open with scissors, and mounted with the inner side up, thus showing half of the internal surface of the vessel and the thickness of its walls at the cut edges. No fibrous coat is distinguishable, and the same holds good in Johnson's figures, but the muscular coat and intima are very well shown. Whether the muscular coat is increased or not I think might well be disputed, as this layer in the walls of an artery of such size is always a marked feature in a picture; that the intima is increased in amount, and, as represented in the picture, irregularly so, there can be no doubt, though it might be said that this is due to the crude method of preparing the object, to dissect it out and then cut it with scissors. That such is not the case, however, and that the intima is actually thickened, and irregularly so, is made very plain by the other picture. This is a bit of the same artery, and the section was prepared by cutting off from the end, before it was split open, as thin a section as could be made with a pair of scissors, and it very well shows the thickened intima lying within the plicated membrane, which latter is not distinguishable at all in the longitudinal section. To my mind it becomes evident from the contrast presented in these two pictures that the change of the intima is a much more positive and unmistakable one, and one which in the nature of things is capable of producing quite as grave effects as that of the muscular coat, upon the existence of which in this vessel doubt may be cast; a change also which, even if in other vessels its existence is undeniable, is accompanied by degenerative processes so extensive as to render its proper classification as a true hypertrophy uncertain.

So far as the "fibrosis and hyaline-fibroid" condition described by Gull and Sutton is concerned, I have failed to discover it in its full development. They declare their belief, and try to prove, that the vascular changes have their origin in the fibrous coat, and describe a high degree of thickening of the adventitia as being usually present. There can be no doubt that there is great increase of fibrous tissue, and it is found more extensively developed around the blood-vessels, the place in which connective tissue exists more abundantly than elsewhere in all organs; but its appearances are more those of a general increase of perivascular connective tissue than of the adventitia of arterioles alone. And for the matter of that, how is it possible to decide, in any section examined with the microscope, where the fibrous material lying outside the muscular coat of an artery ceases to be adventitia and becomes perivascular connective tissue? The two structures are identical and shade into each other without any defined boundary. Nothing that answered the description of hyaline-fibroid change of arterioles has come under my notice except certain appearances presented by the vessels in sections of the spinal cord; in the thoracic and abdominal viscera I have failed to find it, and cannot comprehend why this should be unless it is, as stated by Johnson ("Medico-chirurgical Transactions," vol. lvi.), that their methods were faulty and that the use of glycerine and camphor in mounting produced the appearances described. In the spinal cord I have found arteries with walls that looked entirely structureless except for a few nuclei lying at the edge of the lumen of the vessel, and answered exactly to the appearances described and figured by Gull and Sutton ("London Path. Soc. Trans.," *loc. cit.*). It might be well to mention here, as a matter of interest, though I have no explanation to offer, and do not know if it had any bearing upon the condition, that in this same case, which was one of marked Bright's disease, the olivary body, and nucleus dentatus within it upon the right side, was much larger than the left, though no morbid condition of the tissue itself could be discovered upon either side.

In two cases in which I made extensive microscopic examination of the tissues, and they are the two from which the vessels represented in the plates were taken, I found morbid changes in the veins as well as the arteries. Atheroma of veins so extensive as that of the femoral, which is shown in Figs. 7 and 8, is not usually described as being common, though the occasional occurrence of the disease in veins is sufficiently well known. After the section from which the picture is made was prepared, it was found impossible to determine with certainty, from the microscopic appearances alone, that the larger vessel of the two was really a vein, so great is the thickening of the intima and fibrous coats, and it was only by a careful examination of the piece of tissue from which the section was cut, and the discovery of a well-marked valve in the vein, that an absolute conclusion was reached. The two vessels, which were removed from the upper part of the thigh together, were found to be rigid, like bony tubes, and it was only after decalcification that sections of them could be cut. The process of disease in this vein appears to have been exactly the same as takes place in arteries, some thickening of all the coats, perhaps, for when considering the state of the muscular layer it must be remembered how thin it is in a natural condition in veins, and of the intima in particular. It is a noticeable fact that the thickening of the intima varies very much at different parts of the circle of the vessel, in this respect being precisely parallel to what has already been so much emphasized as occurring in arteries. The structure of the intima also appears to be similar in character to that found in arteries. How the two inner coats became loosened from the fibrous one, as appears in the plate, cannot of course be known; but it may be that the breakage occurred in removing the vessels from their position in the thigh, for so rigid were they that it required the exercise of some force to remove them.

Fig. 12 represents a portion of a vein lying in the adipose tissue covering the front of the heart, and presents a condition of which I have never seen any description. In most of it the walls are very thin and the tissue of a very loose texture, but in the intima there are two spots opposite each other in which marked cellular outgrowth has taken place and the cells have in the most distinct way arranged themselves in nests precisely like those described as existing in the arterial system. When this is examined with a higher power the arrangement of the cells can be still more plainly distinguished.

In most of the veins I have examined in this disease, what has struck me most forcibly in them has been the tenuity of their walls and the looseness of texture of the material of which they were formed. This can be seen to some extent with the naked eye as well as by the aid of the microscope. I have found that it is not uncommon, if a vein is cut open, spread out flat, and then held up to a strong light, for the walls to vary much in thickness at different parts, and in some places to be exceedingly thin. In the case of J. K——, sections were made transversely across a large branch of the renal vein, and the walls were found to be so thin that it seemed astonishing how it could have been at all an adequate container of blood.

In regard to the structural condition of the capillaries, for reasons already mentioned I do not even pretend to an opinion.

It may perhaps now be permissible to attempt to draw some contrast of the general features of the two cases from which my illustrations were taken. That of J. K—— was made the subject of a short paper read before the Philadelphia Pathological Society in the early part of 1888, and published in the "American Journal of the Medical Sciences" for June of the same year, and it will therefore not be well to do more than sketch the outlines of the case again. It was one of typical aortic regurgitation in a man fifty-four years of age. The heart disease came on late in life and without the occurrence of any attack of rheumatism more than some vague joint pains, which never confined him to bed, and he died gradually of heart failure, without dropsy or anything to point to involvement of the kidneys, except that when he first came under notice there was a trace of albumen in the urine, without casts, which, however, soon disappeared never to return. After death there were found brown atrophy of the heart, fibroid degeneration, thickening of the endocardium and of the aortic valves, and in both of these the existence of the peculiar cell-growth which has been described. The arteries and veins of the heart presented appearances already mentioned (Figs. 11 and 12). The lungs gave evidence of some catarrhal inflammation and their arteries of thickening of the intima. The liver-cells were much degenerated, and the arteries as in the other organs. The kidneys exhibited evidence of parenchymatous disease, there were casts in the tubules, and the arteries showed the same change as found in vessels elsewhere (Figs. 9 and 10). The condition of the renal artery and vein, and of the abdominal aorta, vena cava, and a small branch of the cava have already been mentioned. There were large inflammatory bands in one of the iliac veins, causing obstruction in that vessel.

The case of J. C—— presented in many respects a contrast. He was fifty-one years of age, and had suffered with some shortness of breath and palpitation for three years. When admitted to the hospital, about two months before his death, there was great dyspnœa, amounting to orthopnœa, and of this he never got rid. Dropsy and difficulty of breathing increased, and his sufferings became worse and worse; nothing seeming to afford him any relief until, finally, he died, having suffered what was almost agony. The conditions were in all respects those usually regarded as typical of Bright's disease, except that no casts were found in the urine, though albumen was always present. Post-mortem examination showed that the heart and all its openings were much enlarged, there was extensive brown atrophy of the muscular substance and calcareous deposit in the base of the aorta and valve-flaps. The minute veins exhibited irregular thickening of the intima, and the condition of one of the arterial branches is shown in Fig. 5. The pleura was thickened and the lungs adherent; there was emphysema and some catarrhal infiltration, and the condition of a minute arteriole is represented in Fig. 3. The liver was in a state of fatty and granular degeneration, and the hepatic arteries and portal veins were much thickened and diseased. There had been inflammation around the spleen, binding it to the surrounding organs, and on section it showed marked fibrosis, and the arteries were much thickened, the intima markedly so. There was parenchymatous disease of the kidneys, the capsules were thickened, and there were infarctions, and the arteries diseased (Fig. 4). The radial artery and femoral artery and vein were atheromatous and calcified (Figs. 6, 7, and 8). The abdominal aorta presented distinct irregular thickening of its intima. In the spinal cord there seemed to be some degeneration of the nerve-fibres, particularly of the peripheral nerves, and the arterioles presented the characters described and figured by Gull and Sutton ("London Path. Soc. Trans.," *loc. cit.*) as hyaline-fibroid degeneration. The walls were composed of a material which under the microscope appeared structureless, except that a few nuclei lay at the inner edge. In the medulla oblongata, as already mentioned, the right olivary body and its contained nucleus dentatus was much larger than the left. The large artery running along the front and that upon the posterior surface both presented in marked degree the irregular thickening of the intima. Figs. 1 and 2 show the condition of the intima of one of the middle cerebral arteries. Sections of this vessel higher up, or rather of its branches after it had divided into three, exhibited irregularly thickened intima in two of them, while the third presented an appearance quite natural.

In these two cases the mode of death and the picture presented by the history of the last few years of life were as dissimilar as could well be, though in many respects the pathological lesions found were singularly parallel. Though in the first case the man died what would commonly be considered a typical heart death, and in the second an equally typical kidney death, and there should have been, reasoning from analogy, a great difference in the pathological lesions, such was not the case. It would be difficult, if not impossible, for anyone, from a study of the pathological lesions alone in these two cases, to say that the modes of death would have been in anywise different. The most important of these lesions, perhaps, were the changes in the heart and kidneys, and in respect of these the two cases were not materially unlike, and in both were found besides extensive changes in the arterial and venous systems, which, though presenting many points of difference, were yet only varying features of what seems to be primarily the same disease.

The disease seems to be very wide-spread in its early effects even, and may first reveal itself clinically by a cough if it takes possession first of the lungs, or by the symptoms of apoplexy, if the brain arteries are the earliest to suffer injury, or by epistaxis perhaps, which has always seemed to me to betoken just as positively a physical change of the arterioles of the nares, though of this there is no pathological evidence as yet, as does the apoplexy show that the brain-arteries are diseased. Often have I found, by the most careful inquiry into the clinical history in cases of typical Bright's disease, that the first symptom with which the patient has suffered has been cough, and it is a fact well known how often persons dying of apoplexy are found to have had Bright's disease, and it is equally well known how often epistaxis is the first warning given of the existence of kidney trouble. There is, however, no reason, except that Bright first drew attention to the existence of changes in the kidneys (and this is no reason at all), to suppose that the diversified lesions were all caused by the changes in either the secreting substance or in the arteries of the kidneys.

The fact that cerebral hemorrhage and epistaxis are such common accompaniments or symptoms of chronic Bright's disease seems to me the strongest proof that it should not properly be considered to be one of the kidney, for there exists at the present time no evidence to show that the kidney disease which sometimes, but not always, exists in such cases, originated before the blood-vessel change which was their direct cause, nor is there even a very plausible theory to strengthen such a hypothesis.

In conclusion, it may be stated that my desire has been to make clear, by language and pictures, the view that in the so-called chronic Bright's disease, we have to deal with one which is wide-spread in its effects; that the most characteristic and probably most important changes, so far as at present known, are those of the intima of the arteries, in which probably the veins always participate; that changes in the muscular coat and adventitia, though often present, are by no means so important in their effects, and probably are secondary to those of the intima; that the process seems to be coextensive with, and probably is a part of, the change in the large arteries which is so common and so well known as atheroma; and finally, that it seems likely, in the absence of proof that changes in the nerve-substance are a necessary accompaniment, or even if such were proved to be the case, the lack of knowledge that they antedated the disease of the blood-vessels, that the earliest of the now known pathological lesions to make its appearance is the change in the intima of the blood-vessels.

My paper must not be closed without an acknowledgment of my great indebtedness to Dr. B. A. Randall for the beautiful illustrations I have been enabled, through his skill, to present.

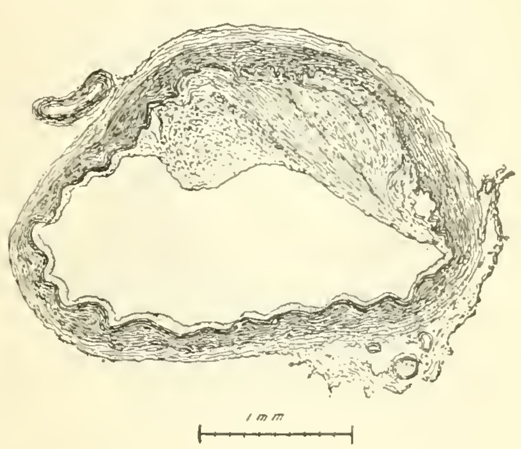

FIG. 1.—Case of J. C——. Middle cerebral artery, showing irregular outgrowth of intima. The accompanying vessels are somewhat enlarged; the adventitia and muscular coats are normal. The plicated membrane shows very distinctly around the entire circle. The intima is seen within the plicated membrane, and is thickened in the entire circuit: but at one side, and occupying about one-third of the circumference, the thickness is very great. At one portion of this mass there are numerous blood-corpuscles, entangled in the tissue, while at another there is distinct cellular structure. × 20 diameters.

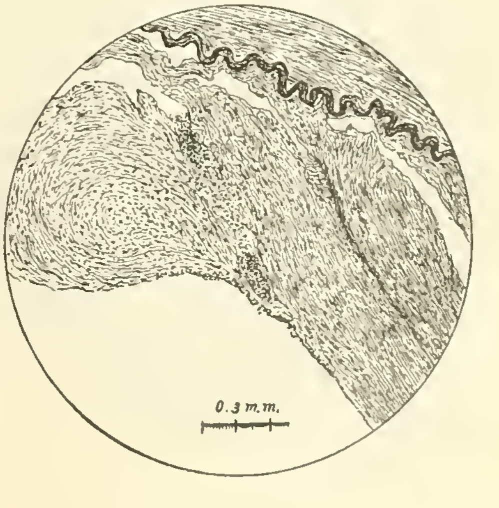

FIG. 2.—A portion of the same artery as Fig. 1, and showing the cell-growth and entangled blood-corpuscles, and that the general character of the structure of the most thickened portion of the intima is a fibrous material. The open spaces are probably due to tearing of the tissue in mounting. × 35 diameters.

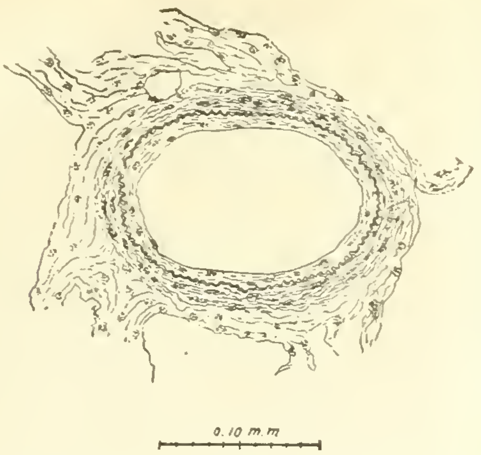

FIG. 3.—Case of J. C——. Minute arteriole from lung, showing great thickening of the intima, which contains a few scattered cells, though most of it consists of a homogeneous, structureless-looking material, quite different from the appearances seen in Figs. 1 and 2. The muscular coat and adventitia cannot be very satisfactorily differentiated, but they do not appear to be at all thickened. The plicated membrane is a marked feature of the picture. × 220 diameters.

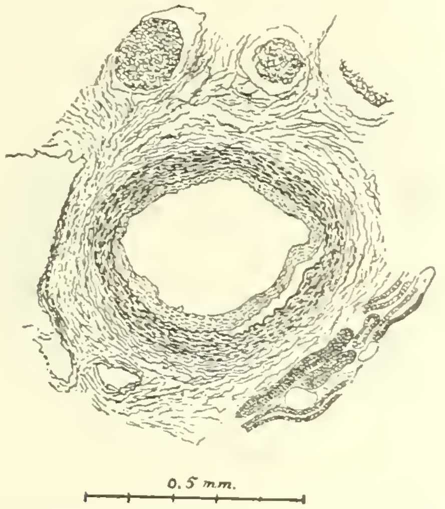

FIG. 4.—Case of J. C——. Minute arteriole from the kidney, showing great thickening of the intima, which is almost structureless, containing only a few scattered cells; there being in addition merely a few fibres running around the circle of the vessel. × 60 diameters.

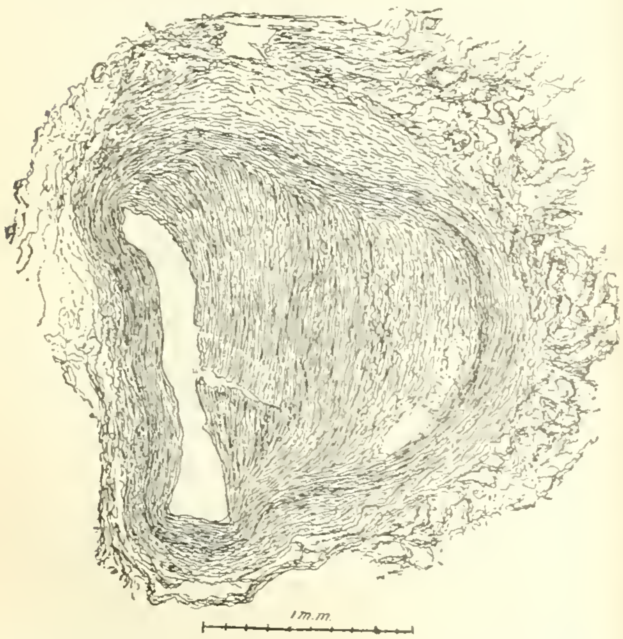

FIG. 5.—Case of J. C——. Branch of coronary artery from anterior surface of heart, showing almost the entire lumen of the vessel filled with an outgrowth, the opening being a mere chink. When seen with the amplifying power used in making the picture, this morbid material has, as represented, merely a fibrous appearance; more magnified, the deposit is seen to contain a great many cells and to be a well-organized fibrous growth. × 28 diameters.

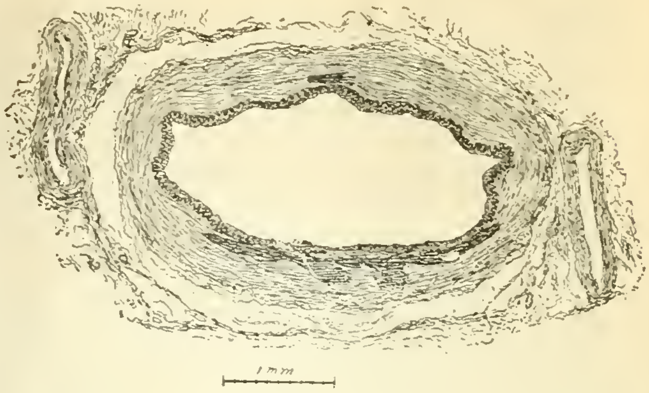

FIG. 6.—Case of J. C——. Radial with two accompanying arteries. It was so much hardened by mineral deposit that it had to be decalcified before sections could be cut. The differentiation of fibrous and muscular coats does not show well, perhaps owing to the soaking in acid to remove the salts, but more likely to the extensive atheromatous degeneration. The plicated membrane is a marked feature around the entire circuit, and the intima within it is much thickened. The atheromatous degeneration has extended deeply into the muscular layer. × 15 diameters.

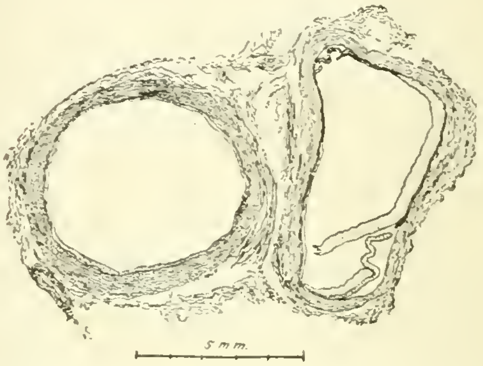

FIG. 7.—Case of J. C——. Femoral artery and vein. Both vessels were converted into rigid bony tubes by calcareous deposit and had to be treated with acid for its removal before sections could be cut. The artery shows ordinary atheromatous changes, the intima being irregularly thickened and spots of degeneration existing in the muscular coat. The vein shows an intima very greatly and irregularly thickened. At one place this coat and the muscular layer are broken loose from the adventitia. This probably occurred in removing the vessels from the thigh, for they were so rigid and firmly fixed in their position that some violence was necessarily used in cutting and tearing them loose. × 5 diameters.

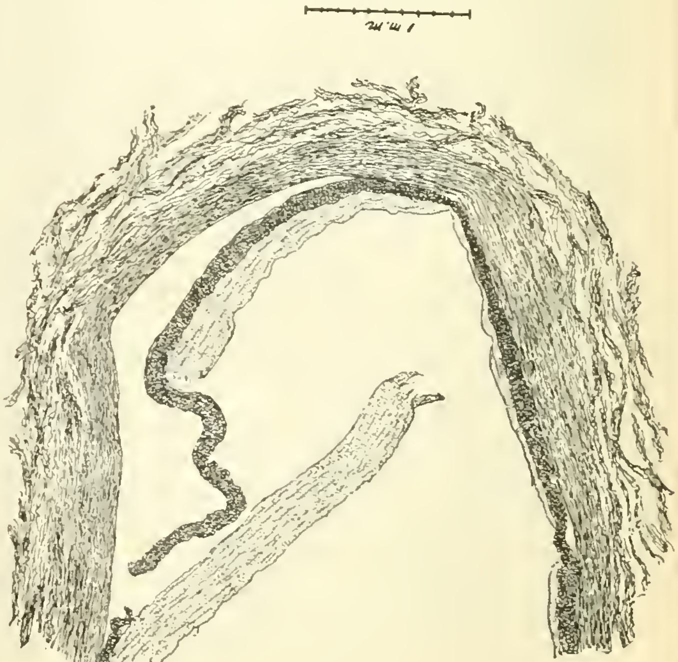

FIG. 8.—One-half of same vein as in Fig. 7, more highly magnified, and therefore better exhibiting the minute structure. × 22 diameters.

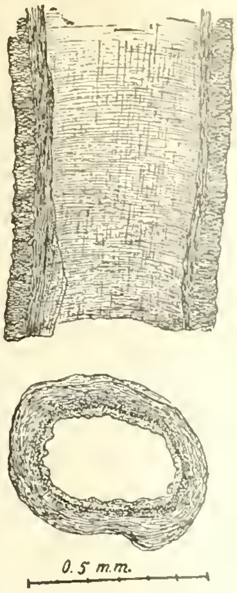

FIG. 9.—Case of J. K——. Views in longitudinal and transverse section of an artery from the kidney, which was removed under a dissecting microscope, and then split in half with scissors lengthwise, and mounted with the inner side upward in imitation of Dr. Johnson's pictures ("Medical Lectures and Essays," by George Johnson, 1887). There are visible the inner surface of the artery and the edge of the intima and muscular coats. The fibrous coat does not show at all, and this is the case in Johnson's figures also. The intima is thickened, and in various degrees at different areas; this might be said to be due to irregular cutting of the vessel, but is disproved by what is seen in the transverse section. The circular view is of the same vessel, but cut transversely with a pair of scissors. This shows marked thickening of the intima and its irregular distribution, and the plicated membrane is a marked feature of the picture, though not visible at all in the longitudinal section. The question whether the muscular layer was thickened in this vessel is one which might well be disputed, though there can be no doubt of the thickening of the intima and its difference in degree at different positions. × 68 diameters.

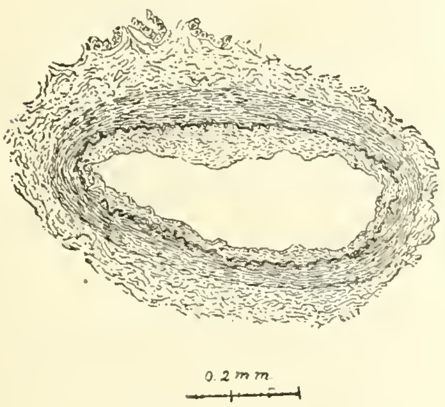

FIG. 10.—Case of J. K——. Minute arteriole from the kidney, showing marked irregular increased thickness of the intima. × 100 diameters.

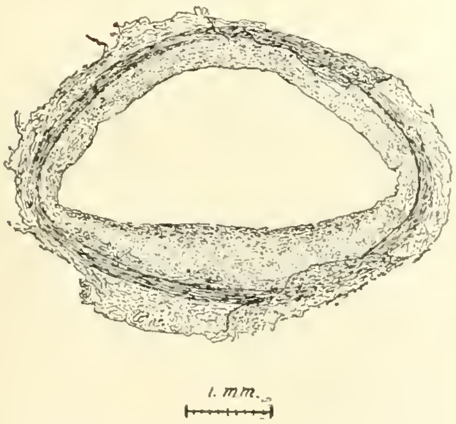

FIG. 11.—Case of J. K——. Third descending branch of left coronary artery (runs down front of heart in or near interventricular septum), exhibiting, most beautifully, extensive atheromatous degeneration. In two positions there is slight imperfection in the mounting, the outer portions of the section being folded over. There was no calcareous matter deposited in this vessel. The fibrous and muscular coats exhibit no extensive changes, there being merely slight invasion of the latter by the degenerative processes, and this is visible in the lower portions of the figure. The plicated membrane has been destroyed everywhere except in the portion of the artery figured at the right-hand side of the picture, and there it forms a marked boundary between the muscular coat and intima, which latter, throughout its entire area, is most markedly and irregularly thickened. In the lower part of the picture, at the junction of the intima and muscular coats, atheromatous degeneration and softening is shown to have taken place, and extended into both the layers. The state of the intima of this vessel is typically characteristic of the diseased condition which it has been desired to describe and represent. × 12 diameters.

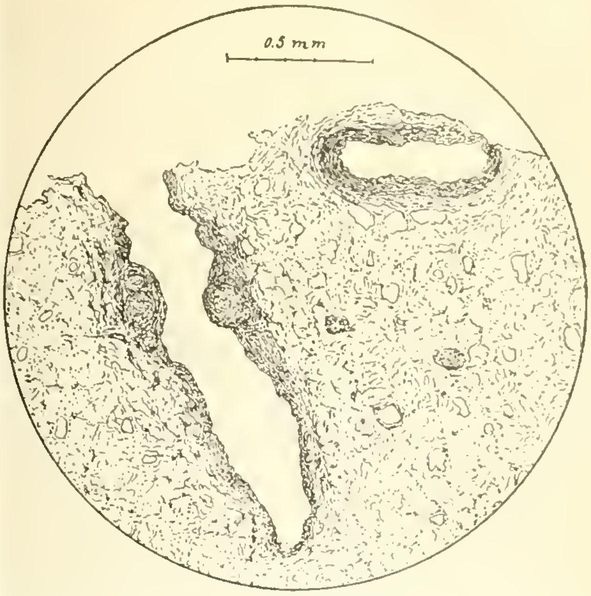

FIG. 12.—Case of J. K——. Of a vein and artery, contained in the adipose tissue, from the anterior surface of the heart, near the interventricular septum. The walls of the vein are generally thin and of loose texture, but there are two masses lying in the intima upon opposite sides of the vessel which are made up of tissue which evidently has a cell-like arrangement. More magnified, this is plainly seen to be composed of cells arranged in nests, and is precisely similar in structure to what is found in the intima of arteries, and in the endocardium and heart-valves. × 40 diameters.

NOTE.—These are from pen-drawings by Dr. B. A. Randall, and the plates were made by photographic process, and reduced from the original size by about one-quarter to one-half.

REMARKS ON EXERCISE WITHOUT FATIGUE IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

By JOHN RIDLON, A.M., M.D.,

ATTENDING ORTHOPEDIC SURGEON TO ST. LUKE'S HOSPITAL; ATTENDING SURGEON TO THE FIRST ORTHOPEDIC DIVISION, DEPARTMENT FOR THE OUT-DOOR POOR, BELLEVUE HOSPITAL; LATE INSTRUCTOR IN ORTHOPEDIC SURGERY, MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK; LATE SENIOR ASSISTANT AND OUT-DOOR VISITING SURGEON OF THE NEW YORK ORTHOPEDIC DISPENSARY AND HOSPITAL.

I THINK no one will deny that increased lung capacity, increased strength of the respiratory muscles, and increased general nutrition are greatly to be desired in patients suffering with pulmonary tuberculosis. Of the three, perhaps the last mentioned is most important, inasmuch as in very many cases the other two are impossible without it. The various methods of administering oxygen and compressed air that have been tried during the past few years seem to have for their aim and end chiefly the increasing of the lung capacity. Now, increased lung capacity without proportionate increase of power in the respiratory muscles is of no use; and increased lung capacity *with* increased power (which implies increased bulk) of the respiratory muscles, but *without* proportionate increase of the general nutrition, is simply a burden to be soon put aside. Increased general nutrition without increased lung capacity, and increased power of the respiratory muscles, is what we have aimed for, and in some measure gained, by proper attention to medication, diet, bathing, and life in the open air. That the gain is too often but temporary does not need to be said. The importance of the diet has come to be understood, and most physicians are quite as competent to prescribe the proper food as the proper medicine. Patients are no longer told, "You must feed up," any more than they are told, "You must take some medicine for that cough."

With the all-important subject of exercise, however, it is different, and patients are still told, "You had better use dumb-bells," or, "You had better swing clubs," and are left not only without instructions as to the weight of the bells or clubs to be chosen, but also in ignorance of the exercises most to be desired in their particular cases, and the length of time to be employed in each and in all of the exercises. It would be quite as safe to say to a patient: "Get some belladonna and take it for your night-sweats," for the use, or attempted use, of bells and clubs weighing from twelve to twenty-five pounds is not only inadvisable, but may be positively harmful. If bells are to be used at all, they should be from two to five pounds, and clubs from two and one-half to three and one-half pounds; I would not, however, recommend the use of either. The development of great muscular masses in a few locations is not desirable; rather let it be strength and suppleness of small muscular masses over the whole individual, and the increased vigor which that implies. Mountain-climbing is an exercise that has much to recommend it, and should be part of the treatment of every patient who has the strength to climb and the money to fully care for himself in the mountains. Unfortunately, in our latitude, mountain-climbing is limited to four, or at most five, months of the year, and many lose, during the remaining months, all or more than has been gained. Even during the summer months something is lost by rainy days, and something risked by unavoidable exposure; and many patients are not to be trusted to prescribe for themselves the proper dose of mountain-climbing. All things considered, the vast majority of phthisical patients must depend upon something else for their salvation; and this brings us to the consideration of the questions implied in the title of this paper. If the lung capacity can be increased from ten to thirty per cent., and the strength of the respiratory muscles proportionately, and the general nutrition and bodily strength be brought up to a par with these by exercises without fatigue, it would seem that such a course of treatment would be worthy of our earnest consideration.

My experience in the treatment of weak and nervous children, and patients having scoliosis, convinces me that this *can* be done. I beg leave, then, to suggest the following exercises, to be given daily, for from three to six months, in a large, sunny, well-ventilated room, *by the physician himself*, who must regulate, according to the condition of his patient, the duration of each exercise and the rests between, and must see to it that they are not carried to the point of fatigue. When the patient has gained sufficient strength to make exercise with resistance desirable, the physician must himself give that resistance, and no more delegate it to a nurse or a servant than he would the treatment of a hernia or a case of spinal curvature. When it is possible, it is a convenience to have a special table for the patient to rest upon; one about 34 inches high by 72 inches long and 12 inches broad will be found useful. This should be only moderately well-padded, and the head should *not* be supported upon a pillow. All clothing should be loose.

1st *Exercise.*—Lying, shoulder tips well down, hands supine with little fingers close to legs, breathe deeply, in through the mouth and out through the nose.

2d *Exercise.*—Lying, hands stretched outward at right angles to the body, and backward as far as possible; breathe as in first exercise.

3d *Exercise.*—Lying, hands stretched upward, arms parallel at the sides of the head; breathe as above.

4th *Exercise.*—In first position, flex and extend the toes, flex and extend the feet, abduct and adduct the feet.

5th *Exercise.*—Flex the legs on the thighs and the thighs on the pelvis, and extend the same.

6th *Exercise.*—Circumduct the legs, with the knees, ankles, and toes extended and held rigid.

7th *Exercise.*—In the second position, flex and extend the fingers, separate and bring together the same; flex and extend the hands, abduct and adduct the hands.

8th *Exercise.*—In the third position, flex the forearms on the arms and the arms on the trunk (bringing the elbows down at the sides and the palms forward); extend the same.

9th *Exercise.*—In the first position, circumduct the arms, upward (being parallel), backward, outward and downward to the first position, the elbows, wrists, and fingers being extended and rigid.

10th *Exercise.*—In the second position, rotate the head, twisting the neck on the long axis of the body.

11th *Exercise.*—In the third position, grasp a stick with the hands about eight inches apart, and carry it forward and downward to the thighs, then upward.

12th *Exercise.*—Backward bending while the physician lifts the head with locked hands.

13th *Exercise.*—Patient lying prone, circumduct the legs, outward, upward, inward and downward.

14th *Exercise.*—Same position, the legs being held down by the physician, the patient slowly raises the head and shoulders from the table; the hands may rest on the hips, or at the back of the head, or be stretched upward, according to the strength of the patient.

When sufficient strength has been gained No. 12 may be taken with the head and shoulders extending beyond the end of the table. Also let the patient, while lying on his back, flex the legs over the end of the table, and while they are held in that position by the physician, or locked around the legs of the table, flex the trunk on the thighs to the sitting position and then slowly let himself down again to the lying position. When the patient is still stronger he may lie prone, with the body above the hips extending beyond the end of the table, and, the legs being held down, he flexes the body downward, and raises it as high as possible, with the hands as in No. 14.

That these exercises should not all be given at once and in the order laid down would seem to be self-evident. The following is appended as a good prescription to commence with:

Number 1,	five times.	Number 9,	two times.
Number 4,	three times.	Number 1,	three times.
Number 2,	five times.	Number 5,	two times for each leg.
Number 7,	three times.		
Number 3,	five times.	Number 8,	two times.

Then let the patient rest for some time in the second and third positions. Ordinarily the rests are made in the first position. Care should be taken that each exercise be done vigorously but slowly. Let there be no throwing about of the arms and no shiftlessness. One movement properly executed is of more value than all carelessly performed.

337 West Fifty-seventh Street.

THE RECURRENT MACULAR SYPHILIDE.

By S. TYNBERG, A.B., M.D.,

LATE HOUSE SURGEON, CHARITY AND MATERNITY HOSPITALS, NEW YORK.

In the issue of The Medical Record for May 12, 1888, there appears an article by Dr. T. H. Rockwell, under the title "A Case of Recurrent Macular Syphilide," giving a detailed history of the same and accompanying it with the assertion of its extreme rarity.

The perusal of the article alluded to will undoubtedly impress the average busy practitioner that his observations of the manifestations of syphilis have been unrewarded by a similar case. The desire to dissipate this false impression, and the hope of encouraging a closer study of cases which deviate from the regular course, have prompted me to write these few lines.

There is no doubt that conclusions based upon false premises have primarily been the cause of the impression that any irregularity in the manifestations of syphilis are exceedingly rare and should be considered exceptional.

It is admitted by some of the highest authorities that if proper specific treatment be initiated upon the appearance of the chancre, the secondary, and certainly the tertiary lesions and symptoms may be averted.

On account of the great difficulty and liability to err in diagnosing the initial lesion, treatment, excepting local, is suspended until the appearance of positive lesions of syphilis, generally the roseola (macular syphilide). Specific treatment is now instituted, and, if energetically continued, all the other lesions of syphilis will in a great many cases be averted, the roseola also fading, leaving but the evidences of an eruption, the well-known ham-colored spots. If treatment be interrupted, the disease will, as a rule, continue its course, the papular syphilide and subsequent symptoms appearing in their order, or in some cases there will be a recurrence of the macular syphilide which will disappear on resuming treatment, or be followed by the subsequent lesions and symptoms if treatment be not again instituted.

Various conditions and circumstances will often modify the course of the disease. I have not infrequently seen, especially in hospital patients, who, as a rule, have not paid the greatest regard to hygienic or dietetic principles, an erythema appear after a debauch, after indulgence in certain articles of food, and especially after the ingestion of various medicaments. This resulting erythema is almost universally attributed to one of the various causes mentioned, the possibility of its being a recurrence of the roseola is, on account of popular impression, totally disregarded. It is the old fallacy of *post hoc ergo proctor hoc.*

That the causes alluded to will produce an erythema similar to the macular syphilide no one will deny; but that the erythema is often a recurrent macular syphilide, the supposed exciting agents being merely a coincidence, and bearing no influence whatever in the production of the subsequent erythema, should also be admitted.

Let it be borne in mind that during the prevalence of any of the above-mentioned causes, treatment proper is generally inhibited, it is consequently this inhibition of specific treatment directly, and the exciting causes indirectly, which allow the disease to continue its career. Errors in diet and disregard of the principles of hygiene, though treatment be continued, may so affect the tissues that the body is unable to resist the progress of the syphilitic virus, and in this way there often recurs a macular syphilide.

There are a great many other circumstances which may cause the symptoms to deviate from their regular course.

I have before me the histories of a few hospital patients which almost coincide with the case published in THE RECORD.

In order not to occupy too much space I will merely give a brief history of two cases, at present under my care in private practice.

CASE I.—Mr. C. F——, aged forty-five; married; German; merchant. Was the recipient of a chancre sixteen months ago. Treatment was not instituted until the appearance of definite symptoms, which came in about three weeks.

At this time there appeared a very slight roseola about the flanks, mucous patches in the mouth, especially the posterior part, induration of the cervical and inguinal lymphatic glands, and a marked rheumatic tendency. Having had malarial trouble before, I put him upon pills composed of massa hydrargyri and quiniæ sulphas, āā gr. ijss., t.i.d. The disease was checked under this treatment, all active symptoms disappearing and the patient making good progress.

At the end of five months. business necessitated his temporary absence from the city, during which time he neglected treatment, and upon his return, after a sojourn of six weeks, he applied for treatment for his throat. On examination it was found to be the seat of mucous patches; in other words, a recurrent macular syphilide on the mucous membranes, no other local evidences of the disease being present, and no symptoms, with the exception of slight rheumatic pains.

Cauterization of these patches and renewal of the treatment caused the disappearance of these symptoms.

Patient is now on the bichloride pill, gr. $\frac{1}{20}$, t.i.d., and any temporary discontinuance of treatment always results in the appearance of mucous patches unaccompanied by any other local manifestations of the disease.

CASE II.—Mr. V. H. K——, aged twenty-three; United States; single; traveller. A chancre appeared on the dorsum of the penis in December, 1886, which was cauterized and further treated by a druggist until he came under my care in January, 1887, complaining of a "sore throat."

His forehead was the seat of a well-marked erythema, presenting a splendid example of the "corona veneris."

On stripping the patient, I discovered that his back, thorax, part of the abdomen, and upper extremities presented a diffuse macular eruption, which the patient attributed to some blood-medicine the druggist had given him "to purify the blood and drive out the poisonous matter." Mucous patches were found upon the tonsils, tongue, and posterior wall of the pharynx; there was enlargement of the epitrochlear, inguinal, post-cervical, and submental glands, the latter being the seat of great tenderness. He complained of slight alopecia and rheumatic pains. The initial lesion itself was healed, presenting an exaggerated induration, probably due to the continued cauterization it had been subjected to. Otherwise the patient presented a healthy appearance. I immediately cauterized the mucous patches with sol. argenti nitratis, gr. xl. : ℥ j., and put him on the pil. protoiodide, gr. $\frac{1}{4}$, t.i.d., with syr. ferri iodi. as a tonic. He soon showed signs of improvement, the mucous patches subsiding in a few days, and the eruption and other symptoms gradually disappearing.

After a short time the patient was free from all visible signs of the disease. At the end of four months patient was compelled to resume his occupation, and consequently left the city for a long trip. He continued the same treatment for two months, during which time he remained well, when, without consulting me, he discontinued his pills.

A few days thereafter—that is, about six months from the first appearance of the macular syphilide—his face became the seat of an erythematous syphilide, similar to the one which previously existed, while now the body remained perfectly free and no other sign of the disease was present, except mucous patches in the mouth. He immediately came to the city when I observed what has just been narrated.

The old treatment was resumed, whereupon the symptoms gradually disappeared. This improvement continued until the end of the year, when, after a dissipation of three or four days, the same phenomena again recurred, only to disappear after being put upon the mixed treatment. Since then patient has been well, and shows no sign of the disease except inguinal glandular enlargement.

These are two cases which will come under the category of the title of this paper. There is no doubt that, as attention has been called to these cases, we will now hear of a great many which before were not at all considered peculiar.

That cases of recurrent macular syphilide are not very frequent, I will admit; but they do not occur so rarely as to be classed among the exceptions.

A more careful observation of syphilitic patients will undoubtedly develop a comparatively large number of these hitherto exceptional cases.

321 EAST FORTY-SECOND STREET.

ACETOPHENIDINE.—M. Guerorguiewsky has employed acetophenidine instead of antipyrine. It is a crystalline gray powder, insipid and inodorous, derived from phenol; it is soluble only in twenty parts of alcohol, and is eliminated by the urine, wherein it can be detected by the red coloration with perchloride of iron. In typhoid fever, tuerculosis, erysipelas, and pneumonia, in doses of from fifteen to thirty centigrammes, he found it to act as an antipyretic in from twenty to forty minutes after injection, the pulse and respiration diminishing in frequency, and sweating being induced. It also relieved pain, but doses of fifty or sixty centigrammes are required to effect this end, as in migraine, cephalalgia, and tabetic pains. It never upset the stomach, or modified any of the other functions of the body; in this respect it claims to be superior to antipyrine.—*The Lancet.*

INCIDENCE OF SCARLET FEVER IN RELATION TO EPIDEMIC OF SORE THROAT AT BETHERSDEN, ENGLAND, IN 1884, PRODUCED BY EXPOSURE TO MANURE DERIVED FROM CATTLE AFFLICTED WITH APHTHOUS FEVER.

By J. W. STICKLER, M.D.,

ORANGE, N. J.

No. of cases.	Age.	Scarlet fever previously.	Scarlet fever since.	Remarks.
1	8	0	0	Members of same family.
2	10	0	0	
3	18	0	0	
4	6	0	0	Members of same family. Four other members of this family, who had previously had scarlet fever, escaped epidemic of sore throat.
5	8	0	0	
6	5	0	0	Same family, cases 7 and 8, mild sore throat, probably modified by previous scarlet fever.
7	7	1	0	
8	9	1	0	
9	3	0	1	Very slight case of scarlet fever last year.
10	8	0	0	Same family.
11	2	0	0	
12	1	0	0	
13	9	1	0	Same family. No. 15, mild case of scarlet fever. No doctor employed.
14	7	0	0	
15	11	0	0	
16	9	1	0	Same family. No. 18, mild case of scarlet fever.
17	2	0	0	
18	12	0	0	Same family. Three other members of this family, who had previously had scarlet fever, escaped throat epidemic.
19	5	0	0	
20	4	0	0	
21	2	0	0	Same family. Case 24, throat case mild.
22	22	1	0	
23	6	0	0	
24	7	0	0	
25	7	1	0	
26	8	0	0	
27	6	0	0	
28	9	1	0	Scarlet fever? said to have been mild. No doctor.
29	9	1	0	Sore throat case, mild one.

The above facts were collected by Dr. M. K. Robinson, of Dover, England, at my request. Taken in connection with the statistics published in The Medical Record, December 10, 1887, they appear to strengthen the theory that a person who has had an attack of scarlet fever is rendered either wholly or partially insusceptible to the contagium of foot-and-mouth disease, and *vice versa.* Professor Law, of Cornell University, in discussing my first paper upon this subject, said: "Epizootic foot-and-mouth disease had at times attacked nearly all the cattle and people (of Europe), and, considering the fact that the disease was so frequently prevalent, there should be less scarlet fever in Great Britain than in America, where the foot-and-mouth disease was comparatively unknown." Professor Walley, of Edinburgh, says *very few people contract foot-and-mouth disease.* There is, therefore, a very manifest difference of opinion between these two gentlemen upon this point, and while the opinion of both should be carefully considered, it is quite evident that only one can be correct.

I have consulted considerable literature bearing upon this matter, and find comparatively few cases recorded. So far as the animals of Europe are concerned, it may be said the disease (eczema epizootica) is a very common one, occurring frequently among them as an epidemic. Another point, urged by L. McLean, is that one attack in the bovine species does not give immunity from the disease; but in the ovine species it does. Is not this fact suggestive? May it not be true that man may be protected by a single attack of the disease, as is true of sheep? It is undeniably true that natural physical conditions have much to do with the production or recurrence of any disease.

Swallowed a Pin.—An anxious patient who thought that he had swallowed a pin, telegraphed for advice to a well-known physician of Easton, and received in reply the reassuring injunction to "swallow a pin-cushion."

THE TREATMENT OF UTERINE FIBROIDS BY THE APOSTOLI METHOD.[1]

By A. B. CARPENTER, M.D.,

CLEVELAND, O.

The treatment of uterine fibroids by the Apostoli plan or method has come forward so prominently of late, and the claims for the success of this plan are so positive, that I desire to call attention to what is being done in this direction to ameliorate the sufferings of this class of cases without resort to the knife, and at the same time offer a few suggestions based upon practical observations.

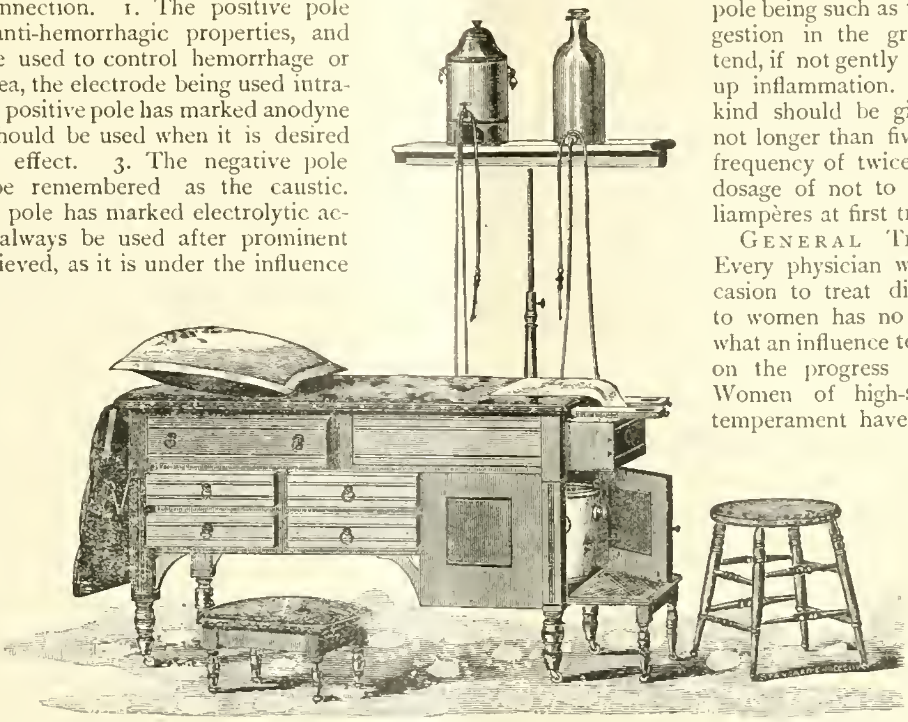
In 1885 Mr. Moore Madden, of the Rotunda Hospital, Dublin, read a paper before the British Gynecological Society of London, wherein he stated as his opinion, that if we could carry these fibroid cases on to the menopause, in a great majority of instances the troublesome symptoms will disappear, and a permanent relief be afforded; that during the menstrual life the tumor annoys, but, as a rule, does not kill, and that with cessation of ovarian activity the growth gradually reduces in size, the aches and sufferings pass away, and life again becomes worth living. He showed by statistics, which I take the liberty to quote, that the mortality arising from the operation for hysterectomy is from twenty-five to thirty-five per cent., in the hands of the best operators. He says: "Mr. Lawson Tait published in the same year (1885) an account of fifty-four hysterectomies, with nineteen deaths; Dr. Keith thirty-eight cases, with three deaths; while Dr. Bigelow collected from all available sources three hundred and fifty-nine cases, with one hundred and thirty-two deaths." At this time Mr. Lawson Tait was in the height of his glory, and was performing the operations for oöphorectomy and hysterectomy upon nearly every patient that came under his care afflicted with uterine myoma. The paper attracted a great deal of attention and discussion, and very emphatic opposition from Mr. Tait, as Mr. Madden declared that the mortality under the non-operative plan of management was so low as to be hardly worth recording. The paper can be found in the "Transactions of the British Gynecological Society," vol. i., page 139, and is well worth reading, as it marks the beginning of protest on the part of the conservative element in the profession against the indiscriminate use of the knife in the treatment of these cases. At about this time Apostoli began to advocate more strongly his method. It may be claimed that electrical treatment for the cure of uterine fibroids was in use, and by men in this country, long before Apostoli was known; this is granted, but how was it used? By some the continuous or galvanic current was applied, by others the faradic, and through the medium of machines that were as but mere toys in accomplishing electrolytic action; with little or no knowledge as to the therapeutics of the current, no positive or even well-defined idea of what they wished to accomplish, and an absolute ignorance of the strength of the current administered. The treatment was purely empirical, wholly unscientific, applied with the vague hope that by a certain something, they knew not what, beneficial results to the patient were to be obtained. Quacks and charlatans imposed upon an always credulous public with their toy batteries and claptrap apparatus, and it is not to be wondered that the subject of electricity became almost as a stench in the nostrils of the better class of practitioners.

To Apostoli is due in a great measure the credit of having come forward and lifted the subject from the quagmire and domain of quackery, and placed it before the profession on a plausible basis and in a scientific light: Plausible, because we can see our way to the establishment of electro-therapeutics prescribed on the basis of exact dosage. Scientific, because, by understanding the physiological action of the positive and negative poles, we are enabled to intelligently use them, and with a reasonable assurance of success.

What are the claims of Dr. Apostoli regarding the treatment of uterine fibroids by the electrolytic method?

I will quote him. 1. Hemorrhage is controlled. 2. The troubles of menstruation, dysmenorrhœa, and nervous disturbances are relieved. 3. The direct pains in the growth and pains arising from mechanical pressure are removed. 4. The harassing series of reflex pains, rectal and vesical, are destroyed. 5. The tumor is in a majority of instances made to entirely disappear. 6. The treatment is simple, anyone in possession of the required apparatus being able in a short time to administer it. 7. The mortality following this method is nil, providing the directions for operating be faithfully carried out. 8. Relief of symptoms in some cases must be accepted in lieu of cure.

Before going on to the consideration of important points in treatment, attention is called to the action of the positive and negative poles, familiar to many, yet pertinent in this connection. 1. The positive pole has styptic or anti-hemorrhagic properties, and should always be used to control hemorrhage or uterine leucorrhœa, the electrode being used intra-uterine. 2. The positive pole has marked anodyne properties, and should be used when it is desired to produce this effect. 3. The negative pole should always be remembered as the caustic. 4. The negative pole has marked electrolytic action, and should always be used after prominent symptoms are relieved, as it is under the influence of negative galvanism that the tumor is made to reduce in size.



Practical Observations.—1. Antiseptic precautions. 2. Evidence of pelvic inflammation. 3. Is the tumor very sensitive to pressure? 4. General temperament of the patient. 5. Electrical dosage. 6. Frequency of treatment. 7. Control of patient.

Antiseptic Precautions.—If antiseptic precautions are of any avail in the department of medicine or surgery, they should certainly be made use of here. Vaginal irrigation before and after treatment I believe imperative. For convenience in making this irrigation a table, devised by myself and here illustrated, will be found not only useful but very convenient; the working is readily understood by reference to the cut.

Sublimate 1-2,000 is used, and the vagina filled with dry antiseptic cotton for twelve hours.

Evidence of Pelvic Inflammation.—Should there be evidence of pelvic inflammation of acute or subacute form, great care must be observed in the beginning of the treatment; the electrode should be introduced with great care and gentleness, and a small number of milliampères of current given, otherwise we shall find ourselves with a case of cellulitis on hand, our patient discouraged, and worse than when she came. It is now my practice to give a few treatments by simply applying a sponge electrode through a glass speculum directly to the cervix, giving positive galvanism to the number of fifty or sixty milliampères. By this method a double purpose is accomplished. 1. The patient becomes accustomed to the current and to her new medical attendant, her fears become allayed, and she is in much better condition to endure the more heroic methods that are to follow. 2. Pelvic pains resulting from inflammatory disturbances, and the neuralgic, so called, are very much benefited by positive galvanism from a current of high tension applied as above described three times each week. It is my custom to give ten- to fifteen-minute sittings, of from forty to sixty milliampères, being governed by the patient's feelings; in no case, however, should a current be employed so strong as to produce an aching or burning pain in the pelvis.

After a fortnight an attempt is then made to introduce the platinum electrode into the uterine canal, and a small number of milliampères—five to ten—given. I gradually feel my way and increase the dosage according to the toleration of the patient.

Is the Tumor very Sensitive to Pressure?—If we find the tumor very sensitive to pressure upon examination, thus giving the patient considerable sharp pain, the duration and frequency of the treatment must be modified accordingly, the intervals between the sittings to begin with longer, and the dosage lighter, the action of the negative pole being such as to produce congestion in the growth, and thus tend, if not gently managed, to set up inflammation. Cases of this kind should be given sittings of not longer than five minutes, of a frequency of twice a week, and a dosage of not to exceed ten milliampères at first treatment.

General Temperament.—Every physician who has had occasion to treat diseases peculiar to women has no doubt noticed what an influence temperament has on the progress of these cases. Women of high-strung nervous temperament have to be handled with much gentleness, they have a horror of instruments, and their uteri bear the sound badly. In these cases galvanism must be proceeded with in a cautious manner, if we expect to gain the confidence of, and secure co-operation on the part of these patients.

Electrical Dosage.—*The system of electrical dosage, as advised by Apostoli, is, for the average American woman, in my opinion, too high.* This may appear as audacity on my part, but I wish to be distinctly understood as opposed to two hundred and fifty, or even two hundred milliampères, being confident that this enormous dosage is liable to do great harm, and also confident that equally good results will be obtained by a much smaller dosage.

It may require a little longer time to produce the desired results. The tumor may not shrink quite so rapidly, but the treatment will not cause nearly the pain, and the danger of complications of an inflammatory character are greatly lessened.

I believe that an apparatus capable of supplying a galvanic current of one hundred milliampères, *with the patient in the circuit*, is all that is required, and that the best possible results with this dosage can be obtained.

Frequency of Treatment.—As to frequency of treatment no positive rule can be given. The condition of the patient, her ability to tolerate, and the circumstances in a given case must be our guide. As a general rule, however, three sittings each week will be all that is required. This does not apply to profuse hemorrhages, which, if the case be urgent, may be treated daily. The sittings should be from five to fifteen minutes in duration, according to the dosage, a longer sitting for a smaller number of milliampères, in my opinion, accomplishing as good results.

Control of the Patient.—Although Apostoli claims that no special restrictions are necessary to be placed on the patients during a course of treatment, *it seems to me* *imperative that they should be on their feet as little as possible.* It is my experience that after a few weeks the cases improve, and as they improve they become correspondingly active, and unless they be held in check by a very firm hand, they are, before they are aware, going about and taking an amount of exercise that is certainly not conducive to rapid improvement; they return complaining of pain in the back, pelvis, and thighs, and upon inquiry admit of over-exercise to a degree that is sometimes extraordinary.

A rest of an hour in the office, providing an extra room is at our command, and of not less than half an hour, when the patient is receiving a high dosage, is imperative, together with absolute rest at home for a few hours following the treatment. This should be insisted on in every instance. These directions are entirely at variance with those of Apostoli, yet I cannot withhold calling attention to them and advise their observance in every case.

With the statistics quoted from Mr. Madden's paper before us, showing a mortality resulting from twenty-five to thirty-five per cent. in operations for hysterectomy, it seems to me that no man is justified in advising or performing this most terrible of all operations until he has given the patient a trial of the Apostoli method. Should electricity fail to give relief, we have not complicated matters; we shall always have laparotomy to fall back upon, providing our patient's condition becomes unbearable or hemorrhage threatens life, and with no less chance for recovery.

KING'S CLAMP IN THE TREATMENT OF VARICOCELE, WITH REPORT OF TWO CASES.

By C. H. RODI, M.D.,

RED JACKET, MICH.

In treating varicocele by excision of the scrotum, in which the scrotal clamp is used simply as a guide to the surgeon, there is always considerable hemorrhage after the clamp is removed, and great care must be taken to arrest all bleeding points before the scrotum is closed. Even after the utmost care, secondary hemorrhage often occurs, and it becomes necessary to reopen and secure the bleeding vessels. Generally there is suppuration, and the slow process of healing by granulation ensues. By the use of Dr. Ferdinand King's clamp, together with antiseptic precautions, all trouble, I think, can be avoided, and union by first intention obtained in nearly every case. By the use of this clamp there is absolutely no hemorrhage, and the operation is completed *before* the removal of the clamp, thus preventing the entrance of air or germs.

An illustration of the clamp is given in The Medical Record of November 13, 1886. It has a longitudinal groove to receive a fold of scrotum, which prevents slipping, and is perforated with small holes, about one-eighth of an inch apart, through which the sutures are passed, and it is so arranged that the clamp can be removed after the sutures are tied. A small Hagadorn needle, with fine catgut sutures is to be preferred. Union by first intention can be safely expected.

The two following cases, in which I assisted Dr. A. I. Lawbaugh, may be given as illustrations:

May 4, 1887, John D——, aged twenty-four, Osceola, Minn. Patient anæsthetized; parts washed with mercuric chloride solution, 1 to 1,000; King's clamp applied, and fixed by set screws; redundant scrotum excised. Fine carbolized catgut sutures were passed through the holes in the clamp, and tied, making interrupted sutures, one-eighth of an inch apart, the whole length of the incision. No hemorrhage followed the removal of the clamp. Union took place by first intention, without any unpleasant symptoms, and the patient was able to return to his work twelve days after the operation.

Case II.—James E——, Red Jacket, Mich., September 15, 1887. Anæsthetized; King's clamp applied. The redundant portion of scrotum was excised, and the wound was closed with fine catgut sutures. There was no hemorrhage. Union occurred by first intention, and the patient was out of bed and about the house on the second day. There was no swelling or inflammation at any time.

OXALATE OF CERIUM IN DYSMENORRHŒA.

By M. L. CHAMBERS, M.D.,

PORT JEFFERSON, L. I.

A number of years ago a young lady visiting in this locality applied to me for a remedy for the relief of dysmenorrhœa. She was of fine physique, in perfect health, and stated that she expected her "sickness" on the following day.

Looking into her ruddy face, I thought a little pain would do her less harm than a dose of morphine, the only thing I had at hand in which I had any confidence as a remedy; so I compromised with my professional conscience in order to please the expectation of my patient, and gave her, as I thought, a simple placebo, which should have the merit at least of being tasteless and harmless. This was oxalate of cerium, four powders of five grains each, one to be taken every hour until the pain should be relieved. To my surprise I received a note from the lady a short time after, asking for some more of those powders, and stating that three of them had given her entire relief. This was not sufficient to establish my belief in oxalate of cerium as a remedy for dysmenorrhœa, but I accepted the lady's statement as a hint for future experiment, and began giving the oxalate to all applicants for relief from this disorder. I soon learned that in certain forms of dysmenorrhœa it is as near a specific as the Materia Medica furnishes for any disease.

As dysmenorrhœa usually occurs in young unmarried women, I have seldom pursued my investigations for the purpose of diagnosis further than that of rational inquiry, and, in consequence, cannot state, except by symptoms, to which form of dysmenorrhœa the remedy is most applicable. It is in that kind, however, frequently occurring in fleshy and robust women with scanty discharge, in which the pain comes on before the flow, or at its commencement, is spasmodic or colicky, accompanied by a feeling of tenesmus, and is relieved when the flow is thoroughly established, that the remedy is most useful. I do not remember a failure when given in cases selected with reference to these symptoms. I give it in powders of six grains each, one to be taken every hour until the pain is relieved.

Sometimes the oxalate of cerium contains small quantities of arsenic as an impurity; in which case it will irritate a delicate stomach if given in sufficient quantities. When pure, I have never seen an ill effect from it whatever.

ANOMALOUS LOCATION OF THE KIDNEY.

Dr. E. W. Morgan, of Chicago, writes: "I believe the following anomalous location of the right kidney worthy of record. The subject, a female of about twenty-five years, was a college cadaver, of which I can find no life-history. The left kidney was normal in every respect. The right kidney was also normal as regards shape and structure, but lay, slightly curved, upon the left sacro-iliac synchondrosis, the hilus being directed to the vertebral line. The renal arteries were two in number, one arising from the abdominal aorta, one-half inch above its terminal division, the other from the uppermost portion of the right common iliac. The ureter accompanied its fellow to the bladder, where it turned aside to reach and open into that viscus at its usual location."

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

New York, July 7, 1888.

THE TREATMENT OF BRONCHITIS IN THE AGED.

Among the diseases to which old people are subject, one of the most common, and also the most fatal, is bronchitis. The report of the Collective Investigation Committee of the British Medical Association, prepared by Professor Humphrey, showed that, of living persons over eighty years of age, about twenty per cent. were suffering from bronchitis, and the affection is also assigned as the cause of death more often than any other malady. The unusual fatality attending the disease in the aged is due, in great measure, to the want of elasticity in the chest-walls. Expiration is thereby seriously impeded, and the expulsion of mucus from the air-passages is rendered more difficult. A continual source of irritation being thus present, exacerbations of the inflammation readily occur, and the disease is then prone to invade the smaller bronchial tubes. The treatment suggested by Professor Humphrey, as likely to afford the most relief, is some combination of sedative with stimulant remedies.

In an article in *Der Fortschritt* of January 20, 1888, Dr. Wyss reviews some of the more recent remedies employed in the treatment of bronchitis, with special reference to their use in the disease as it occurs in the aged.

Naphthaline possesses stimulating properties similar to those of camphor, and is at the same time an efficient expectorant. The remedy may be employed in the form of inhalations along with the vapor of water, or it may be given internally in capsules. For the latter, the writer prescribes a dose of 1½ to 3 grains two or three times a day. It is necessary, however, to watch the effects of the drug very carefully, for it has a tendency to irritate the kidneys, and also not infrequently interferes with the nutrition of the eye, leading to cataract, to which the aged are sufficiently prone without the added danger from naphthaline. It is further, when administered for long periods, apt to produce a noticeable degree of emaciation.

Terpine is another remedy which has acquired some reputation in the bronchitis of old people, and which, it is claimed, is free from these objectionable features of naphthaline. When given uninterruptedly for long periods, however, it is apt to excite gastro-intestinal disturbances. In order to prevent this as far as possible, the drug is given in doses of 1½ to 3 grains in pills, three times a day, during or immediately after meals.

The third remedy noticed by Dr. Wyss is terpinal, which possesses none of the disadvantages of the two preceding drugs. It is an excellent expectorant when given in doses of 4 grains, three or four times a day, in pill or capsule.

Lippia mexicana has also been recommended as one of the best expectorant and sedative remedies that we possess, being especially valuable in those cases of bronchitis in which the cough is frequent and exhausting.

Finally, the author refers to menthol, which, he says, has given him excellent results in the bronchitis of the aged when employed in the form of inhalations. It not only liquefies the mucus and facilitates its expulsion, but also acts as a sedative to quiet the violent attacks of coughing which so weaken these already debilitated patients. Dr. Wyss uses an inhaler, resembling somewhat a Turkish narghileh, by means of which, he claims, he is able to introduce the drug mixed with the vapor of water into the bronchi, and not simply as far as the larynx, as is the case with most inhalers.

THE AMERICAN MEDICAL STUDENT.

An address upon "The American Medical Student," recently delivered by Professor Austin Flint, before the Alumni Association of Jefferson Medical College, commands attention as coming from a gentleman who has had a long and successful experience as a medical educator.

Dr. Flint regards a preliminary education, including a good English education, a fair knowledge of mathematics, and a little Latin, as very nearly indispensable for the medical student. This is certainly not a very strained view of the case. He recognizes the fact, as does every educator, that the procrustean tests of fitness for being a medical practitioner are not satisfactory. There must always be different grades of students and doctors, with great divergence in natural aptitudes, social and educational qualifications. We have one examination and one degree for all. The French recognize this, and they license *officiers de santé*. The English also give the apothecaries' license. In this country colleges might give special diplomas, but it is not likely that the plan would become popular. The American people are learning, however, to recognize the fact that there are uneducated as well as educated physicians.

Professor Flint thinks that one of the most important changes to be made in college requirements is the abolition of the private instructor. He says: "Most students learn so little from their preceptors, so called, that the certificates of three years' study, as a general rule, actually represent nothing. A busy practitioner has no time to devote to his students, and rarely gives them any systematic instruction. In the great majority of instances, the country practitioner who takes students into his 'office' exacts of them little services not always of a professional kind, puts into their hands old editions of medical works, and tells them to read; this being the beginning and the end of the functions of the preceptor." Some statistics are given showing the higher marking of students who have spent one or more full years at a medical college, as compared with those who have studied under preceptors.

Instruction by lectures, Dr. Flint thinks, "is the ideal form of teaching."

This statement is made close upon his statistics showing the higher marks of students who take the recitation term! We believe it is a most misleading assertion. The lecture is most useful in some branches of didactic study; it is almost a nuisance in certain others, such as anatomy. We doubt if the didactic lecture will ever be entirely dispensed with, but it will certainly in time be made subsidiary to the recitation, and the practical laboratory and clinic work. There is not a medical graduate who has taken a good "quiz" course who will not admit having learned more from his quiz-master than from his professor.

Dr. Flint reiterates the view which his father always held, that the medical student should, from the very beginning, attend clinics, and see all of practical medicine possible. The positive opinion of these two distinguished educators upon a somewhat mooted point is of value.

Three years is thought sufficient to equip a student for the general practice of medicine. But it is not expected that a graduate, after a three years' course, will be proficient in the technique of the specialties.

"It is an error to attempt to teach, thoroughly and exhaustively, even the legitimate specialties, such as ophthalmology and otology, in the ordinary curriculum of a medical college. Nevertheless, students should receive such an amount of instruction in the so-called special subjects as will enable them to recognize the diseases of all organs of the body and make no blunders in diagnosis and treatment."

A chair devoted to the history of medicine is thought to be decidedly needed by the modern medical college.

Professor Flint expresses the natural opinion that "State medical boards, appointed to determine by actual examination the qualifications of applicants for license to practise medicine, can never be of any great practical benefit so long as it is deemed necessary to recognize, in their organization, certain so-called systems of practice, such as homœopathy and eclecticism."

This is an opinion which is purely an opinion, and is quite offset by the actual facts. There has been no single factor in promoting educational reform more potent than one of these same State medical boards. Eclecticism and homœopathy die out with the increased intelligence of the people, but we need not wait for the *rigor mortis* before attempting improvements in the regulation of medicine and status of the physician.

Professor Flint would like to see a new association of medical colleges formed, which should have for its objects:

1. The establishment of a uniform standard of preliminary education.

2. The requirement of a three full years' course of study, with abolition of the preceptors' certificates.

3. The abolition of medical colleges insufficiently equipped for purposes of medical teaching.

There are ninety regular medical schools in the country, but nearly one-half of the graduates come from only twelve of these. There are thirty colleges which graduate not over twelve students each.

Professor Flint's address, as will be seen, is a most suggestive one, and deserves the attention of all interested in educational progress. He is inclined, on the whole, to favor the view that reforms will come from within the colleges rather than from without. Those who have no personal interest in special colleges, while admitting that much can and will be initiated in this way, are also very confident of the value of outside influences. The past ten years have seen great progress in our medical schools, but it has been very largely due to the active exertions of the medical press and of non-educational organizations of medical men.

HOFMEISTER ON DIABETES.

A PHYSICIAN who practises at Carlsbad, and who concludes his article on the treatment of diabetes by saying that "strict diet and Carlsbad waters, drunk at the place, form the best method of dealing with the disease," lays himself open to the charge of personal bias. Nevertheless, the Carlsbad physicians undoubtedly have a very large personal experience in this treatment of diabetes, and the opinions of Dr. B. Hofmeister, who is a practitioner at this resort, will be read with interest. Dr. Hofmeister has some positive views regarding diabetes. First of all, he asserts that "we know nothing of its etiology." This is a somewhat radical statement, and while it may be true for the writer, is certainly not so for the profession in general. If he had said pathology instead of etiology, he might more easily have defied contradiction.

Another proposition of Dr. Hofmeister is more easily accepted. He does not think that the amount of sugar in the urine is necessarily an index of the seriousness of the case. He doubts the value of absolute diet and of the gum and gluten breads, which latter are always more or less indigestible. Finally, he has little to say of drugs, and nothing at all of arsenic, bromides, and jumbol. He formulates his views as follows:

1. The dietetic and hygienic regimen ought not to be totally changed in a sudden way. Sweet things must be at once forbidden; the amylaceous food should at first be confined to vegetables of all kinds, except the leguminous ones, and bread, 100 grammes of which may be allowed, this quantity being gradually reduced to 60 grammes, and so on.

2. Pure fat and fatty meats are highly to be recommended for their great efficacy against congenital predisposition to diabetes; 150 to 100 grammes may be allowed daily.

3. An exclusive meat diet (Banting treatment) is rather dangerous in diabetes, because it strongly promotes the disintegration of albumen, that is to say, emaciation.

4. All substitutes for bread are objectionable, partly because they contain a considerable amount of starch, and partly because they are all more or less indigestible. Fürbringer's gum bread (*Kleberbrot*), manufactured by Basserman, at Mannheim, seems to be the least injurious of these.

5. Diabetics ought to masticate perfectly each bit of food, eating slowly, in order to mix the food completely with the mucus of the mouth.

6. In all cases in which a somewhat larger indulgence with regard to the diet is admissible, all sorts of vegetables, including the sweet ones (turnips, carrots, cabbages, etc.), only excluding the leguminous (peas, beans, and lentils), are permitted, likewise raw kernel fruits and berries.

7. Milk and wine should be allowed only in small quantities, even in mild cases; half a pint of each daily should be looked upon as the maximum dose. All sorts of beer must be forbidden under all circumstances.

8. Exercise is much indicated, especially as long as farinaceous food is partly allowed. The best time for it is immediately after dinner, and it should be continued for at least two hours. Riding on horseback and hill climbing (if the ascent is not too steep) are certainly preferable to gymnastic movements indoors; but when outdoor exercise cannot be taken we are now in possession of a good substitute, I mean the "ergostat," recently invented by Professor Gärtner, of Vienna. Patients who, in any stage of the disease, are easily fatigued by the least muscular exertion, will derive great benefit from daily massage of the whole body for twenty minutes (Finkler).

9. Warm baths, as the best means of keeping the function of the skin in order, are very beneficial to sufferers from diabetes, provided that they are used at a temperature of 93° to 94° for fifteen minutes, not oftener than twice a week.

10. The mineral waters of Carlsbad are undoubtedly of the greatest use in the dietetic and medical treatment of diabetes; their effect is mostly due to the alkaline salts they contain.

11. Among the innumerable drugs recommended for diabetes, there are but few worth mentioning. In the first place, there is opium, the tolerance of which by diabetic patients is remarkable and inexplicable. Opium makes the sugar disappear; it diminishes abnormal tissue-waste, and consequently increases the weight of the body; it causes neither narcosis nor constipation in doses which would be positively dangerous if given in other diseases. Still more efficacious is morphine, in doses of from one to three grains daily. The beneficial effect of these drugs, however, does not last very long; after three or four months they lose their effect, and there is, moreover, the risk of the opium habit becoming confirmed. They should, therefore, be taken only at long intervals, and under strict medical supervision. Salicylic acid, phenol, and salicylate of sodium, are far less useful.

THE REMOVAL OF A TUMOR OF THE SPINAL CORD.

The case of successful removal of a tumor of the spinal dura by Mr. Horsley and Dr. Gowers, has already been referred to in these columns. At a recent meeting of the Royal Medical and Surgical Society, the case was reported in full. The patient had had for four years a nearly constant pain under his shoulder-blade, with long fits of agony that maddened him. Paralytic symptoms also developed. A diagnosis of spinal tumor in the neighborhood of the fifth dorsal vertebra was made by Dr. Gowers. The spinal column was laid bare, and the spinous processes removed by a bone-forceps from the third to the sixth, inclusive. The ligaments were cut through, the dura mater slit open, and a tumor shelled out. The wound healed by first intention, and the patient slowly but surely recovered. The operation was a difficult, brilliant, and epoch-making one. Mr. Horsley's researches into literature and museums showed that, of fifty-seven similar cases removal of the tumor was the only treatment, and that if it had been resorted to eighty per cent. should have recovered, instead of which all died.

A Monument to Cohnheim was recently unveiled at Leipzig.

News of the Week.

A New Method of Treating Diseases of the Respiratory Organs.—The Paris correspondent of the *Therapeutic Gazette* writes: "A new medication is now introduced. It consists in diffusing various gases or vapors in the atmosphere breathed by the patient. The apparatus is based on the principle, long known, of Davy's *glow-lamp*, whereby a coil of platinum tipped with spongy platinum, on being placed round the wick of a spirit-lamp, the alcohol set on fire till the wire becomes red-hot, and the flame then blown out, the wire and platinum black will continue to glow for a considerable period. The combustion thus produced is imperfect, and sets free quantities of ethereal and ozonized vapors, which it is now proposed to utilize for medical purposes. Dr. Onimus, an electrician of some note, has had the idea of using, besides plain alcohol, ether, petroleum, benzine, and various tinctures for feeding the lamp. The different liquids, when not medicated, sensibly afford similar combustion products—namely, aldehydes, ethereal and ozonized compounds—very useful for disinfecting purposes. But when advantage is taken of the solvent power of the feeding liquids, Dr. Onimus thinks many complaints may be relieved without chance injury to the stomach. For instance, with an alcoholic or ethereal tincture of terpine, terebene, eucalyptol, or aconite-root, coryza, bronchitis, hay-fever, etc., are rapidly benefited, and the mucous discharges will speedily cease. At the same time it must be confessed that, while the local symptoms improve, the general, such as fever, etc., are less amenable to the vapor treatment. Two consumptives experienced great relief from inhalations with an alcoholic solution of terpine and one per thousand of corrosive sublimate. Oil of thyme dissolved in benzine proved very effective for consumptives and also for asthmatics, although, for the last, tincture of belladonna afforded better results."

Mint as an Anæsthetic.—Peppermint water, the last new antiseptic, is said to be, like carbolic acid itself, a useful agent for producing anæsthesia, or, at any rate, diminishing hyper- or dys-æsthesia of the unbroken skin. Dr. Armand Routh reports very favorably on its use in pruritus pudendi, especially in the neurosal form observed frequently during pregnancy, or at the climacteric. He orders a teaspoonful of borax and five drops of ol. menth. pip. to be put into a pint bottle of hot water, and well shaken; the parts affected to be freely bathed with a soft sponge. The soothing effect often lasts for many hours.—*Philadelphia Medical Times.*

Calcium Sulphide, in Leucorrhœa of milder types not depending on ulceration, is a very potent drug, according to Dr. M. Wilson (*Therapeutic Gazette*). It is to be given in doses of gr. j. to gr. iij., night and morning.

Phenacetin as an Anodyne.—Phenacetin seems likely to prove a successful rival of antipyrin and antifebrin, not only as an antipyretic, but as an anodyne. Professor Rumpf, of Bonn, reports in the *Berlin. Klin. Wochen.* of June 4th, successful results from its use in vaso-motor neuroses, against the pains of tabes dorsalis, and in neuralgias and neuritis. He gives it to adults in doses of gr. viij., as an antipyretic, and in double that dose as an anodyne. It is not a narcotic.

HYDROPHOBINE.—It appears that we are likely to have in time the chemical virus of infectious diseases in accessible form for study, nomenclatural treatment, and pathological experiment. M. Peyraud, of Libourne, has discovered and isolated a substance which he calls "hydrophobine." This he has obtained from the brains of mad rabbits. MM. Charrin Roux and C. Cumberland have, it is said, discovered the chemical virus of several other infectious diseases.

DIAGNOSIS AND SUCCESSFUL REMOVAL OF A PANCREATIC CYST.—Professor Kocher has recently successfully removed a pancreatic cyst from a man aged thirty-seven (*Correspondenzblatt f. Schw. Aerzt*, May 1). This is the seventeenth case in which such a cyst has been operated upon, but only the third in which the disease was correctly diagnosticated before operation.

A PLEASANT COMPANY OF DOCTORS.—The doctors of Indianapolis, writes Dr. I. N. Love (*Weekly Medical Review*), are numerous but "evidently prosperous, nearly all having offices in the business centre of the city, which in their appointments and general aspect suggested thrift and plenty to do. They themselves had a uniformly well-fed, well-posted, well-to-do look; their pleasant countenances indicating good digestion, good bank accounts, and good consciences. An observation of the mutual good-will prevalent among them would in itself have been evidence that the majority are 'medical society men.' The doctor 'with the big round head,' who disbelieves in medical societies, was not apparent, and I am inclined to the opinion that he is not indigenous to Indiana soil."

THE SECOND SESSION OF THE INTERNATIONAL MEDICAL CONGRESS OF AUSTRALASIA will assemble at Melbourne, Victoria, on January 7, 1889, and the sittings will continue on the five following days. The President of the Congress is Mr. T. N. Fitzgerald, F.R.C.S.I.; the Treasurer, Dr. George Graham; the Honorary Secretary, Professor H. B. Allen; and the Associate Secretaries, Drs. J. W. Barrett and G. A. Syme.

THE RESULTS OF THE TREATMENT OF CANCER OF THE LARYNX.—Dr. Max Scheier, of Berlin, has made a tabular analysis of all the reports of cases of laryngeal cancer, one hundred and twenty-five in number, published since 1880 (*Deut. Med. Wochensch.*, June 7, 1888). There are six tables, each presenting the results of different modes of treatment. The first table comprises cases in which no operation was done—4 cases, all fatal; the second, cases in which tracheotomy alone was done—17, all fatal but 3; the third table gives the cases in which laryngotomy with extirpation of the tumor was performed, 9 in number—in 3 death ensued within fourteen days, in 3 there was relapse, 2 had shown no relapse within the first few weeks, and 1 remained well nearly three years afterward; the fourth table gives the partial extirpations of the larynx, 23 in number—2 died soon after operation, 3 about a month afterward, 5 survived operation but relapsed later on, 8 are reported as cured but not observed long enough as to relapse, and 5 remained well sixteen months and more after operation. One of the latter cases showed no relapse two years after operation, another three years, and another seven years. The fifth table gives the cases of total extirpation of the larynx, 68 in number. Of these, 18 died within a fortnight, and 5 more soon afterward; 17 survived the operation, but relapsed within a year (one excepted, but fatal in the second year); 6 died of intercurrent diseases; 13 are reported cured, but not observed a sufficiently long time to determine as to relapse; and 9 remained free from relapse sixteen months and longer. Lastly, the sixth table gives the cases in which an endo-laryngeal operation was performed, 4 in number. In one swallowing was painless eight days afterward, the second died in an epileptic fit five months afterward, the third case affords no data as to the operation, the fourth (B. Fränkel's case) underwent several operations, and remained quite well four years after the last, with a good voice. Dr. Scheier requests the various operators to favor him with the further results in the several cases mentioned in the tables, so far as known up to the present.

SEWING UP THE LIVER.—Recent exchanges chronicle the fact of successful removal of part of the pancreas, of a tumor from the spinal cord, and finally of a suturing of the liver. An Italian, aged twenty-eight, received a stab wound which made a cut just below the right costal margin, two inches long, extending into the left lobe of the liver to the depth of over an inch, and making a longitudinal cut in that organ of two and a half inches in length. Professor Postempski (*Riforma Med.*, June 9; *British Medical Journal*), who had satisfied himself so far back as 1885, by experiments on dogs, that the liver-substance could be stitched without giving way, determined to try that mode of treatment. He accordingly enlarged the wound in the skin by five centimetres, and made a second vertical incision in the middle line across the first. The wounded lobe was pushed forward as far as possible, and, while the pieces of sublimated gauze with which the wound had in the first instance been plugged were being withdrawn, six points of chromicized catgut suture were passed through the whole depth of the wound with extremely fine curved needles. The sutures were very carefully tightened as they were introduced, the edges of the wound being at the same time gently pressed together, so that the loop of catgut did not draw them into contact, but merely kept them in apposition. The sutures were tied in a simple knot, and there was not the slightest laceration of the liver-substance through which they were passed. Hemorrhage ceased at once, but the critical condition of the patient made it impossible to wash out the peritoneal cavity at all thoroughly, and Dr. Postempski believes that the greater part of the extravasated blood remained in the abdomen. There was no rise of temperature, however; but, on the second day after the operation there was very abundant albuminuria, which lasted for twenty-four hours, when it completely ceased. The patient got up on the eighteenth day, and he is now perfectly well, without any local pain, or any appreciable enlargement of the liver.

A POINT IN DIAGNOSIS—APPLICABLE ONLY TO BABIES.—Do you wish to ascertain the health of a baby, feel the condition of its buttocks. If these are firm and elastic, the baby is strong and well; if they are soft, as if they were boiled turnips in a bladder, the child is out of sorts.—*Texas Medical Journal.*

Society Reports.

THE MICHIGAN STATE MEDICAL SOCIETY.

Twenty-third Annual Meeting, held in Detroit, June 14 *and* 15, 1888.

THE Michigan State Medical Society was called to order at ten A.M., Thursday, June 14th, for its twenty-third annual meeting. After prayer by Rev. Dr. A. H. Kellogg, and the usual address of welcome by the mayor of the city, the Society proceeded to transact business.

The Secretary, **DR. GEORGE DUFFIELD**, reported the present membership of the Society at 275; that 810 copies of the "Transactions" of the last meeting had been prepared, and 500 distributed, at an average cost of seven cents per copy. He further stated that this is the first State Society to divide into sections.

The Treasurer, **DR. H. B. HEMENWAY**, showed gross receipts, $920.76, and expenditures, $848.82; leaving a balance on hand of $71.94.

The Committee on Necrology reported the deaths, during the year, of Dr. Douglas A. Joy, of Marshall, and Professors A. B. Palmer and E. S. Dunster, of Ann Arbor.

The afternoon was taken up with section work under the following chairmen: Practice of Medicine, Dr. A. W. Alvord, Battle Creek; Surgery, Professor Donald Maclean, Detroit; Obstetrics and Gynecology, Dr. George E. Ranney, Lansing.

BAD DRAINAGE AND PHTHISIS.

The discussion in the first section upon the general subject of phthisis was unanimously agreed to be one of the most profitable for many years. It was preceded by an illustrated paper by Dr. Samuel P. Duffield, health-officer of Detroit, upon the "True Principles of House Drainage."

PROFESSOR HENRY F. LYSTER, of Detroit, attempted next to show that

UNDRAINED LANDS PREDISPOSE TO PHTHISIS PULMONALIS,

the idea being that the damp and cool atmosphere of such sections increased the tendency to lung troubles, and especially to that called commonly consumption. He partially supported his views by some figures and histories of cases. On the other hand, various members of the Society reported a marked decrease in the quantity of phthisis since the land of their section had been drained.

THE TUBERCLE BACILLUS.

DR. J. FLINTERMANN, of Detroit, gave a long and carefully written compilation to show that Koch's tubercle bacillus is the cause of tuberculosis. In marked contrast came the paper of Professor Heneage Gibbes, the new member of the faculty of the Michigan University Medical School. His theme was

ACUTE MILIARY TUBERCULOSIS,

and his paper showed not only careful reading, but also thorough and unbiassed investigation and thought. He stated that in general the same reasoning would apply to phthisis and tuberculosis. The points discussed were: 1, The histology of the lesions and their bearing on the views held as to the unity of phthisis; and, 2, the relation of the tubercle bacillus to these morbid changes. He showed two specimens of lung taken from typical cases of acute miliary tuberculosis in children of about the same age, each specimen being injected with Berlin blue. Their gross appearances and the clinical history of the cases were very similar, indeed almost identical. With the microscope all resemblance ceases. [Here he showed micro-photographs, and he had also sections of the same lungs under the microscope.] In the first there is a nodule of disintegrated lung substance similar to a pyæmic abscess. In some of the nodules the process has continued longer and the central portion become caseous. All lesions in this lung were of the same character, and are similar to those of broncho-pneumonia. It is the catarrhal inflammation in which the walls of the air-vesicles and blood-vessels are included; there is interruption of blood-current and breaking down of the tissues. There is no new structural formation.

In the second specimen the whole nodule is made up of fibroid tissue containing one or more giant-cells. In the larger nodules the centre is often necrosed. The nodule is not, as some say, avascular, but the author found invariably that with the growth of new tissue new vesicles form; but in nodules with necrosed centres these exist only in the outer fibroid area, showing, he thinks, that the necrosis is due to defective nutrition. Though in the first form there is local inflammation, in the second there is no inflammation, but a formation of new tissue containing multinucleated cells of the epithelial type. Another point of difference is that in the tubercular form the disease is general throughout the body. In tuberculous meningitis, for example, true tubercle is found. In the acute caseous form the morbid process is chiefly confined to the lungs.

By other stains to bring out the tubercle bacillus it is found that the first lung contains large numbers of the characteristic bacilli, especially in the centre of the caseous nodules; and in the newer nodules, or in the edges of the caseous nodules, the bacilli are less abundant. In the second lung but a single bacillus could be found, after many hundred sections. In true tubercle he has sometimes found a few bacilli, but never in the caseous centre, always in the fibroid tissue.

The reasons for believing the bacillus to be the true virus of phthisis are:

1. It is found in persons suffering from the disease.
2. Pure cultivations reproduce the disease.
3. In the inoculated the bacillus is again found.

1. He has clearly shown that in true tubercle many cases contain no bacilli. He therefore concludes that in true tubercle the presence of the bacillus is accidental.

2. Taking the bacillus of jequirity for an example, the reproduction of the disease may be (as shown by Klein) due not to bacilli but to a chemical poison.

3. As the result of six years' experiments in inoculating and feeding various animals, he has been unable to find a bacillus in the commencement of tubercle.

He called attention to the fact that the description of Watson Cheyne's experiment showed that he was dealing with bovine tuberculosis, which greatly differs from human tuberculosis.

He concludes: 1. That phthisis and tuberculosis are distinct in their causation.

2. That the tubercle bacillus is not yet proved to have any causal relation to either, but rather seems to be a concomitant of the process of caseation.

At 7.30 P.M. the Opera House was well filled with citizens, as well as members of the Society.

PRESIDENT THEO. A. MCGRAW, of Detroit, gave an unusually clear address upon the

DEPENDENCE OF THE MEDICAL PROFESSION ON THE PEOPLE.

National peculiarities affect the professional life as much as the political. Our professional schools are distinctive, and must remain so. American medical education is a direct descendant from the English methods of a century ago. In discarding features objectionable to American institutions, we have in some cases preserved the features most objectionable to genuine education. The modern preceptor little concerns himself with preliminary qualifications, or with the actual progress of the student.

The State owes it to her citizens to provide the highest and best professional education. If she does not provide this in an institution under State control, she should make it possible for private individuals to support such a school. Colleges become useful largely in proportion to their age and to their endowment. In a State like Michigan, where the corporate life of an institution is limited, by the Constitution of the State, to thirty years, either age or sufficient endowment is impossible. It is the duty of the community to provide not only education in the schools, but also, what is of full as much importance, hospital training. Hospitals should bear a legitimate ratio to the population, and it is detrimental to the community to undertake, by public or private means, the support of more hospitals than are needed. No hospital is too well equipped. It would be far better to endow more fully hospitals already existing, than to increase their number.

Dr. George K. Johnson, of Grand Rapids, then gave the annual address in medicine, taking for his theme the

NATURAL HISTORY OF DISEASE.

Speaking generally, the natural course of a disease is toward recovery. We should discriminate closely between recovery and cure, and be careful how we use the latter word.

Professor George E. Frothingham, of Ann Arbor, next delivered the annual address in surgery, giving a history of

SURGERY AS AN ART AND A SCIENCE

to the present time, and making a plea for the extension of the course in the surgical school to four years, the first two being preparatory and the last two purely clinical.

Friday morning, the Society was called to order at nine o'clock.

THE FOLLOWING OFFICERS WERE THEN ELECTED FOR THE ENSUING YEAR:

President, S. S. French, Battle Creek; First Vice-President, Charles N. Lewis, Jackson; Second Vice-President, E. B. Ward, Lanigsburg; Third Vice-President, David Inglis, Detroit; Fourth Vice-President, Simeon Belknap, Niles; Secretary, George Duffield, Detroit; Treasurer, H. B. Hemenway, Kalamazoo; Members of Judicial Council, William Brodie, F. K. Owen, and J. H. Bennett; Delegates to British Medical Association, Theo. A. McGraw, H. A. Cleland, and C. J. Lundy; Delegates to Medical Society of Ontario, J. J. Mulheron, Donald Maclean, and C. George. Kalamazoo was selected as the next place of meeting, on the second Thursday in May, 1889.

Professor N. W. Webber, of Detroit, gave an annual address in gynecology on the subject of

UTERINE DISPLACEMENTS.

In the afternoon sectional work was resumed, and at that time the following officers were elected: In Section on Practice, Chairman, Dr. Hugh McColl, Lapeer; to give Annual Address, Professor H. F. Lyster, Detroit; Committee on Physiology, Dr. W. C. Wade, Holly; Committee on Hygiene and Climatology, E. L. Shurley, Detroit; Committee on Pathology, Heneage Gibbes, Ann Arbor; Committee on Materia Medica, C. George, Ann Arbor; Section on Obstetrics, Chairman, Dr. E. W. Jenks, Detroit, Address.

In the Section on Practice, among the papers read was one by **Dr. A. M. Hume**, of Owosso, upon

AN INORGANIC MITRAL BRUIT,

which he thinks is caused by irregular cardiac contraction, thus preventing exact apposition of the valves.

It was generally agreed that the time for the meeting was too short. The sectional work was well done. Harmony prevailed throughout the entire meeting, if we may overlook the persistent attempts of one of the old members to "'bolish this section nonsense."

Entertainments were provided, fine and interesting, but they were not permitted to interfere with scientific work. In all, over thirty papers were presented, and all of a high order.

ONTARIO MEDICAL ASSOCIATION.

Eighth Annual Meeting, held in Toronto, Canada, June 13 and 14, 1888.

(Reported by our Canadian Correspondent.)

The eighth annual meeting of the Ontario Medical Association opened in the theatre of the Normal School, Toronto, on Wednesday, June 13th, the President, **Dr. J. W. Rosebrugh**, of Hamilton, presiding. The attendance was about two hundred, and represented every portion of the Province of Ontario.

THE PROVINCIAL LIBRARY.

Dr. J. E. Graham, of Toronto, presented the report of the committee appointed to draft a scheme for the establishment of a provincial medical library. The committee had secured very suitable rooms in the new and elegant building of the Ontario Medical Council, and the Toronto Medical Society had donated a liberal sum to the library. They had considered it advantageous to form a joint stock company known as the Ontario Library Association, with shares at five dollars each, payable in five annual instalments, and had already subscriptions in stock amounting to four thousand dollars. Numerous gifts had been offered from friends in the United States, but these were cumbered by the duty on books, an unjust tax that the committee urged the members of the Association to agitate for removal. Although they had not canvassed for books, they had received eight hundred bound volumes and some seven thousand pamphlets and magazines. In closing, the report appealed to the Association, individually and collectively, for support.

On motion, it was resolved to donate one hundred and fifty dollars to the Ontario Medical Library.

RECEPTION OF DELEGATES.

Dr. G. H. Fox and Dr. C. C. Rice, of New York; Dr. A. W. Johnstone, of Danville, Ky., and Dr. Gardner, of Montreal, were introduced as delegates to the Association. They were each accorded a warm welcome, and, in short addresses, acknowledged the cordiality with which they were received.

PRESIDENT'S ADDRESS.

The President, **Dr. J. W. Rosebrugh**, of Hamilton, then delivered his address. After expressing his appreciation of the honor bestowed upon him in his election to the office, he reviewed the history of medicine and medical education in the Province of Ontario, and mentioned the names of several of the fathers of the profession to whose zeal and devotion too much praise could not be given. After congratulating the Association on the success which had attended it since its formation, he suggested that it might be well to consider the propriety of affiliating with the British Medical Association, which has now over twelve thousand members and forty-seven branches, and under whose auspices was published the *British Medical Journal*. He referred to the history of medical science, and said that science was still largely empirical, but that the truth was becoming more and more firmly established that all the modes and methods of nature must be studied and obeyed. In conclusion, he expressed his gratification at the continued improvements in medical education, and urged the co-operation of all in promoting the various schemes for perfecting the educational advantages now enjoyed by the Province. The higher the standard was raised, he concluded, the better would it be for the student and his patients.

SURGICAL SECTION.

Dr. Grassett, of Toronto, opened the discussion on Surgery by reading a paper on

URETHRAL DISCHARGES,

in which he referred to the various diseases of the urethra, their causes, pathology, and treatment. Regarding the treatment of gonorrhœa, he deprecated the use of injections, and spoke of the advantages gained in the use of bougies in those cases. He was followed by **Dr. McFarlane**, of Toronto, who considered that it was a shame that in our public schools the male pupils are not taught and warned of the baneful effects of masturbation. He strongly advocated the necessity of a plain explanation being given, so that our young people might learn how disastrous it was to their mental and physical welfare to indulge in vicious practices. Dr. Groves, of Fergus, Dr. Burt, of Paris, and Dr. Dupuis, of Kingston, continued the discussion.

SOFT MYOMA.

Dr. A. W. Johnstone, of Danville, Ky., then read a paper on "Soft Myoma," illustrating his subject by a drawing of a tumor of this kind which he had recently removed. The object of the paper was to show that this form of uterine tumor is not one of the secondary changes of the hard myoma, due to degeneration of the newly-formed muscular tissue comprising the ordinary fibroid, but is an entirely distinct tumor, springing from a different source, having a separate histological and clinical history, and a widely different termination.

BACTERIA.

The next paper was by **Dr. Charles Sheard**, of Toronto, on "Bacteria and their Influence on the Blood and Tissues." After reference to the importance of the part played by bacteria in disease, he proceeded to speak of typhoid fever, and expressed the opinion that too much stress was laid upon temperature in diagnosis. He questioned the soundness of the principle that increase of temperature meant fever, and that the lowering of it really meant a reduction of the fever. His conclusions were (1) that, save in those cases where death takes place from the action of the typhoid fever poison directly on the nervous system, there must be intestinal lesion to prove the existence of typhoid; (2) that with such intestinal lesion we will have distinct abdominal symptoms; (3) that acute tuberculosis and septicæmic states are often mistaken for ordinary typhoid; (4) that the evening rise and morning fall of temperature as a proof of the existence of typhoid is deceiving. An interesting discussion followed by Dr. Mullin, of Hamilton, Dr. Henderson, of Kingston, and Dr. Smith, of Tilsonburg.

EMPYEMA.

The next subject was Empyema, in the discussion of which Dr. Holmes, of Chatham, and Dr. Whiteman, of Shakespear, took part.

OTHER VISITORS INTRODUCED.

The President introduced several visitors to the Association.

The Hon. Charles Drury, Minister of Agriculture, said he always regarded medical men in politics as valuable friends and formidable opponents. He was glad to note the great advances made in medical science, and the evident disposition of the Government to deal liberally with the Profession.

The Hon. George W. Ross, Minister of Education, spoke of the good work done by the medical profession in securing for the country excellent sanitary conditions and laws, and also alluded, in high terms of praise, to the high standard required of those aiming at getting the diploma of the Ontario Medical Council, without which no one was allowed to practise medicine in this province. He would be willing to render all manner of assistance to the Council in effecting further reforms and substantial improvement. Young men were finding to their cost that Ontario was a country where superficiality is discarded, and where thoroughness is especially desired by those acting in the best interests of medical science.

Dr. J. H. Barns, President of the Medical Council of Ontario, was introduced, and said he was glad to note the prosperity of the Association, the members of which were all in accord with the efforts of the Medical Council, which was now recognized as doing its best to prevent the profession of medicine from being entered by incompetent men.

Sir James Grant was also introduced to the meeting as an old and highly-respected member of the Canadian profession.

THE PATHOLOGY OF 1887.

Dr. H. A. McCollum, of London, read an able paper on "Notes of Clinical Importance in the Physiological Researches of 1887," in which he presented a succinct and interesting account of some of the chief pathological discoveries of the year.

SURGICAL TREATMENT IN NASAL DISEASES.

Dr. C. C. Rice, of New York, read an interesting paper on "The Surgical Treatment of Catarrh and other Nasal Diseases," and illustrated the subject by exhibiting and explaining the latest instruments used in operations on the nasal tract.

MALARIAL DISEASES.

"Malaria as the Cause of Disease," was treated of in an able paper by **Dr. Mullin**, of Hamilton. He said that a great many cases are diagnosed as due to malaria, while a proper and painstaking examination would show that the cause of the disease was something else. He deprecated severely the indiscriminate and too liberal administration of anti-malarial remedies, which must not be considered harmless. The paper was discussed by Drs. Geikie and Workman, of Toronto.

THE CANADIAN ANATOMY ACT.

The following resolution was unanimously adopted: "That this Association would regard with great satisfaction the modifying of the Anatomy Act by the Legislature of Ontario as soon as possible, so as to make it more efficient in promoting the advancement of medical and surgical science by securing a more adequate supply of anatomical material; the study of anatomy being the basis of all sound medical education."

BANISHING THE IRREGULARS.

The report of the Committee on Credentials was presented and created considerable discussion. Three persons who had made application for membership in the Association were rejected, one on the ground of announcing his ability to detect disease by clairvoyancy, and two for advertising freely in public prints and thus bringing discredit on the profession.

Second Day—Thursday, June 14th.

The proceedings of the second day were marked by a large attendance, and a highly interesting programme of papers and discussions thereon.

IDIOPATHIC GLOSSITIS.

Dr. Hunt, of Clarksburg, read a paper on "Idiopathic Glossitis," in which he reported a case, the only one of the kind he had met with in a practice of twenty years, and during the same period he had rarely seen a case recorded in the current medical literature. A discussion followed, in which Dr. McPhedran, of Toronto, Dr. Brock, of Guelph, and Dr. Metherill, of Freelton, took part, and each advocated the use of ice in treatment.

FRACTURES OF THE HUMERUS.

Dr. C. M. Smith, of Orangeville, read a paper on "Fractures of the Humerus," and introduced a patient wearing a splint, the claims of which he advocated for the successful treatment of those cases. The splint was critically examined by the members, and favorably commented on by some who had tested its merits.

RUPTURED TUBAL FŒTATION.

Dr. Gardner, of Montreal, one of the guests of the Association, read a paper on the above subject, in which he referred to the recent advances made in the treatment of those cases by timely surgical interference, and described an interesting case which had recently come under his notice. **Dr. Johnstone**, of Danville, Ky., congratulated Dr. Gardner on the paper he had read, and thought that both Canada and the United States should be thankful for the advance made in the science of obstetrics by the careful study and investigation of men like Dr. Gardner. The speaker referred to the danger of using electricity in order to kill the fœtus, as it so frequently resulted fatally to the mother. The knife was the best remedy, and if the patient objected to its use, he (the speaker) would throw up the case. The whole system of applying electricity was, he thought, based on an erroneous idea.

Dr. Gardner replied to the remarks made by Dr. Johnstone, upholding the use of electricity in certain cases.

NEURASTHENIA.

Dr. Daniel Clark, Medical Superintendent of the Toronto Asylum, read an interesting paper with the above title. Fear had a great deal to do with neurasthenia, which must not be confounded with hysteria, hypochondria, or insanity. Patients suffering from neurasthenia are themselves aware of their vagaries, get rid of their fears at times, but, like the swinging pendulum, return to them. They conjure up mountains of woe, and the reserves of nervous force which all possess are consumed. Many of those suffering from neurasthenia are restless, capricious in their appetites, but look fairly well. A desire to shirk duties that once were a pleasure, restless nights followed by a low condition of thought, lack of self-control, timidity, and irresolution, are evidences of neurasthenia. Many medical men made the mistake of trying to lecture patients out of their forebodings. It was better to accept them, and picture brighter things. Fresh air was invaluable in the treatment of all nervous diseases, but the cure would necessarily be slow. A large stock of patience was necessary. The disease was often caused by indulgence of secret vice and by syphilis. In treatment we cannot expect any favorable result from opium, chloral, alcohol, or in fact any other drug. Leave medicine alone, and enforce thorough cleanliness with good food, and plenty of fresh air and exercise. Cheerful company is also absolutely necessary.

UTERINE HYDATIDS.

Dr. Bray, of Chatham, read a paper on "Uterine Hydatids," giving notes of a case coming under his notice. He dwelt with emphasis on the importance of making a careful diagnosis in any case suspected to be hydatids, and related a case where, through an error, premature labor had been induced where uterine hydatids had been diagnosed.

LEUCOCYTHÆMIA.

Dr. McPhedran, of Toronto, presented a case of "Leucocythæmia," in which the splenic enlargement was well marked.

A NEW OPERATING-TABLE.

Dr. Charles O'Reilly, of the Toronto General Hospital, exhibited an operating-table of which he was the inventor, and explained its advantages. One of them was the use of a screen which hid from view the features of the patient operated upon, and the doctor explained that by its use women regarded with much less horror the idea of submitting to local uterine treatment. Dr. O'Reilly also invited the members of the Association to inspect one of the new ambulances recently adopted for use by the city of Toronto.

LIFE INSURANCE.

At the afternoon session **Dr. J. Thorburn**, of Toronto, read an interesting paper on "Life Insurance, and the Relation of Medical Men Thereto." He said life insurance is now one of the principal institutions of the civilized world, and its history is instructive. Pascal was the first to introduce the study of probabilities, but the Breslau tables, formulated by Dr. Hally, were the first of any importance mentioned on the expectation of life. In 1697 a policy was issued on the life of Sir Robert Howard for one year, and exactly that day year Sir Robert died. The merchant refused to pay on the ground that the policy had expired, but the court ruled that "from" the day of date excluded the day itself. The growth of life insurance the last thirty years had been wonderful. The medical man has many important functions to perform in relation to life insurance, for on his skill and selection the success of a company mainly depends. Gross frauds have been perpetrated on life insurance companies. Personation, forgery, murder, have been employed, and medical men have to weigh carefully the statements of applicants. Many persons of intemperate habits conceal the fact. The position of medical examiner was one of great importance. At one time applicants appointed their own medical examiner, but this soon led to trouble. Now companies appoint their own examiners and greater satisfaction is given. No medical man should accept such a position unless prepared to give his time to it and perform his duty without fear or favor. Some examiners perform their duty by a simple thump on the chest, a feeling of the pulse, etc., and such an examiner was a disgrace to the profession. The surroundings of an applicant were important, as shown by the statistics of lying-in hospitals. The lives and habits of ancestors and parents should be considered. The occupation of an applicant often shortens life, as for instance, painters and plumbers. Professional men were the best lives to insure. In connection with life insurance medical men have high moral responsibilities. This interesting paper was freely discussed, and the opinion expressed that many life insurance companies seem unwilling to show their appreciation of the services of their medical examiners by paying a satisfactory fee for the services rendered.

LAPAROTOMY.

Dr. L. McFarlane, of Toronto, read an instructive paper on "Laparotomy for Acute Intestinal Obstruction," and Dr. Yeomans, of Mount Forest, Dr. Grassett, of Toronto, Dr. Hunt, of Clarksburg, Dr. Richardson, of Toronto, and the President, discussed the paper.

THE USE OF PESSARIES.

Dr. J. A. Temple, of Toronto, then read a paper on the above subject, in which he ably advocated careful discrimination in the use of all mechanical supports, and urged the importance of giving careful consideration to the pathological conditions present before recommending the use of a pessary.

APOSTOLI'S METHOD.

Dr. A. M. Rosebrugh exhibited the uterine electrolytic apparatus employed by Apostoli, of Paris, and briefly explained the latter's method of employing these instruments in the treatment of fibroid tumors.

PUERPERAL ECLAMPSIA.

Dr. Irving, of Kirkton, had a paper on the above subject, and **Dr. A. A. McDonald**, of Toronto, followed with a paper on

THE DIAGNOSIS OF OBSCURE PELVIC AILMENTS,

in which he urged the importance of (1) fixing the seat of the disease, and (2) endeavoring to remove the cause by removal of the uterine appendages, if such were considered necessary.

AN INTERESTING REPORT.

The Committee on Medical Ethics then presented their report, which concluded as follows:

"Your committee, after carefully considering the code of ethics, as at present adopted by this Association, and which code is really that of the American Medical Association, have come to the conclusion that the time has arrived when the Ontario Medical Association should frame a code of ethics of its own, taking special cognizance of the following points brought under their observation: 1. That of signs displayed outside of churches and other public places, with the name of any practitioner painted on them. 2. That the practitioners employed by the various clubs be remunerated in proportion to the work done. 3. To signs displayed by medical men outside their houses, and to advertisements in the daily papers. 4. To the posting of handbills about the city by practitioners on change of residence. 5. To the advertisements of a certain dispensary for diseases of women in this city, notifying the public that advice was free, and that students were not admitted. 6. Your committee beg to recommend the appointment of a committee to formulate a code of ethics and to report at the next annual meeting. The seventh clause recommended the expulsion from membership of a certain member for unprofessional conduct."

The report was read clause by clause, and provoked a great deal of discussion. The first six clauses being adopted, the secretary informed the meeting that the member whose expulsion had been recommended had tendered his resignation and withdrawn from the Association.

Dr. J. H. Richardson, of Toronto, presented a paper on

CORONERS' INQUESTS.

After a few preliminary remarks dealing with the gravity of the question, the speaker suggested that a committee of the Association should be appointed to elaborate some feasible scheme for conducting investigations, in suspected cases of death, more in accordance with the spirit and conditions of an advanced civilization. He believed that the true functions of the coroner ought to be confined to throwing all the light possible on the cause of death, leaving matters purely legal to gentlemen of the legal profession. As to the medical witness, the speaker was more emphatic, condemning the superficial character of the evidence sometimes given touching the cause of death. The usual practice is to entrust the *post-mortem* examination to some medical man known to have been acquainted with the deceased, or to have been in some way accidentally connected with him at the time of death. Too little time is allowed the witness to prepare an intelligent report, and consequently in many cases the ends of justice are frustrated. If he should afterward discover that his opinion as to the cause of death was erroneous, no opportunity of putting the case right may ever arrive. A medical witness should have a thorough knowledge of medical jurisprudence, so that it is not every medical man that can be an intelligent witness of the cause of death in cases involving intricate details. As to the coroner's jury, the speaker said he had not respect enough to give it serious attention. It is absurd to believe that twelve men, sometimes gathered from the most ignorant class, can advance the ends of justice. In the opinion of the speaker, the time has arrived when the coroner's jury should be dispensed with.

A spirited discussion followed, the concensus of opinion being that coroners' inquests are in nearly all cases defective.

A committee was appointed to take into consideration the whole subject of medico-legal investigations of violent or suspicious deaths, and to draft a bill embodying the proposed changes, which will be submitted to the Ontario government on the event of the bill receiving the endorsement of the Association at its next annual meeting.

OFFICERS ELECTED.

The report of the Nominating Committee was then presented, and the following officers elected for the ensuing year:

President—Dr. W. H. Henderson, Kingston.
First Vice-President—Dr. Geikie, Toronto.
Second Vice-President—Dr. Howitt, Guelph.
Third Vice-President—Dr. Day, Trenton.
Fourth Vice-President—Dr. Aikman, Collingwood.
Corresponding Secretaries—Dr. Lovitt, Ayr; Dr. Gillies, Teeswater; Dr. Trimble, Queenston; and Dr. Leonard, Napanee.
General Secretary—Dr. D. J. Gibb Wishart, Toronto.
Treasurer—Dr. N. A. Powell, Toronto.

After passing the usual resolutions, the new president was duly installed in office, and the Association adjourned to meet in Toronto in June, 1889.

SOCIETY OF GERMAN PHYSICIANS OF NEW YORK.[1]

Stated Meeting, April 27, 1888.

Dr. George W. Jacoby, President of the Evening, in the Chair.

MARKED HYPERTROPHY OF THE TONSIL OF THE TONGUE.

Dr. Gleitsmann showed a patient with hypertrophy of the lingual tonsil. The case concerned a woman, thirty-eight years of age, who for the past two years had suffered from a troublesome cough, accompanied by constant irritation of the throat and the sensation of a hair lodged in the fauces, compelling repeated efforts at deglutition. The cough was so severe as to disturb her night's rest. For about three months the sputum had been tinged with blood. The physical examination of the chest revealed the absence of pulmonary mischief.

Examination of the throat showed enormously hypertrophied follicles at the base of the tongue, which, on the left side, impinged upon the epiglottis. Apart from this, the respiratory passages appeared normal. Minute extravasations were seen at the tip of some of the most prominent follicular glands.

The speaker also referred to a somewhat similar case previously observed by him (The Medical Record, December 17, 1887).

HEMORRHAGES HAD NOT HITHERTO BEEN OBSERVED

in this affection. The origin of the bleeding was a mechanical one, due to friction of the enlarged follicles against the adjacent parts.

Destruction of some of these follicles by means of the galvano-cautery had already resulted in an improvement of the condition of the patient.

The speaker finally alluded to

A PRIORITY CLAIM

put forth by Lennox Browne, in The Medical Record, in regard to the dependence of certain morbid symptoms upon the condition under consideration. Dr. Browne evidently referred to enlargement of the circumvallate papillæ, and not to hypertrophy of the follicles. Hence his claims were not tenable.

Dr. C. Heitzmann observed that these bodies were erroneously called glands. They were, in fact, only lymph-follicles, and should be so designated, even by the laryngologists.

Dr. Toeplitz had seen a number of cases of this kind, but did not believe that "tonsil of the tongue" was a proper name for the structures in question. One of his cases had recovered under topical applications of tannin-glycerine.

COLLOID CANCER OF SUPERNUMERARY MAMMARY GLAND IN A YOUNG GIRL.

Dr. C. Heitzmann presented a specimen of the above, which had been sent to him from Utica. The tumor was removed from an apparently healthy girl, seventeen years of age. It was situated at the border of the pectoralis major muscle, about midway between the axilla and mammary gland.

---

[1] This Society has been in existence since 1857. Monthly meetings are held on the fourth Friday of every month, except July and August, at the residence of Dr. A. Jacobi.

Microscopical examination revealed normal glandular tissue, in addition to cancer of the colloid variety.

Dr. Jacobi asked whether carcinomatous transformation was not a common occurrence in these accessory glands.

Dr. Willy Meyer believed that it was often seen in the supernumerary glands found in regions of the body more remote from the breast.

SUPRAPUBIC CYSTOTOMY FOR CANCER OF THE BLADDER.

Dr. W. Meyer exhibited fragments of a tumor of the bladder removed by the suprapubic method. The operation was done at the German Hospital, on a patient sixty-five years of age. The patient had suffered from vesical symptoms for six years. About one year ago hæmaturia was first observed. There was marked vesical tenesmus, and not infrequently small particles of the tumor were voided during an act of painful micturition. Rigors also came on. Vesical incontinence supervened two months ago; the patient was confined to his bed and because visibly emaciated.

On admission to the German Hospital, a large tumor of the bladder was readily detected by bimanual palpation. The patient had an afternoon temperature of about 102° F. The kidneys had apparently suffered but little, if at all. The capacity of the bladder was barely three ounces.

Cystoscopy was practised, but the field of vision remained dark, although the patient's abdominal structures were so thin that they appeared translucent from the electric light within the bladder. The speaker believed that

A NEGATIVE RESULT OF CYSTOSCOPY, PROVIDED THE FLUID IN THE BLADDER WAS CLEAR, SHOULD JUSTIFY THE DIAGNOSIS OF A GROWTH OF LARGE SIZE.

In the present case it proved to be so large as to fill almost the entire bladder.

Epicystotomy showed the size to be that of a man's fist. It was impossible to remove it otherwise than piecemeal. It was attached by a broad base near the opening of the left ureter. Resection of the wall of the bladder was not undertaken, owing to this broad attachment. The patient bore the operation well, and had developed no unfavorable symptoms. The operator intended to establish a permanent fistula of the bladder, in view of the probability of recurrence of the neoplasm.

COMPLETE CONGENITAL OCCLUSION OF THE RECTUM—DEATH FROM HEMORRHAGE AFTER OPERATION.

Dr. E. C. Wendt presented a specimen of complete congenital closure of the rectum, and gave the following history of the case: The infant was born at full term, after a normal labor, at the New York Infant Asylum. The anus was so well formed that the child was two days old before the atresia recti was discovered. The occluding membrane was about one-quarter of an inch above the anal opening.

Operative interference by means of puncture of the membrane, the introduction of probes for purposes of distention, and, finally, a crucial incision, gave some relief to the symptoms of incipient peritonitis. But uncontrollable hemorrhage occurred, and the infant died exhausted on the fifth day.

At the autopsy it was found that the entire colon was much distended, partly by gas and in part by a grumous substance. The latter proved to be blood mixed with meconium.

The septum which had produced the atresia was one-eighth of an inch thick. Mucous membrane was found both below and above it. The anus was well formed. There was incomplete hypospadias.

THE BONY PELVIS WAS EXTREMELY CONTRACTED;

so much so that the index-finger could barely be forced through, after removal of the soft parts. The bladder was filled with turbid urine and was very much distended, reaching half-way up to the umbilicus. The cæcal end of the rectum above the occluding septum formed a much distended pouch, and showed at one point a traumatic laceration, from which some of the hemorrhage had undoubtedly occurred. There was no other abnormality about the child, but it was poorly developed, and might easily have passed for a nine months' fœtus.

Dr. Adler was disposed to regard the case as one of imperforate anus, with more than the ordinary amount of depression of the external integument at the point corresponding to the anus.

Dr. Wendt replied that in view of the fact that the anus was quite normally developed and the occlusion concerned the rectum,

ATRESIA RECTI WAS THE PROPER DESIGNATION.

Dr. W. Meyer concurred in this opinion. He added that a study of the specimen would seem to show that an operation might have been successfully done. Certainly the septum was not uncommonly thick, and its low situation rendered it accessible to the knife.

In cases where the occlusion was situated higher up in the rectum, operative interference was quite difficult, and a regular

PROCTOPLASTY MUST BE PERFORMED.

In cases where this was impossible of accomplishment, an anus præternaturalis would have to be established. The sphincters of the anus were usually well developed in these cases. But if they were found in an opposite condition, the rectal incision would have to be more limited than otherwise.

The speaker also related

A SUCCESSFUL OPERATION

undertaken by him in a case of atresia of both rectum and anus. The occlusion of the rectum extended as high up as two inches from the anus. The infant was twenty-four hours old, and the final result of the operation was a satisfactory one.

ANEURISM OF ARCH OF AORTA—ABSENCE OF AUSCULTATORY SIGNS.

Dr. I. Adler presented a specimen of aortic aneurism, obtained from the body of a man who had died at the German Hospital. The peculiarity of the case consisted in the fact that no auscultatory evidence of aneurism could be obtained. Indeed, the diagnosis of retro-sternal or mediastinal tumor could not be excluded *intra vitam*. A short time before death the patient had developed rigors, followed by rapid rise of temperature up to 107° F., and sweats. Other

EVIDENCES OF SEPTIC INFECTION

were likewise present.

The autopsy showed that these symptoms were due to purulent softening in the interior of a thrombus situated in the aneurismal sac.

PHTHISIS OF ONE KIDNEY, WITH HYDRO-NEPHROSIS OF THE OTHER.

Dr. Adler also exhibited the kidneys and heart of a woman, aged twenty-four, who was admitted to the German Hospital in a dying condition. A clinical history was not obtained, although it was learned later that the patient had for many years presented the appearance of chloranæmia. Complete anuria was also alleged to have existed for several days before the woman's admission to the hospital.

At the autopsy the right kidney was found to be atrophic to the last degree. Even the microscope failed to reveal any remnant of healthy renal tissue. The ureter was completely obliterated. There were a number of cavities filled with a gritty substance, containing fat and lime salts. The right kidney presented the usual appearance of hydro-nephrosis with pyelo-nephrosis. The heart was very small, but the left ventricle was clearly hypertrophied.

PURPURA RHEUMATICA, ASSOCIATED WITH GASTRIC DISTURBANCES.

Dr. A. Seibert related a case of this kind occurring in a woman aged twenty-six. The rheumatic affection was held in check by salicylate of soda, given per rectum, on account of intolerance of the stomach. The attacks of vomiting accompanying the purpuric and rheumatic symptoms lasted for days. Washing out of the stomach often checked them. The speaker expressed the opinion that the mucous membrane of the stomach was probably affected by a process similar to the one observed in the integument, and which there produced the manifestations of purpura. An infectious element was possibly present in this case, since a change of domicile to more hygienic quarters resulted in recovery.

NON-FEBRILE PURULENT EFFUSION OF KNEE-JOINT IN AN INFANT, FOLLOWING OPHTHALMIA.

Dr. A. Jacobi related the following case: In one of the public institutions with which he was connected, and in which careful attention to cleanliness and disinfection was customary, a peculiar case of non-febrile purulent effusion into the knee-joint was observed. The infant was four weeks old and appeared healthy, barring an ophthalmo-blennorrhœa which had subsided at the time when the right knee-joint became affected. Aspiration showed purulent effusion, but fever never appeared. Antiseptic injection of the joint resulted in recovery. Other abscesses were not observed. The speaker believed this case to be one of atypical pyæmia, although he was aware that sepsis in infants might occur without rise of temperature.

Dr. Wendt stated that he had observed quite a number of cases of pronounced septicæmia in infants, in which the temperature had remained normal or subnormal throughout. He believed that the case related by Dr. Jacobi might be regarded as one of gonorrhœal metastasis.

Dr. A. Schapringer remarked that inasmuch as no search for gonococci had been made, the case might certainly be one of gonorrhœal infection, particularly as ophthalmia had existed in the institution in question.

Dr. W. Meyer was inclined to consider the case as an instance of cold abscess on a scrofulous basis. If the purulent effusion into the knee had had any relation to the blennorrhœa, a rise in temperature ought to have occurred.

The Origin of Diphtheria from Birds.—It has been known for some years that birds and poultry are subject to a disease which corresponds to what in the human being is known as diphtheria. Several foreign observers have gone a step further, and have endeavored to show that the disease is capable of transmission from animals to human beings. Last year Dr. Turner drew up an interesting report for the Local Government Board, bearing on this alleged transmissibility, and he adduced a large number of observations which seemed to indicate a connection between a diphtheritic affection, not only in fowls, but in rabbits and cats, and a similar affection in man. The report comprised several instances in which the "strangles" in horses appeared to give rise to a like train of symptoms. In a thesis by Dr. Menzies, the transmission of the disease from animals to man is attributed to the dejections of the former. Diphtheritic affections among fowls are very common in Italy, and he quotes an instance in which four out of the five children of a medical man were attacked and died. In this case he incriminates the thatched roof, which was inhabited by colonies of fowls, geese, pigeons, etc. The dejections of these animals, washed off by the rain, found their way into the cistern or well from which the supply of drinking-water was drawn.—*Medical Press and Circular.*

NEW YORK ACADEMY OF MEDICINE.

SECTION IN SURGERY.

Stated Meeting, May 14, 1888.

Robert F. Weir, M.D., Chairman.

Dr. B. Farquhar Curtis read a brief paper, and described, first, a case of small lipoma of the thigh, containing a carcinomatous lymphatic gland, and, second, a case of chronic mastitis with beginning carcinoma.

The Chairman would impress upon the minds of the laity, and also of the profession, the necessity for treating such cases early. The small size of the tumor and its short duration were favorable facts in prognosis. The point which the author had laid stress upon, that continued irritation was often present at the seat of the cancer, was true, and had been known even before the days of what might be called the germ theory of disease. The word irritation is, after all, only a cloak to hide some of our ignorance, and we know little more at present, further than that unhealthy or weakened structures were more likely to be attacked by germs than were healthy, or, in other words, that normal tissues resist the invasion of germs to a marked degree.

Dr. C. A. Powers then read a contribution to the treatment of fracture of the lower end of the humerus, with exhibition of cases (which will be published in a future issue).

The Chairman remarked upon the great variety of fractures and the excellent results obtained by Dr. Powers. His own custom was, like that of Dr. Powers, to give an anæsthetic whenever there was any doubt about the diagnosis, and for the purpose of obtaining as thorough a knowledge of the condition present as well as for his own protection. He joined himself to those who did not resort to early passive motion. When, however, the splint was changed, it was permissible for the surgeon to make slight motion to see that all was correct. Dr. Weir called attention to the condition called diastasis, but which more commonly was associated with fracture, and said that in certain forms of this there was impaction or locking, with decided displacement anteriorly of the upper fragment, and that, unless the surgeon were on the look out for it, the real condition would escape his notice. An endeavor should be made to forcibly crowd the upper fragment backward sufficiently to allow the arm to be thoroughly flexed. In one instance, he had to repeat his manipulations under ether a second time to accomplish this end.

Dr. J. D. Bryant said he had used plaster-of-Paris in the treatment of the class of fractures under consideration since he was interne in Bellevue Hospital, and he had nothing new to add, but would only make a stricture upon the manner of applying it. He had on two or three occasions seen undue pressure exerted upon the front part of the arm, from repeated foldings of the bandage as it crossed the elbow; but, if ordinary precautions were taken, no evil results need follow its use. He thought the results obtained by Dr. Powers were remarkably good. Dr. Bryant related a case of fracture of the external condyle of the humerus which occurred at the age of seven years in a person who, when he consulted him over a year ago, was twenty-six years of age. He had well-marked external deformity when he saw him. There was also swelling, pain, and tenderness at times; and crepitus, due evidently to structural changes in the cartilage. Passive movements caused pain, which was greatest when the articular surfaces were pressed together. Crepitus was particularly noticeable when the radius was brought in firm contact with the external condyle. His business required him to use a scroll saw, which, on account of causing pressure of the radius upon its articulating surface at the humerus, was attended by much pain. At his advice, the patient stopped work as long as his circumstances would permit, and was free from pain, but after going to work again he returned after three months for treatment. He then found that pain and crepitus did not occur when flexing and extending the arm, provided traction were made at the same time, tending to separate the articular surfaces at the elbow. Acting on this suggestion, he devised an instrument for application to the arm and forearm with a hinge at the elbow, permitting of flexion and extension, but tending to separate the articular surfaces and prevent concussion between them. It was fastened with adhesive plaster. While wearing it the patient was able to follow his occupation without pain or injurious effects upon the elbow.

Dr. Robert Abbe said the question of passive motion had been frequently discussed the past three or four years, and the opinion had been growing that, if the bones were placed in correct position soon after the accident, nature would take care of the fibrous anchylosis which attended reparative action. The important lesson to be learned was the true nature of the condition present, and etherization was absolutely necessary to get at the truth in the large majority of cases. The general practitioner was not likely to see the patients as soon after the accident as had Dr. Powell in most of his cases, and when swelling had taken place diagnosis was very difficult. Dr. Abbe had seen three cases in rapid succession about three years ago, in children from five to twelve years, who had transverse fracture. He did not see them until two, three, and five weeks after the accident. The deformity from fracture was still present in each of the cases, and flexion was stopped abruptly short of a right angle or at a right angle. He had to use considerable violence to unlock the fragments. Dr. Weir had spoken of crowding back the upper and prominent fragment. This was not possible in Dr. Abbe's experience, until after forcible lateral rocking motion, unlocking them. In applying the plaster-of-Paris splint, he overcame the objection spoken of by Dr. Bryant by making it much thicker on the posterior aspect of the elbow.

Dr. Powers closed the discussion, and said the impression seemed to prevail among general practitioners that the plaster-of-Paris splint was a very dangerous thing. It was, if applied too tightly, but when put on properly he thought it was superior to anything else. The diagnosis should be made when the patient was first seen. The majority of his cases did not come under observation until after twenty-four or thirty-six hours.

Dr. Weir approved of the use of the plaster-of-Paris splint, but he remarked upon the necessity of not applying it so as to make compression. Cotton might be placed beneath to allow of further swelling.

Dr. Bryant remarked that he would apply the splint firmly if the patient were where it could be removed at once should it prove necessary.

Dr. George B. Phelps presented a case of

COMPOUND DISLOCATION OF THE FOOT INWARD WITHOUT FRACTURE OF THE BONES.

There was rupture of the skin and ligaments. Three sutures were inserted, a Volkmann's splint applied, and drainage established. The patient had perfect use of the foot twenty-three days after the accident, and walked without a support.

Dr. F. Tilden Brown read a paper

ON THE LIMITATIONS OF ELECTROLYSIS AS A THERAPEUTIC AGENT IN ORGANIC AND SPASMODIC STRICTURE OF THE URETHRA.

The author cited the clinical experience of Dr. Robert Newman, of this country, of Dr. Stephenson, of England, and many others, with the treatment of urethral stricture by electrolysis, and showed the inconsistencies and conflict with one another in the theories advanced to account for the claimed results. He also gave the results of the treatment in six cases of stricture at his own hands, and of experiments testing the effect of electrolysis upon animal tissues. He claimed that the experiments demonstrated that the current had no effect in producing absorption in an organic stricture, and that his clinical observations, and analysis of those of others, as far as it could be accurately made from the records, went to prove that the benefit obtained in practice was due to several facts: To its influence on the terminal nerves, overcoming their irritability and consequent muscular spasm; if the stricture were purely spasmodic, the relief thus obtained might be complete; if it were partly spasmodic and partly organic, it could be only partial; the passage of instruments was made easier by the lubricating fluid which the electrical current caused to be thrown out; there was slightly increased rate of exfoliation of hypertrophied epithelial masses; in certain cases there was more or less permanent relief from symptoms of an obscure origin, as frequent and painful micturition. He denied that cases of true organic stricture gradually enlarged by absorption, caused by the electric current, so as to permit the introduction of larger instruments.

Dr. Robert Newman opened the discussion, and said that his own experience had been different from that of the author of the paper. Ten thousand negatives could not contradict one affirmative fact. He quoted from a recent paper by a former skeptic, Mr. Edwards, F.R.C.S., of London, who commenced the treatment on hospital patients with the aid of his friend Dr. Stephenson. Only severe cases had been selected; the location, size, and calibre of the stricture had been given, together with the result of treatment. The only disadvantage attached to electrolysis which this surgeon had found was the time required, while its advantages were many. A permanent cure might follow, which was the rarest occurrence under any other method.

He said Dr. Phelps had undertaken to show that electrolysis overcame only a spasmodic stricture, and did not cure organic stricture; but the truth was that it tended to excite spasm, not to overcome it. Again, no person of experience would confound an organic with a spasmodic stricture. They behaved quite differently. He mentioned the case of a man who had a stricture of small calibre, and a surgeon of much experience failed to pass an instrument at seven consecutive sessions. The patient fell into the hands of a physician in a New Jersey village, who used electrolysis and entered the bladder at the first sitting without difficulty. Dr. Newman said he could not answer a lengthy paper founded on theoretical objections to the method, without preparation, but he did not think it was necessary, for he had advanced facts, and if his explanation of those facts should not prove the correct one it would be of little importance.

Dr. L. B. Bangs said that when the treatment of stricture by electrolysis was first introduced he had hoped it might prove a method by which we could obtain a permanent cure, and without risks. He therefore made some experiments, perhaps less elaborate than those of Dr. Brown, and the conclusions which he had reached were that in some cases he had dilated the stricture, in others he had relieved the spasm, and in still others he had caused condensation of the stricture and rendered the patient's condition worse. Perhaps, however, that was the fault of the technique. Within the past year some patients had come to him who had received treatment by electrolysis, and in some there had been, from the first application of the battery, chordee or retention of urine. He would infer, from Dr. Newman's remarks, that the treatment in those cases had not been properly carried out. In one case there had resulted such condensation of strictured tissue that the patient was in danger of retention of urine. He did not wish to stand in the way of a method which offered such brilliant results as had been pictured by Dr. Newman, yet he was unwilling, personally, to go further with it without more light.

Dr. J. Blake White sent a letter in which he expressed the belief that in proportion to the spasmodic element in the urethral stricture was electrolysis likely to do good. He had reason to doubt whether it had any effect upon organic strictures.

Correspondence.

OUR PARIS LETTER.

(From our Special Correspondent.)

THE RELATIONS OF DIABETES MELLITUS WITH THE ALTERATIONS OF THE PANCREAS—MICROBES IN MINERAL WATERS—GUNSHOT WOUNDS OF THE ABDOMEN.

PARIS, June 25, 1888.

AT a recent meeting of the Academy of Medicine Dr. Lancereaux made an important communication on the relations of diabetes mellitus with the alterations of the pancreas. The eminent physician of La Pitié Hospital had commenced a series of researches more than ten years ago, and he has arrived at the following conclusions: Diabetes mellitus, or glycosuria, such as it is understood in the present day, is not a univocal malady; this denomination serves to express divers morbid forms. Among these forms there is one which, by its sudden appearance, its accentuated symptomatic manifestations, its rapid evolution, and, above all, the emaciation which it determines and the pancreatic lesion which accompanies it, constitutes a definite type. It is this type which the author designates under the name of "diabète maigre" (lean diabetes), or pancreatic diabetes. Besides this type there is another, not less distinct, much more common than the preceding. This, which is essentially hereditary, manifests itself in the first place by *embonpoint*, which generally persists, and is not accompanied by pancreatic lesions. Its symptoms are much less marked than those of lean diabetes, its progress is slow, its duration is undetermined, it is a syndrome which is added to other pathological states, and, for the greater part, to articular chronic manifestations. This he terms fatty or constitutional diabetes. A third type sometimes shows itself after a perturbation of the nervous system, a traumatism, or a severe cerebral shock. It is purely accidental, and is distinguished by symptoms relatively slight, by an evolution and a duration very variable, then by a certain tendency to cure. This traumatic or nervous diabetes is the form the least grave.

Apropos of the pathogeny of diabetes, Dr. Quinquaud read a note at the last meeting of the Société de Biologie on the organic alterations consecutive to neuritis of the nervous vagus. These alterations affect the greater part of the viscera—intestines, pancreas, stomach, liver, kidneys, etc. They are of the same nature as those which are observed in diabetes, and are accompanied by functional troubles which characterize this malady.

At a subsequent meeting of the Academy, Dr. Percepied, of Mont d'Or, read a note on the microbes found in the waters of that station, of which the following are the conclusions: 1. The mineral waters of Mont d'Or contain microbes, some of which are found in an unusual manner in many of the waters non-mineralized. 2. These micro-organisms appear to be the same in all the springs. 3. The number of these microbes appear to diminish according as one approaches the point of emergence of the water, while at the same time their variety diminishes. 4. Experiments have demonstrated that they were not pathogenic.

In a note, at a recent meeting of the Société de Chirurgie, on wounds of the abdomen, Dr. Le Fort remarked that it is of importance to distinguish exactly the spot through which a projectile had penetrated; thus, for instance, wounds of the upper part of the abdomen, and consequently of the stomach, are much less grave. Dr. Bailly, who at Dr. Le Fort's instigation wrote a thesis on this subject, made out that of 88 cases of wounds of the stomach there were 75 cures, and 52 were cured without any intervention. In the other cases the intervention consisted in suturing the stomach. On one occasion, Larrey, the father of the present surgeon of that name, enlarged the incision to evacuate the effusion of blood into the abdomen. For wounds by fire-arms, it is admitted that all the wounds of the abdomen which were cured in these cases were not penetrating wounds. Dr. Le Fort, however, observed that many of these wounds are penetrating, in support of which he cited the experiments of N. Cooper, performed on dead bodies with the blade of a sword of 16 mm. He performed 95 experiments. Of these 95, twenty times the intestine was not wounded, but fourteen times different viscera of the abdomen were wounded. Of the 75 cases in which the intestine was wounded, it was so once in several places. Above the umbilicus the intestine was not wounded in thirty-seven per cent. of the cases; on a level with the umbilicus, in sixteen per cent. of the cases, the intestine was not wounded; below the umbilicus there has always been wound of the intestine. Wounds may be made in the abdomen without the intestine being wounded, particularly above the umbilicus, but in the great majority of cases it is. Care must be taken to distinguish wounds effected by bullets of small calibre from those of large calibre. The obliteration of the wounded intestine with wounds by bullets of small calibre is possible, which makes Dr. Le Fort think that, in these cases, abstention should be the rule. It has been said at that very Société de Chirurgie that, when a bullet had penetrated by the anterior portion, and made its exit by the posterior, this bullet had not traversed the abdomen. Dr. Le Fort's experience could not confirm this assertion, and he did not believe that bullets were so easily deviated. He differed in opinion from Dr. Trélat, who thinks that intervention is necessary in all cases of wounds of the abdomen, whereas Dr. Le Fort asserts that the rule in wounds of the abdomen by bullets of small calibre should be non-intervention. A discussion followed which showed that intervention was necessary only in the cases where it was manifest that the accidents were complicated with lesions, but certain members declared that it was necessary to intervene in all cases, or that at any rate an exploratory laparotomy should be practised. They based their theory on certain considerations: 1, On the gravity of intestinal wounds; 2, on the innocuousness and the efficacy of intervention. No one can contest the gravity of wounds of the intestine; there are, however, observations to prove that these wounds, as well as those of the stomach, get cured spontaneously. With reference to the second point, Dr. Berger observed that intervention would be innocuous only when it is limited to practise an incision, but when exploratory researches are made, the operation becomes much more grave, as they will be made to bear on all the viscera of the abdomen. Dr. Berger concluded that laparotomy should not be altogether rejected, as it alone permits a cure in the cases where complications are developed, but that in the absence of these he would not consider himself justified in intervening.

PURIFIED WOOL-FAT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: Will you allow me to correct a statement which I made on page 517 of your issue for May 12th, that "there is, so far as I am aware, no patent or trade-mark right connected with *lanoline* as a title or as a substance?" I have since ascertained that a patent was obtained in the United States by Otto Braun and Oscar Liebreich, of Berlin, on January 23, 1883 (No. 271,192), for a "Method of Treating Wool-oil to produce Lanolin," and that on July 27, 1886, the following trade-marks were granted:

13,527.—TOILET-SOAP, CREAM, MILK, PASTE, AND POMATUM.—*Benno Jaffé and Darmstædter*, Charlottenburg, near Berlin, Germany. Application filed February 13, 1886. Used since October, 1885.
The word "LANOLINE."

13,528.—SALVES AND PLASTERS.—Benno Jaffé and Darmstædter, Charlottenburg, near Berlin, Germany. Application filed April 23, 1886. Used since October, 1885.
The word "LANOLINE."

The trade-mark "Agnine" is numbered 13,433 and dated June 22, 1886. It therefore precedes the ones issued to the German manufacturers, and thus removes any ground for a presumption that Messrs. Metcalfe & Co. were not acting fairly in the manner of introducing their product.

The fact is that the common name for the fat of sheep's-wool is *suint*. As such it has long been known in the arts. As a medicinal agent it is by no means novel. The "National Dispensatory" (edition of 1886, p. 1662) has the following statement:

> "Pliny says that its uses are numberless, and he describes the manner of procuring it from the wool between the fore-legs and the thighs of the animal by boiling the wool in water and skimming off the floating fat ("Hist. Nat.," xxix., 10). These directions were rehearsed from age to age. In the seventeenth century they were repeated by Culpepper. More recently, according to Strumpf ("Handbuch," i., 128), this fat had a place in the Spanish Pharmacopœia, and uncleansed wool was employed as a dressing for scrofulous and other swellings, and also in gout and rheumatism."

It mitigates, somewhat, my sense of chagrin at having made so erroneous a statement as the one here referred to, to find that the authors of the "National Dispensatory" are, to a certain extent, in the same dilemma in their definition of "Lanolin" (the trade-mark has a final *e*), which, they say, is "the fat prepared from sheep's wool," when, in fact, *lanoline* is the trade-mark of a mixture of purified suint and water, made by a patented process. Their definition would apply much better to *Agnine*, which, according to the manufacturers' statement, contains *no* water; but, to be consistent, the authors of the "Dispensatory" should have used the title "Purified Suint," and *Lanoline*, *Agnine*, or any other form in which it may be offered for sale, should have been treated in the same way that vaseline, cosmoline, and similar trade-mark preparations have been under the general title of "Petrolatum."

Very respectfully,
F. A. CASTLE.

55 EAST FIFTY-SECOND STREET,
NEW YORK, June 15, 1888.

DERMOID CYST OF THE MEDIASTINUM.—At a recent meeting of the Berlin Medical Society, Dr. Loewenmyer brought forward a tumor of this kind, rather larger than a child's head. It was removed from the body of a man who had been shown to the Society four years previously, his symptoms being then difficult to interpret. Apart from hæmoptysis and a moderate degree of pleuritic effusion on the left side, the attention was chiefly drawn at that time to a projection of the left side of the thorax, with loss of resonance, reaching from the clavicle to the sixth rib. The apex-beat could not be felt over the cardiac region, but a thrill was noticed to the right of the sternum, also epigastric pulsation. A precise diagnosis was not made. The patient improved somewhat in hospital, and then went out and worked for a few years regularly, but no symptoms of pressure came on till quite recently, when severe recurring attacks of dyspnœa and cyanosis quickly induced a fatal result. The necropsy revealed a tumor occupying the greater part of the left half of the thorax. Anteriorly it was in contact with the chest-wall, having pushed the heart entirely over to the right. Professor Virchow had examined the tumor, which contained in its interior cysts lined with epithelium and filled with soft substance of gelatinous consistency, but the outer and firmer portion of the tumor was composed of dermoid products, namely, epidermis, hair, fat. Cartilaginous plates were also found. Evidently there had existed abnormality of the chest-wall in the embryonal stage of existence of the patient, so that part of the integument had been displaced inward, and part of the respiratory apparatus outward, at the time of closure of the thorax.—*The British Medical Journal.*

Army News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from June 24 to June 30, 1888.

McPARLIN, T. A., Colonel and Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 52, Department of the Platte, June 20, 1888.

BROWN, J. M. Major and Surgeon. Will take charge of the office and duties of the Medical Director, Department of the Platte, during temporary absence of Colonel McParlin. S. O., 52 Department of the Platte, June 20, 1888.

OWEN, WILLIAM O., Jr., Captain and Assistant Surgeon. Ordered to Fort Leavenworth, Kan., for duty. S. O. 148, A. G. O., June 27, 1888.

. WOODHULL, A. A., Major and Surgeon. Granted leave of absence for three months, to take effect about July 10, 1888. S. O. 148, A. G. O., June 27, 1888.

So much of Par. 3, S. O. 142, A. G. O., June 20, 1888, as relates to Captains GEORGE H. TORNEY and GEORGE McCREERY, Assistant Surgeons, is revoked S. O. 147, A. G. O., June 26, 1888.

WOOD, MARSHAL W., Captain and Assistant Surgeon. Ordered to Fort Randall, D. T., for duty. S. O. 147, A. G. O., June 26, 1888.

SHANNON, WILLIAM C., Captain and Assistant Surgeon. Ordered to Fort Meade, D. T., for duty. S. O. 147, A. G. O., June 26, 1888.

McCREERY, GEORGE, Captain and Assistant Surgeon. Ordered to Fort Warren, Mass., for duty. S. O., 147, A. G. O., June 26, 1888.

JOHNSON, RICHARD W., Captain and Assistant Surgeon. Designated as Medical Officer for a camp of instruction in rifle practice, to be established at Fisher's Island, N. Y. (near New London, Conn.), on July 2, 1888, and to continue during the months of July, August, and September; and ordered to proceed to Fisher's Island in proper season, and report to the commanding officer for duty. S. O. 131, Division of the Atlantic, June, 28, 1888.

GANDY, CHARLES M., First Lieutenant and Assistant Surgeon. Granted leave of absence for three months, to take effect on or after July 5, 1888. S. O. 145, A. G. O., June 23, 1888.

CLENDENIN, PAUL, First Lieutenant and Assistant Surgeon. Leave of absence granted in S. O. 59, Department of Texas, June 4, 1888, extended one month. S. O. 149, A. G. O., June 28, 1888.

CARBOLATE OF MERCURY.—Dr. de Luca has made a number of experiments with the phenate (carbolate) of mercury in the treatment of syphilis (*La Riforma Medica*, May 4, 1888). He gave the remedy in pills of three-tenths of a grain each, from three to six being taken in the twenty-four hours. The results were very good, but no better than would have been obtained with other mercurial preparations, the mode of action of the drug being very similar to that of the tannate. The author does not, however, believe that any useful purpose will be served by retaining this preparation in practice, for it answers no special indication that cannot be better filled by some other salt of mercury. It is difficult to prepare, and it often causes very severe diarrhœa and intestinal pains which necessitate its withdrawal.

Medical Items.

CONTAGIOUS DISEASES—WEEKLY STATEMENT.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 30, 1888:

	Cases.	Deaths.
Typhus fever	0	0
Typhoid fever	9	2
Scarlet fever	149	29
Cerebro-spinal meningitis	4	5
Measles	234	25
Diphtheria	117	35
Small-pox	3	1
Yellow fever	0	0
Cholera	0	0

DEATHS FROM MERCURIAL INUNCTIONS.—Dr. Braus has reported two fatal cases of dysentery following an inordinate use of gray ointment, one patient having consumed over a drachm and the other four and a half drachms each day in inunctions.

A NEW ALKALOID has been extracted by Dr. Domingos Freire from the fruit of a plant indigenous in Brazil, and known to the natives under the name of wolf-fruit. It belongs to the species *Solanum grandiflorum*, and possesses very poisonous properties, its name being derived from the fact, it is stated, that sheep which eat of it die very speedily. The physiological properties of the alkaloid, named by Dr. Freire grandiflorine, have not yet been ascertained.

TREATMENT OF GALL-STONES BY OLIVE-OIL.—Dr. Rosenberg related his experiences in the treatment of gall-stones by olive-oil. A patient suffering from marked biliary colic, that had continued for five years, and had proved refractory in spite of all treatment, including a "Trinkkur" in Carlsbad, and in whom the pain was very acute, was given a dose of 100 grammes of olive-oil (about 3 oz.) at night. In the morning there were found in the stool three concretions, one the size of a grain of linseed, the other two smaller. Some days later a second dose was given of 180 grammes, and in the stool that followed 180 concretions were found, varying in size from a pinhead to a hazel-nut, and after a third dose 243 stones. The patient's troubles soon after this began to diminish, but they did not entirely disappear. She took in all, in five doses, 820 grammes. of olive-oil, and 629 stones were counted in the evacuations that followed. The gall-bladder, which before was the size of the fist, and projected beyond the edge of the liver, diminished so far that it could be no longer palpated. It was assumed that the oil did not act by exciting peristalsis of the intestines, but by passing directly into the gall-bladder and softening the contents. Vomiting only once resulted from the administration.

THE NATURE OF MYXŒDEMA.—The Myxœdema Committee of the Clinical Society of London, Dr. Ord, chairman, has presented the results of its four years of laborious investigation. The report makes a small volume, but their conclusions, which are most interesting, are summed up as follows: 1. That myxœdema is a well-defined disease. 2. That the disease affects women much more frequently than men, and that the subjects are, for the most part, of middle age. 3. That clinical and pathological observations respectively indicate, in a decisive way, that the one condition, common to all cases, is destructive change of the thyroid gland. 4. That the most common form of destructive change of the thyroid gland consists in the substitution of a delicate fibrous tissue for the proper glandular structure. 5. That interstitial development of fibrous tissue is also observed very frequently in the skin and with much less frequency in the viscera, the appearances presented by this tissue being suggestive of an irritative or inflammatory process. 6. That pathological observation, while showing cause for the changes in the skin during life, for the falling off of the hair and the loss of the teeth, for the increased bulk of the body as due to the excess of subcutaneous fat, affords no explanation of the affections of speech, movement, sensation, consciousness, and intellect, which form a large part of the symptoms of the disease. 7. That chemical examination of the comparatively few available cases fails to show the general existence of an excess of mucin in the tissues adequately corresponding to the amount recorded in the first observations, but that this discrepancy may be in part attributed to the fact that tumefaction of the integuments, although generally characteristic of myxœdema, varies considerably throughout the course of the disease, and often disappears shortly before death. 8. That in experiments made upon animals, particularly on monkeys, symptoms resembling, in a very close and remarkable way, those of myxœdema, have followed complete removal of the thyroid gland, performed under antiseptic precautions, and with, as far as could be ascertained, no injury to the adjacent nerves, or to the trachea. 9. That, in such experimental cases, a large excess of mucin has been found to be present in the skin, fibrous tissues, blood, and salivary glands; in particular the parotid gland, normally containing no mucin, has presented that substance in quantities corresponding to what would be ordinarily found in the submaxillary gland. 10. That the full analysis of the results of the removal of the thyroid gland in man demonstrates, in an important proportion of the cases, the fact of the subsequent development of symptoms exactly corresponding with those of myxœdema. 11. That, in no inconsiderable number of cases, the operation has not been followed by such symptoms, the apparent immunity being in many cases probably due to the presence and subsequent development of accessory thyroid glands, or to accidentally incomplete removal, or to insufficiently long observation of the patients after operation. 12. That whereas injury to the trachea, atrophy of the trachea, injury of the recurrent laryngeal nerves, injury of the cervical sympathetic, and endemic influences have been, by various observers, supposed to be the true causes of experimental or of operative myxœdema (cachexia strumipriva), there is, in the first place, no evidence to show that, of the numerous and various surgical operations performed on the neck and throat, involving various organs and tissues, none, save those in which the thyroid gland has been removed, have been followed by the symptoms under consideration; that in many of the operations on men, and in most, if not all, of the experimental operations done by Professor Horsley on monkeys and other animals, the procedure avoided all injury of surrounding parts, and was perfectly aseptic; that myxœdema has followed removal of the thyroid gland in persons neither living in, nor having lived in, localities the seat of endemic cretinism; that, therefore, the positive evidence on this point outweighs vastly the negative, and that it appears strongly proved that myxœdema is frequently produced by the removal, as well as by the pathological destruction, of the thyroid gland. 13. That whereas, according to Clause 2, in myxœdema women are much more numerously affected than men, in the operative form of myxœdema no important difference of the same kind is observed. 14. That a general review of symptoms and pathology leads to the belief that the disease described under the name of myxœdema, as observed in adults, is practically the same disease as that named sporadic cretinism, when affecting children; that myxœdema is probably identical with cachexia strumipriva; and that a very close affinity exists between myxœdema and endemic cretinism. 15. That while these several conditions appear, in the main, to depend on, or to be associated with, destruction or loss of the function of the thyroid gland, the ultimate cause of such destruction or loss is at present not evident.

FORMULÆ FOR RHEUMATISM.—Dr. Chaplin recommends the following for acute rheumatism :

Salicylic acid	℥ ss.
Sodium bicarbonate	℥ x.
Potassium citrate	ʒ jss.
Wine of colchicum seeds	℥ ss.
Simple syrup	℥ j.
Peppermint-water	ad ℥ viij.

Sig. A tablespoonful every three or four hours.

For chronic rheumatism he gives :

Potassium citrate	℥ ss.
Tincture of the chloride of iron	℥ x.
Essence of lemon	ʒ j.
Simple syrup	℥ ij.
Water	ad ℥ iij.

Sig. A teaspoonful every four hours.

A MEDICAL CLUB has been established in St. Petersburg, the objects of which are purely social. Any physician in good standing is eligible to membership, the only dues being the payment of two roubles each evening of meeting. The entertainment consists of music, dancing, card-playing, and tea-drinking. It is hoped shortly to secure a club-house, and then a permanent organization will be effected.

A NEW REMEDY FOR GRAVEL.—Dr. Frochard, writing in the *Gazette des Hôpitaux*, No. 26, 1888, speaks very highly of the leaves of orthosyphon stamineus, a plant growing in the island of Java, in the treatment of gravel and nephritic colic. The natives of Java have long employed the remedy in affections of the kidneys and bladder, using the dried leaves, known in commerce as Java tea. The author has given this tea, and also pills made of one and one-half grain each of the powdered leaves and extract of orthosyphon stamineus, to several patients suffering from gravel, and reports most satisfactory results. After the patients had taken the remedy for a few days the gravel disappeared often for long periods; and if they resumed the drug upon the first symptoms indicating a return of the affection, they were able to keep themselves free from the trouble entirely.

LEFT-HANDEDNESS.—Considerable discussion has arisen of late concerning the causes of left-handedness, some attributing it to education, some to the manner in which the infant is carried in its nurse's arms, and others even regarding it as at times an indication of mental depravity. Dr. Galippe, in a recent memoir, adheres to the theory of heredity as opposed to that of education, asserting that many left-handed individuals have a decidedly neurotic family history. He deplores the fact that all men are not ambidextrous, and looks upon even right-handedness as one of the evils of advanced development. The latter, he says, is the result of atavism; left-handedness, of a morbid heredity.

TREATMENT OF EPIDERMAL HYPERTROPHIES.—Dr. Roesen recommends very highly the following treatment of corns, warts, and other epidermal growths: After moistening the part with some antiseptic solution, boric or salicylic acid, a thick layer (about one-fifth of an inch) of salicylic acid in powder is applied, and retained in place by several layers of lint wet with a boric acid solution, and a piece of gutta-percha tissue. At the end of five days the dressing is removed, when the epidermal thickening will be found to be loosened, the skin underneath being thin, but not broken. If the growth is a very thick one it may be necessary to apply a fresh dressing for a few days longer. —*St. Petersburger Medicinische Wochenschrift.*

CARCINOMA AND SYPHILIS.—Dr. Edward Lang, of Vienna, reports four cases in which cancer and the lesions of syphilis coexisted in the same individual. He believes that the cancer was developed upon a syphilitic foundation, and that the latter is therefore to be regarded as one of the possible, though very rare, exciting causes of carcinoma.—*Wiener Medizinische Blatter*, No. 10, 1888.

PSEUDO-KEPHIR.—The following is recommended as a pleasant drink, and one that is usually retained by the most delicate stomach: Freshly soured milk is thoroughly shaken, and to it is added two per cent. of simple syrup. The milk is then put into a soda-water bottle tightly corked, and set aside to stand in a warm place for three or four days. At the end of this time, on opening the bottle, there is found a foaming and very pleasant-tasting liquid, which contains about two per cent. of alcohol. The milk so prepared is said to taste very much like kephir, whence the name pseudo-kephir has been given to it.

ANTIFEBRIN IN EPILEPSY.—Dr. B. Borosnyói has used antifebrin in a number of cases of epilepsy (*Orvosi Hetilap*), and comes to the conclusion that its value in this affection has been greatly overrated. He found it to be much inferior to potassium bromide. When given in small doses it had no effect, and although in large doses it controlled somewhat the number of the epileptic attacks, it produced such marked cyanosis that it was necessary to discontinue it after a very short trial.

A RETURN TO LATIN.—Dr. Fabriani publishes in *Il Raccoglitore Medico* a letter addressed to the physicians of the whole earth, urging them to return to the mother-tongue of science, the Latin. He thinks that the period at which it was abandoned as a scientific medium of communication is comparatively so recent that there is yet hope of reinstating the language. Unfortunately, Dr. Fabriani has made the mistake of writing his appeal in Latin, so that the letter must remain as a sealed book to most of those into whose hands it may fall, thereby also furnishing one of the strongest arguments against the carrying out of the author's suggestion.

SUPPRESSION OF MEDICAL SOCIETIES IN ALSACE.—The German government has undertaken to suppress some of the Alsacian medical societies, and to change the others in such a way that they shall no longer preserve their French character. It has withdrawn its authorization from the Medical Society of Strasburg, and has ordered the members to hold no more meetings, under pain of two hundred dollars fine and one year's imprisonment. A mutual aid society has been ordered, under penalty of dissolution, to admit German physicians and pharmacists as well as those born in Alsace, and to conduct the business of its meetings henceforth in German instead of in French. Similar measures have been taken against other medical associations formed of Alsacians who prefer the French to the German tongue.

SACCHARINE.—In a communication made to the Paris Academy of Medicine, M. Worms reported some cases in which serious digestive troubles were caused apparently by the administration of saccharine. M. Dujardin-Beaumetz had never seen any bad effects from the use of this substance, but thought it might possibly interfere with the fermentation of alimentary substances during the process of normal digestion. At its present price, however, it might profitably be substituted for sugar in the manufacture of certain alimentary substances, and thus give rise to another form of adulteration against which society would be obliged to protect itself.

ANALGESINE is the new name proposed for antipyrine in France, where it has been learned that the German manufacturers enjoy a monopoly of the name only, and that the drug may be freely made under some other designation.

STRYCHNINE IN DIPHTHERITIC PARALYSIS.—Dr. Gerasimoff reports a case of marked diphtheritic paralysis treated successfully with subcutaneous injections of sulphate of strychnine in the nucha. A perfect cure was obtained within the course of a month, during which the child, six years of age, received a grain and a half of the salt.—*Gaceta Médica Catalana*, May 15, 1888.

REMARKS (I.) ON WHITEHEAD'S OPERATION FOR HÆMORRHOIDS, AND (II.) ON THE SCRAPING OUT OR ERASION OF CARBUNCLE.[1]

BY ROBERT F. WEIR, M.D.,

SURGEON TO THE NEW YORK HOSPITAL, ETC.

I. WHITEHEAD'S OPERATION FOR HÆMORRHOIDS.—Last year,[2] in giving my experience of four months' operative work at the New York Hospital, I reported that after trying Mr. Whitehead's plan of operation for hæmorrhoids I had become dissatisfied with the procedure and had abandoned it in favor of the older and more extensively tried ligation method of Allingham. I beg again to report that after having tried Whitehead's method according to his more recently elaborated plan, I now desire to reverse my judgment, and to speak in favorable terms of the operation.

Mr. Whitehead's first paper on "The Surgical Treatment of Hæmorrhoids" (published in the *British Medical Journal*, February 4, 1882) describes the operation, which he had then practised for nearly five years, somewhat as follows: After stretching thoroughly the sphincter, the hæmorrhoidal masses, involving the whole circumference of the lower bowel, were mapped out into four irregular and unequal lobes. These were divided into four segments by longitudinal sections in the axis of the bowel and in the furrows marking the intervals between the several lobes. This was accomplished without the loss of any blood. Each portion was then grasped in succession by a ring-forceps and dissected with scissors, at first transversely from the anal margin, and then the dissection was continued upward in the cellular plane to the highest limits of the hæmorrhoidal growths, in some cases to a distance of an inch and a half. Each segment was thus converted into a quadrilateral, wedge-shaped mass, the base below consisting of the hæmorrhoid, and the apex above of the healthy mucous membrane of the bowel. The mucous membrane at the highest point was next transversely divided, leaving the hæmorrhoids simply attached by loose cellular tissue, and the vessels proceeding from above and supplying the mass below. The forceps containing the hæmorrhoids was then twisted until this connection was severed, and the hæmorrhoids then removed. The divided surface of mucous membrane was next drawn down and attached by several fine silk sutures to the skin border at the verge of the anus.

The other portions having been treated in the same manner, the operation was completed.

My first series of operations were undertaken after perusal of the above directions. I did not find that it was easy or at all satisfactory to attach the divided mucous membrane to the verge of the anus, and perhaps from my defective appreciation of this operation I did not fairly carry out its details into thorough effect. It was, therefore, not until Mr. Whitehead had published in the *British Medical Journal* of February 26, 1887, an article entitled "Three Hundred Consecutive Cases of Hæmorrhoids cured by Excision," that I learned better how to operate according to his method, which he then more completely detailed in the following words: "After the sphincters have been thoroughly paralyzed by digital stretching, by the use of the scissors and dissecting forceps the mucous membrane is divided a short distance from its junction to the skin, for it is very important," he says, "that no skin should be sacrificed, however redundant it may appear to be.' In this second paper it will also be observed that the quadrilateral section of the hæmorrhoidal masses has been abandoned, and exsection of the lower portion of the rectum is accomplished *en masse*. The further steps of the operation are thus conducted:

The external, and commencement of the internal, sphincters are, after the liberating cut about the anus, exposed by a rapid dissection, and the mucous membrane and attached hæmorrhoids, thus separated from the submucous bed upon which they rested, are pulled bodily down, any divided points of resistance being snipped across, until they are brought below the margin of the skin at the anus. The mucous membrane above the hæmorrhoids is now divided transversely in successive stages, and the free margin of the severed membrane above is attached, as soon as divided, to the free margin of the skin below by a suitable number of sutures. The complete ring of pile-bearing mucous membrane is thus removed in successive snips. The bleeding vessels throughout the operation are twisted when divided. The operation is done as is usual in the lithotomy position. Before the wound is closed iodoform is blown in between the raw surfaces. For the stitches carbolized silk is used. These are not taken out. They are allowed to come away of themselves without further interference. In the three hundred cases reported by Mr. Whitehead not a single death or instance of secondary hemorrhage, or any complication, such as ulceration, abscess, stricture, or incontinence of fæces has occurred.

Since last October I have had occasion to resort to this operation in six severe cases of hæmorrhoids. The first occurred in a man, aged thirty-two, who had had hemorrhage from the rectum, to a greater or less extent, for nearly ten years, with occasional intervals of freedom from this loss of blood. On October 28th an operation according to Whitehead's method (see Figs. 1 and 2) was done, with the removal of nearly three-quarters of an inch of the entire circumference of the rectum, which contained throughout evidences of hæmorrhoidal changes, marked in four places by swellings, which, prior to the removal, were as large as a hickory-nut, and in other parts by numerous varicose veins of varying size. At first there was some difficulty in dissecting up the mucous membrane from the protruding pile, and, in fact, this cannot be done, as the hæmorrhoid involves the mucous and submucous tissues. It is necessary to go somewhat through the pile, looking out carefully for muscular tissue, and keeping to the inside of this until the mucous membrane, recognized by its lighter color, is reached above the pile region. After this latter membrane has been found its separation from the muscular tissues is very easy, only an occasional snip of the scissors being required to detach adhesions, muscular or otherwise. Much less pain was experienced after this operation than is often observed after the operation of ligating piles.

On the eighth day the line of suture was entirely healed. The stitches were not removed, but were allowed to come away of themselves. A week later he was discharged from the hospital perfectly well, with a clean and well-shaped anus, only one or two stitches being still found attached to the skin. These, however, were not troubling the patient. He was seen several months later, and the anus presented a perfectly satisfactory appearance.

---

[1] Read at a meeting of the Practitioners' Society, held May 5, 1888.

[2] A Hospital Experience, etc., New York Medical Journal, Saturday, March 12, 1887.

The second case was met with in a man, aged thirty, whose hæmorrhoidal protrusions occurred one year ago after straining at stool. They have continued at times to bleed. Associated with these was a painful sensation in the rectum. By examination a circle of moderate-sized hæmorrhoids was seen extending all around the lower edge of the rectum, two of which were ulcerated.

On November 5th Whitehead's operation was performed according to the manner above described.

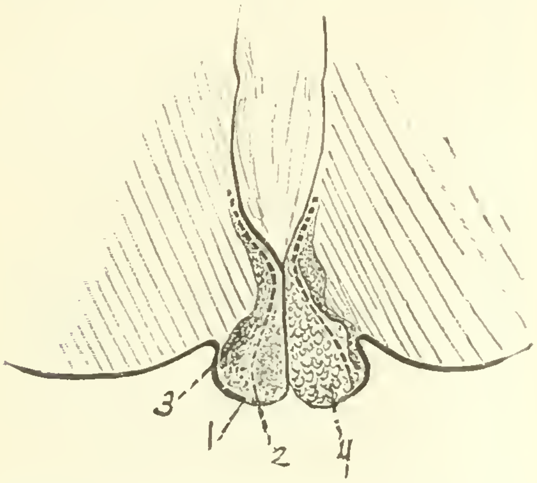

Fig. 1.—1, Muco-cutaneous junction, exaggerated; 2, line of incision, a short distance from muco-cutaneous junction; 3, external sphincter muscle; 4, protruding pile.

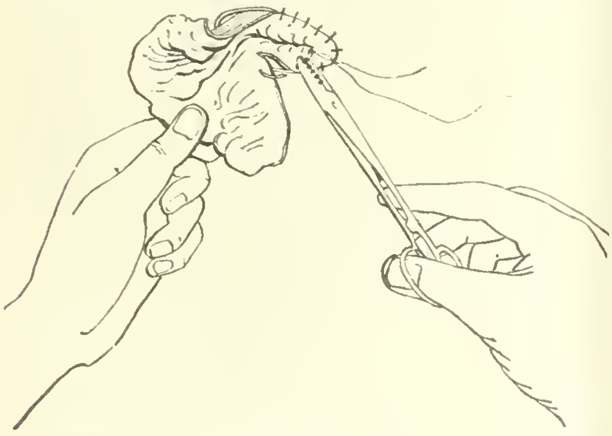

Fig. 2.—Mode of cutting off pile-bearing mucous membrane and stitching it in repeated sections.

Nearly an inch of the rectal mucous membrane was removed. Bleeding vessels to the number of two or three only required to be twisted. The mucous membrane was cut away half an inch at a time, and stitched to the skin by interrupted fine black silk sutures, and so on until the whole circumference of the bowel was removed. The patient progressed to recovery without any special pain or reaction; urination voluntarily accomplished throughout. On the seventh day after the operation the bowels moved without pain, and on the twelfth he was out of bed and walking about. The stitches were removed as the wound was entirely healed, and he was discharged from the hospital on November 23d.

The third case was a man, aged forty-eight, who, in addition to his having hæmorrhoidal swellings of considerable size, just within the sphincter, which protruded and gave rise to frequent hemorrhages, and to a certain amount of pain, had also sensations of uneasiness higher up toward the top of the pelvis, with discharges at stool of rather small tape-like fæces. He complained also of occasional attacks of constipation and colicky pains, with distention of the abdomen, which were relieved by medicine or by spontaneous diarrhœa. Being unable to satisfy myself by digital exploration whether or not a stricture of the rectum somewhat higher up existed, the patient was etherized, and nothing having been felt by palpation in the abdomen, a manual exploration of the rectum was made. By the gradual stretching of the sphincter and of the bowel the hand was introduced up to the knuckles, and slightly beyond them, though the thumb was not passed within the intestine. By this insertion the promontory of the sacrum was recognized, and with the other hand on the abdominal wall nothing was felt in this region. Believing, therefore, to have excluded the suspected stricture, the removal of the hæmorrhoids was undertaken after Whitehead's method. A certain amount of vertical laceration had occurred from the excessive distention of the anus, so that the operative procedure was conducted more after the original plan of Whitehead than after his later procedure. About one inch of the rectum was removed in this way. A longitudinal slit having run up beyond this point, it was sewn together by sutures. Only one suture was required to a bleeding vessel; the others, three in number, were secured by torsion. A plug of iodoform gauze was introduced into the rectum, and an antiseptic compress and bandage applied. The patient suffered a good deal of pain after the operation, and required once to have the urine drawn. The seventh day he had a movement of the bowels, with but little pain. On the eighth day the wound was found to have united primarily, with the exception of an area of one-third of an inch in diameter, which had been caused by a stitch giving way. On the thirteenth day he was up and about. The sutures came away spontaneously.

Case IV.—A man, aged forty-five, had been troubled for several years with bleeding hæmorrhoids of large size. When protruding they resembled in size and appearance a small tomato. The operation was done as in the previous case. Nearly an inch of the lower end of the rectum was removed. The line of junction was effected by more numerous sutures than had been used in the preceding cases. No reaction whatever followed. The patient urinated voluntarily, and no pain was felt. On the third day he was sitting up in bed, writing, and on the sixth day was about. The majority of the sutures were removed by me before the tenth day. Primary union took place, with a very well-shaped anus and smooth bowel beyond the point.

Case V.—A burly, strong man, with large hæmorrhoidal protrusions, bleeding freely, which had lasted for several years. In this instance a departure was made from the ordinary stage of the operation in this, that instead of cutting off the mucous membrane in small segments, and then suturing the same to the skin, the whole circumference of the detached rectum was removed and then the sutures applied. This necessitated the use of clamps to seize and draw down the otherwise retracting mucous membrane, and thereby giving rise by its pressure to a certain amount of damage to the mucous membrane. The procedure, however, rendered a trifle more rapid the operation, which in itself is somewhat a tedious one.

Case VI.—Was a man, aged forty-seven, who had been troubled by large piles coming down and being caught in the sphincter, thereby giving rise to a great deal of annoyance, though not complicated by much bleeding. It was supposed that Allingham's operation might have sufficed for this case. After stretching, however, the sphincter by gradual pressure in various directions, the hæmorrhoidal mass was seen, consisting of three very large piles and one small one, and further, that the whole zone of the rectum was in a varicose condition. Whitehead's operation was thereupon resorted to, and was accomplished with a little more difficulty than usual, from the oozing of blood from the numerous divided veins. This patient was catheterized during the first twenty-four hours, though, I believe, with a little more effort, assisted by the kneeling posture, he could have emptied his bladder without this assistance. The subsequent progress was free from pain. The patient was able to sit up in bed squarely upon the affected part at the end of the third day. He was out of bed and dressed within a week from the operation. The stitches were not removed. They discharged themselves spontaneously.

While for the less severe cases of hæmorrhoids the operation of injection with carbolic acid (and preferably with the 1 to 20 solution) is to be first thought of, and while for the more decided form of this disease Allingham's method yet stands unequalled, yet for the extensive conditions of hæmorrhoidal disease met with in the preceding cases, and which have been hitherto treated by tying off three, four, and sometimes more masses, I believe that greater efficacy and greater permanence of cure will be accomplished by the resort to Whitehead's method, and that less after-discomfort to the patient will be felt than by the well-known method of ligature as practised by Mr. Allingham. It is true, with this rather brief experience, the admission is to be made that the operation of Whitehead has taken me much longer time to accomplish than the older operation of tying and removing hæmorrhoids. Increased experience has, however, taught me that greater rapidity of execution can perhaps be accomplished by a manœuvre which doubtless Mr. Whitehead practises, as it is so self-evident, but which he does not mention. It is this: after separating the mucous membrane at the anus by scissors, all around, then at one limited place conduct the dissection deeper, and in an upward direction, until the normal mucous membrane of the bowel is reached. From that point, by means of the finger nail, or by the end of a blunt-curved scissors, the mucous membrane can be stripped from the external tissues down close to the circumferential initial incision about the anus, when any intervening tissues can be cut through quickly with the scissors. In this way, proceeding right and left, the separation of the bowel in the last two instances has been brought about with decidedly increased rapidity and certainty.

I have been surprised to find how small, after dividing the mucous membrane, the arteries entering the piles become. Palpation of the same through the rectum, prior to their section, had led me to expect them to be of a decidedly increased volume; but with the open section they have not only shown themselves quite small, but they will often spontaneously cease to bleed. It is seldom that they require to be twisted or tied with catgut; certainly not more than one or two in the course of the operation, and these have, in one or two instances, been closed permanently by the pressure of a clamp for a few minutes.

After quite an extensive separation of the rectum, even to some distance above the line of section, it has been found unnecessary to introduce any drainage. In none of my cases have I dusted them with iodoform, as Mr. Whitehead has suggested, and when placed in position prompt union occurred, though the parts were bathed with the usual sublimate solutions—1 to 5,000. The tabs of skin that have been preserved for the final union of their edges to the mucous membrane often remain swollen for a week or ten days after the operation, and may excite some apprehension on the part of the surgeon for the patient that a mass of external reminiscences of the sufferer's past troubles might remain. In three cases where this condition has been watched they have in time disappeared.

As to the possibility of the formation of a stricture, especially where, as in one of my cases, a certain failure of primary union occurred in two spots in the circumference of the wound, I felt some apprehension; especially as this is a condition of affairs that I have encountered a number of times in patients who had been operated upon by surgeons of a past era, by the older method of ligation, so zealously carried out that no mucous membrane was left between the various hæmorrhoidal tied-off bunches. But Mr. Whitehead's positive statement must be kept in mind that this has not been observed in any of his large number of cases. He, however, lays stress upon the necessity of making the primary incision in the mucous membrane near to the skin of the anus, and not in the skin itself, since he believes, and I should think with justice, that undue contractions are more apt to take place when the annular cicatrix is formed at the expense of the integument.

A slight caution I may give, based upon an experience in rectal operations generally, that the bowels should not be moved by any purgative the day of the operation, as is commonly advised. This had better be done the day previously, if at all. Should this error have been brought about, as sometimes it has occurred to me, from a too zealous nurse, it is better to thrust a sponge some distance up the bowel at the beginning of the operation. This preserves the wound from infection, and the surgeon perhaps from profanity.

II. The Erasion of Carbuncles.—Two articles have recently appeared in the *British Medical Journal*, March 24 and 31, 1888, by Mr. Page, Surgeon to St. Mary's Hospital, London, and by Mr. Rushton Parker, of Liverpool, on the subject of the excision and scraping of carbuncles.

The former surgeon presented three cases of carbuncle treated by scraping; and Mr. Parker, so well known to us, reported five cases. The extirpation of the carbuncle was accomplished by the latter surgeon, however, more by excision than by the scraping process. In all these cases the improvement was prompt and marked. But it is my wish rather to speak upon the latter method of treatment than to comment upon other recognized procedures. While it is true, as in the days prior to the use of antiseptics, that the majority of carbuncles do well under the "let-alone" treatment, yet it is fully in accordance with our modern belief in the bacteric origin of such diseases that they should be opened, and, if possible, the irritating masses of germ-laden tissue be removed. Animated with this view I have since 1884, when I first began to resort to this method, so treated five cases of carbuncle which were sufficiently severe to demand surgical interference. They all, save one, occurred in men, and in persons from forty to seventy years of age. They were all situated, except one, on the back part of the neck, the exception occurring between the shoulders. They were also all of considerable size, none in their cribriform area being less than two and one-half inches in diameter, and all were surrounded by the brawny, red swelling which is so often associated with this form of disease. In three of them there was considerable constitutional disturbance; in all there was great pain. The treatment pursued in all the cases was alike and can be briefly described.

An anæsthetic was used in four of the cases; in one cocaine was tried, and succeeded tolerably well, though a great deal of difficulty was experienced in introducing the needle of the hypodermic syringe, on account of the tough character of the skin of the neck, which was rendered apparently much more resistant by the inflammatory process going on. The slough was exposed either by the use of the scalpel or by Volkmann's sharp spoon tearing through the bridge of perforated skin until the yellow infiltrated tissues were reached. The affected parts were scraped out in a very elaborate manner, and their yellow prolongations, which were found in most of the cases to run up under the thick skin, toward the skull, were followed up and scraped out with smaller spoons as far as possible. Whether a mass of such character was found in the skin or among the muscles it was scraped out in like manner. The bleeding is apt to be quite profuse, though easily checked by pressure. After washing out the parts with a sublimate solution (1 to 1,000) the whole cavity, and especially those prolongations referred to above, are carefully packed with strips of a thirty per cent. iodoform gauze, and iodoform freely dusted over. A sublimate dressing is placed over the wound and secured with a four-tailed bandage, two ends of which are wound around the forehead, the other around the neck and under the arms to the back, to secure everything in proper position.

The immediate effect of the treatment is to change nearly at once the character of the pain from that of a burning type to the smarting of an ordinary wound, which speedily passes away, with or without the use of anodynes. The temperature, if previously elevated, also falls, and the other constitutional symptoms ameliorate. At the end of forty-eight hours, or later, according to the amount of discharge, the dressings may be changed, and little sloughs, produced by the tearing process of the operation or by the pre-existent inflammation, will be found to be separated, or in course of separation, and in a few days the wound will assume the character of an ordinary granulating sore.

In one instance I have supplemented this treatment, and with advantage apparently, by injecting into the reddened, inflamed tissue, beyond the reach of my sharp spoon, a solution of 1 to 20 carbolic acid, covering by these injections an area more or less completely surrounding the carbuncle. In this way an equivalent of eight to ten drops of the pure carbolic acid was used without giving rise to any constitutional effect.

It is unnecessary to give in detail the further particulars of the cases of carbuncle cured by me with this mode of treatment. I have only desired to corroborate the good results that have been obtained, particularly by Mr. Page, who has carried out the method more exactly than Mr. Parker, and I believe, with him, that the risks of pyæmia, septicæmia, and exhaustion are very much lessened by this process, as well as being fully convinced that the immediate constitutional effects of pain and fever are promptly checked by this mode of treatment, and that repair is more rapidly established when it is resorted to.

HAY FEVER AS A DISEASE OF CENTRAL NERVOUS ORIGIN,

With a few Cases successfully Treated in accordance with the Hypcthesis set forth.

By B. O. KINNEAR, M.D.,

BOSTON, MASS.

While much has been written upon the causes of this disease, no very satisfactory evidence has been advanced demonstrating the actual factors inducing the acute daily exacerbation; or, considering hay fever as belonging among the neuroses, any acceptable effort made to establish a pathological condition in those groups of nervous cells, or gray matter composing the centres from which the nerves spring, to supply the apparent, but, according to the following view, not real, primary seat of the disease.

The object of this paper is to present an hypothesis in which the effort or attempt is made to show that hay fever, in its immediate symptoms, may be accounted for by an abnormal condition of central nerve-cells.

To begin, let me draw attention to a few recognized natural facts, which will lead up to the ultimate argument.

Grief causes the tears to flow, the muscles of the face to contort, and often a great and rapid failure of muscular strength.

Fear frequently induces tremor of the muscles, a cold surface to the body, and yet a profuse but cold perspiration.

Mental excitement acts immediately, in many, on the secretion of the kidneys, causing a large discharge of urine. Diarrhœa is frequently the result of sudden mental disturbance. Nausea and vomiting are often violent from a disgusting sight or smell. On the contrary, the first results of both joy and anger are to flush the face and invigorate the action of both the mind and body. Lastly, long-continued anxiety produces loss of appetite, a failure of mental powers, and a decrease in the normal nutrition of the whole body.

Here, then, are emotions or psychical causes acting on the brain, or great nervous centre, effecting, through its medium, unusual, and, in most instances, abnormal results, in different parts of the physical economy. The brain can only act upon the physical framework through the nervous system; therefore, it would follow that the resulting abnormal effects must be by the issue of abnormal nervous force.

If this be true, then the brain, through what are understood as natural causes, can give rise to excessive action of glands—as in the lachrymal, tears; the mucous, diarrhœa on sudden shock; fear, the sweat-glands; mental excitement, the kidneys; and the salivary, I may add, at the thought of some delicious dish. Upon the muscular system, in depressant form through fear or shock; in additional strength, by a joyful impression. Upon the arterial system, by a contraction of the blood-vessels, with a cold surface of the body, through fear or shock; an expansion of blood-vessels, from joy or anger; and a failure in general nutrition, with loss of appetite, by anxiety of long duration.

Now, anatomy has demonstrated that almost every nerve may be traced to a group of cells, as its centre, in the spinal cord, the medulla oblongata, or some portion of the gray matter of the brain, before connection is made with the cerebral cortex; while physiology has clearly proven that these centres may act upon distant parts of the body independent of consciousness or of the will-power. If the pneumogastric nerve be stimulated, there is a slowing of the heart's action; if the accelerator nerve of the heart, a more rapid systole and diastole; if the chorda tympani be electrically stimulated, an excessive flow takes place from the submaxillary gland; if the sympathetic nerve supplying this gland be stimulated, the salivary supply from it almost ceases; if the chorda tympani be cut, the discharge almost or quite ceases; and if the sympathetic is severed, increases. If the sympathetic supplying the face be cut, the face flushes, the temperature is raised, and nutrition is increased. If the cut end nearest the face be electrically stimulated, the face becomes pale, nutrition is decreased, and the temperature is lower than normal. When a certain portion of the floor of the fourth ventricle is irritated, diabetes results.

Such illustrations prove that there are automatic centres independent in action of the cerebral cortex, though acted upon by these higher centres under certain conditions.

When these nerve-centres are excited, then, at the terminal ends of the nerves issuing from them we have excited or abnormal action in the distant parts supplied. If nerves to glands, hypersecretion; to blood-vessels, contraction of their muscular coats; to muscles, from the twitching of a muscle to tonic or chronic contraction.

If trophic nerve-centres are involved, skin diseases hypertrophies, and perhaps tumors of various kinds, according to the tissues involved.

If sensory centres, from hyperæsthesia to the most frightful agony may be the result.

Microscopically, cerebro-spinal nerves have been traced directly to the nuclei of the gland cells in the salivary glands by Pflüger[1] and Boll; by Letzench, to the gland cells in the testicle. They have also been traced to the cells in the sweat-glands[2] and kidneys, justifying the view that all glands are innervated in the same manner.

Dr. Klein has traced sympathetic nerve-fibres to the capillary blood-vessels. Drs. Brown-Séquard and Claude Bernard have very conclusively shown that the chief function of the sympathetic nervous system is to regulate the contraction of blood-vessels.

All glands, then, are poised between two forces. The cerebro-spinal nerve-centre being excited, stronger nervous currents flow to the gland cells, which, being stimulated excessively, overcome the contractile force of the sympathetic nerve, the blood-vessels dilate in the gland, and a larger amount of secretion is withdrawn from them (the cells), and discharged through the glandular ducts.

Oppositely, the sympathetic ganglia being stimulated, nervous currents of greater force speed to the nerve-terminals in the muscular coat of the smaller arteries (or the elastic coat of the arterioles?) causing a powerful contraction of the vessels; and, overcoming the normal regulating nerve-current flowing through the cerebro-spinal nerve, ending in the gland cell, the secretion from the gland either ceases or is much diminished.

---

[1] Pflüger: Arch. f. Mik. Anat., Bd. v., S. 193.
[2] Cayne: Compt. Rend., May 20, 1878.

Nerves have also been traced to the skin and connective-tissue cells, adding testimony to the opinion that secretion and nutrition, in all parts of the body, are poised between these two nervous forces, and in health thus normally regulated. In many diseased conditions, either the cerebro-spinal or sympathetic centres are acting with undue energy, thereby destroying the physiological equilibrium. To Dr. John Chapman, of Paris, is the honor of this discovery due, if it be true, as I indeed believe it is.

Having arrived by a process of progressive reasoning to a conclusion which would seem to determine that nervous central excitement induces a changed condition, viz., from health to disease, at the terminal distribution of the nerves, the next point is to demonstrate, if possible, what causes excitement in the automatic nervous centres, and a distribution of more energetic nervous currents, now proceeding in the course of nerves having one function, now another. The answer is, excessive *circulation* in nervous centres, by giving rise to excessive *nutrition*, creates a larger supply of nervous fluid speeding to the nerve-terminals.

If a sensory nerve-centre be hyperæmic, then pain is experienced in the region where the nerves from this centre are distributed.[1]

If glandular centres be hyperæmic, then the glands supplied discharge more freely than in health.[2]

If sympathetic ganglia, then the blood-vessels under their control contract. If muscular nervous centres, contraction of muscles, etc.

Upon the hypothesis that the masses of gray matter composing the roots or centres of the fifth, the glosso-pharyngeal, and the facial nerves, and of some of the cells of the pneumogastric nerves are hyperæmic, and therefore functioning excessively, I have successfully treated several cases of hay fever.

To continue the argument, it is necessary to give the distribution of these nerves to the regions involved in the disease. The ophthalmic branch of the fifth supplies the lachrymal and parotid glands; the facial, the submaxillary gland. It is interesting to observe that while the facial is chiefly a motor nerve in the usual sense, it has motor influence of another kind when its nerves end in the glandular cells, as they do in the submaxillary gland, viz., when excited inducing increased glandular discharge.

In nearly all the ramifications of the fifth to the skin of the face and head and nasal mucous membrane, it is joined, before its final distribution, by filaments from the facial, which would seem to imply from the foregoing that the fifth supplied sensation to these membranes, while the facial terminals were directed to the skin cells, mucous membrane cells, and cells of the mucous glands, regulating nutrition to the skin and mucous membrane, and the discharge from the mucous glands. The third division of the fifth is motor as well as sensory, supplying the parotid gland cells, probably by its motor fibres, and the mucous membrane and glands of the mouth by the same.

The glosso-pharyngeal nerve is sensory-motor, and, with branches from the pneumogastric, supplies sensation as well as nerves of nutrition to the mucous glands and membrane of the pharynx. I say nerves of nutrition, because trophic is the only name which will properly apply to nerves which, when electrically excited, cause an increase of discharge from a gland, as in the case of the chorda tympani, etc.

The sympathetic is now generally recognized as supplying certainly, and probably chiefly, the arterial system.

Anterior and posterior pulmonary branches from the pneumogastric follow all the ramifications of the bronchi.[1]

To fulfil the argument intended, viz., to endeavor to prove that all the immediate symptoms of hay fever may be explained upon the hypothesis that the nervous centres furnishing nerves to the *apparent* seat of the disease are in an abnormal condition, and really, therefore, the primary disease itself, it was necessary to manifest as plainly as possible that the visibly diseased surfaces were supplied by sensory, trophic, and sympathetic nerves. This, I hope, has been done.

The next and most important point is to enumerate the symptoms of the disease, and exhibit, if practicable, how they may be explained without absurdity, upon the hypothesis advanced. In the first place, I consider that there are two forms of hay fever. The first, in which the central cells, composing the roots of the facial, glosso-pharyngeal, and fifth nerves are hyperæmic, giving rise to an excessive discharge from the nasal and pharyngeal mucous membrane, and from the lachrymal gland. The eyes are sensitive to light, and the mucous nasal membrane to the usual irritants, causing sneezing and an acute exacerbation. The skin of the face is not often hyperæsthetic in this form, but is without color, as also the mucous membrane of the mouth and pharynx, on examination, are discovered to be paler than normal, and apparently lacking in a sufficient blood-supply. To the physician's hand the head and face feel cool, the patient is drowsy, and mental action is languid. All of these symptoms denote a strong contraction of blood-vessels in the cerebrum, the head and face, and in the mucous membrane.

There is only a hyperæmia of the lachrymal gland, and the nasal and pharyngeal mucous glandular systems, due to vehement nervous currents speeded from the hyperæmic trophic (?) motor *centres* to the gland cells, overcoming the regulating sympathetic nerve-current and thus dilating the arterioles in the glands, with, as a result, the excessive discharge. If the hypothesis be true, the nervous current flowing to the gland cells must be exceedingly strong, for the evidences as to diminished circulation external to, as well as within, the skull, demonstrate a hyperæmia also of the cervical sympathetic ganglia. There is hyperæmia of the central cells of the fifth, sending sensory nerves to the iris, and to the nasal mucous membrane.

To cure the hyperæsthesia and the mucous discharge, the aim is to drive the blood from the hyperæmic centres, that normal circulation may succeed present congestion within them. This may be done by one of two methods.

If the patient has a feeble general circulation in the extremities, as may be inferred from cold extremities in cool or cold weather, then a Chapman ice-bag, filled with small pieces of ice, applied from the fourth cervical to the second or third lumbar vertebra, two or three times a day, according to the requirements of the case, will cause a dilatation of arterioles throughout the whole body, evenly distributing the circulation, and withdrawing from the excited centres their excess of blood; thus repressing the vehement nervous currents proceeding to the gland cells, with a resulting cessation of the attack.

If the patient gives no evidences of contracted arterioles in the extremities of the body, then a ten-inch ice-bag, used over the cilio-spinal region, will dilate the blood-vessels of the whole head, and thus render the circulation in the previously hyperæmic centres normal.

The first form of hay fever, which might very well be named "contractile," from the general abnormal closure of arteries in the head, with the one exception of those of mucous and lachrymal glandular circulation, is comparatively easily managed by Chapman's system, and may be considered light and uncomplicated when contrasted with the second form, or "expansile," from the general dilatation of blood-vessels throughout the head, face, and brain accompanying the hyperæmia at the roots of the cerebro-spinal nerves mentioned. To arrive at a proper understanding of this assertion in respect to the circulation in the second form of the disease, I will give a list of the principal symptoms connected with the circulation, striving to make it evident that many of them can only be accounted for by the view of a general cephalic and encephalic hyperæmia. In the second form, then, there is often a distinctly hot head over the occipital, vertical, and frontal regions. The face and nose are flushed, and the conjunctivæ injected. There is mental depression, sleeplessness, and blurring of sight; a sense of pressure and fulness and weight in the whole head. The mouth and throat are often dry, and the mucous membrane red and swollen. There is difficulty of breathing and sense of suffocation, independent of the asthmatic attacks, commencing often, however, at the same period as the asthma, about the end of the second or during the third week.

---

[1] Chapman, Dr. John: Neuralgia and Kindred Diseases, page 23.

[2] Chapin, C. V., M.D.: The Sympathetic Nerve, page 20. Vulpian found that irritation of Meckle's ganglion was followed by an increased secretion on the corresponding side of the nose from the nasal mucous membrane.

[1] Gray's Anatomy.

These signs speak for themselves and seem to certainly denote hyperæmia. The difficulty of breathing I am inclined to believe to be due to an extension of the tumidity and redness of the mucous membrane lining the bronchi, occluding partially the air-cells, and so interfering with normal respiration and the oxidation of the blood.

Added to the signs significant of general hyperæmia of the whole head, and therefore *anæmia* of cervical sympathetic ganglia, are those denoting hyperæsthesia of the iris, the skin of the face and cranium, and of the nasal and bronchial mucous membranes; while, lastly, the muscular system becomes directly involved if asthma be owing to contraction of the muscular fibres surrounding the bronchioles supplied by branches from the pneumogastric nerve. I have treated several severe cases of asthma upon this hypothesis, by Dr. Chapman's method, curing some and greatly relieving all but one of those who placed themselves under my care. This patient became discouraged at the end of six weeks' treatment, and stopped the use of the bag against my judgment. He died some months after, in a sudden and violent seizure.

I will further add that the swelling of the dermis of the face, the puffiness and swelling about the eyes, and the swollen and red condition of the naso-pharyngeal and bronchial mucous membranes, together with that of the mouth, would imply, in the views advanced, that trophic-motor cells were hyperæmic in all four of the cerebro-spinal nerve-centres understood to be hyperæmic.

The sneezing and cough involve muscular action, but seem to be, for the most part, reflex. No doubt the sneezing is a powerful and constant factor, producing the general cephalic hyperæmia, and by so continually dilating the arteries gradually renders the sympathetic ganglia *anæmic*, and weakens their contractile power, already weakened by stronger nervous currents flowing along the trophic, sensory, and motor nerves. This fact, if it be one, accounts for a longer seizure each year or two for a certain period, as happens to some individuals, or for a perennial form of the disease, as was the result in one of the cases to be reported.

Hyperæmia of the cerebro-spinal centres as the cause of hay fever also simply and clearly accounts for the severe night attacks, in the small hours of the night, and in the following manner: That "during sleep respiration, oxygenation, and circulation are lessened, while the temperature falls to an appreciable degree," and there is a diminution of circulation in the brain and upon the surface of the body. The blood therefore goes to the internal organs, including the sympathetic ganglia, certainly, if their function is to contract blood-vessels; and, probably, to cerebro-spinal centres as well, particularly if those centres are already hyperæmic through the day. If this be so, then, when the superficial circulation has reached its extreme ebb, which we find to be the case in health at two, three, or four o'clock in the morning, and in exhausting disease at the same hours, at this time the hyperæmia of the centres involved in hay fever will have reached its maximum, and the patient will be awakened by an acute exacerberation of sneezing and discharge, or a severe asthmatic attack. The same reasoning applies to night attacks of simple asthma, neuralgia, or epilepsy, if these diseases are frequently due to nervous central hyperæmia. All the symptoms of this worst and most common form of hay fever can be accounted for upon the hypothesis set forth—hyperæmia at the roots of the nerves supplying the visible seats of the disease; and the successful results obtained by the proper use of the Chapman ice-bag, though few in number thus far, it will be seen, bear witness to the apparent truth of the hypothesis.

The effort, in this virulent form of hay fever, to effect relief or cure, consists in withdrawing the excess of circulation not only from the nervous centres but also in relieving the whole head of its congestion.

This may be done, in most cases, by *gradually* dilating the blood-vessels in the body and lower extremities, thereby allowing the blood to flow in normal amount to this region, thus removing from the hyperæmic head, brain, and centres the superfluity of blood within them. A dilatation of blood-vessels in the legs and feet may be effected by the dorso-lumbar Chapman ice-bag, as I have done over and over again in patients suffering from cold legs and feet; in many cases the parts rapidly become warm, especially if the sufferer be of vigorous constitution. In persons who have been long troubled, or who are of weaker physique, the same results may be obtained, but, of course, more slowly.

The treatment may be accelerated in its action by using ice or ice-water in a rubber-bag, over the base of the brain, expelling from the hyperæmic centres the excess of circulation by the local action of the cold.

According to this hypothesis the sensory centres are hyperæmic, as shown by sensitiveness to light, itching of the skin of the face, the effect of a harsh wind producing a reflex paroxysm, and the frequent and painful paroxysms caused by smoke, dust, ipecac powder, etc., when brought in contact with the nasal mucous membrane, as well as the pollen of plants, and the odors of roses and other flowers. All of the aggravating causes give rise to suffering by reflex action; the impression being carried to the sensory cells, continued to the motor and trophic central cells, and by them reflected to the apparent seat of the disease. Excessively hot days give rise to worse paroxysms, and these I believe to be due to the direct influence of the heat upon the already hyperæmic centres, and upon the already congested brain and head, causing a still further dilatation of blood-vessels, and thus an aggravated expression of the disease.

In persons subject to the disease I believe the originating factor of the hyperæmia of the nervous centres to be summer heat, and that the pollen of plants, smoke, dust, etc., are only aggravating causes, inducing reflex severe attacks.

But whether the heat of summer be the original cause of the disease, the main object to be attained is a successful treatment, unless we can discover and abort, or destroy, the originating cause. If future results of this treatment corroborate the present demonstration, then, so far as treatment is concerned, a remedy has been found which will give relief in almost all cases, and which will abolish the disease in many, if skilfully used by the physician, and faithfully applied by the patient.

The hypothesis advanced seems not unreasonable when we consider that the blood carries nutrition to all parts of the body; that, therefore, the function of any organ may be increased by an increased supply of blood circulating in it. The function of a nervous centre is to supply nervous currents; if, then, this function be increased, it is reasonable to suppose that the centre is hyperæmic, causing more rapid chemical changes, which result in the evolution of an abnormal amount of nervous force.

It is also reasonable because microscopic anatomy traces microscopic nerves to almost all the tissue cells of the body, while physiology assures us that by stimulating nerves with electricity, thus simulating the nervous currents, we may induce active changes in the parts supplied by them.

Once more: it seems reasonable and probable because, by the use of Dr. Chapman's method circulation can certainly be withdrawn from the parts where it is in excess, and sent to regions where it is insufficient.

And, lastly, because it is self-evident to the eye of the physician, when using the dorso-lumbar ice bag of Dr. Chapman, in cases of the second or "expansile" form of the disease, that the excess of blood is being withdrawn from the whole head by the *relief* to all those visible symptoms denoting hyperæmia.

That this paper is crude, and that the evidence adduced is not entirely confirmatory of the views propounded, I am well aware; but feeling that from a small amount of truth a greater may result, I present this hypothesis to the profession, with the following cases in corroboration of the supposition:

CASE I.—Mr. S. G. S——, a gentleman, aged fifty, consulted me in August, 1883. He had been a victim of hay fever thirteen years.

At first he was attacked every August, the disease lasting in severe form until the cool weather commenced. After a few years the seizure did not pass away with the advent of frost, but every ensuing season was later in departure until it had now become perennial. He was comparatively comfortable between midday and midnight, but for three months previous to his consultation with me he had suffered from a violent exacerbation every night. He would suddenly wake at midnight and begin sneezing exceedingly loud and violent. The sneezing was extraordinarily loud and forcible, and the patient correspondingly shaken. It lasted until 2 A.M., at intervals of a few minutes.

There was a tremendous discharge of watery mucus from the nostrils and posterior nares; the latter in such quantity as almost to choke him, and he always soiled from twenty to thirty handkerchiefs. At 2 A.M. the attack would subside, but he would lie awake until morning, and on rising was regularly attacked by cranial neuralgia, which did not cease until noon.

These exhausting seizures, the loss of sleep, and the pain were so seriously affecting his mental powers that he had decided to give up his business if I did not help him.

His complexion was muddy looking, and the skin apparently thickened. The conjunctivæ were constantly red, and the head was abnormally hot all the time. There were semi-unconscious seizures, intense mental depression, and a decided loss of memory, especially in regard to small affairs. The patient was naturally intelligent, and of nervo-sanguine temperament. He had for several years suffered from bilious attacks and constipation. The circulation in the legs and feet was less than normal, and the ventral digestion weak.

He was treated almost entirely by the full-length Chapman ice-bag, viz., from the fourth cervical to the fourth lumbar vertebra. The bag was used three times a day, from one hour to an hour and a half at a time, with the result that the nightly exacerbations almost immediately ceased.

He was only attacked twice after beginning the treatment, although during the first three weeks he would have acute paroxysms, lasting only a few moments, and chiefly in the daytime. The sleep was at once improved, and became quite normal in two weeks. The neuralgia entirely disappeared at the termination of five weeks, and the patient was, both to my observation and his own feelings, practically well. The complexion became clear, the eyes were bright, and the brain recovered its normal action. Memory returned, depression vanished, and the attacks of partial unconsciousness no longer troubled him. The action of the bowels was improved, the bilious attacks became less frequent, and the circulation in the legs and feet normal.

As the patient improved the use of the bag was lessened, and at the end of five weeks he was applying it once a day.

He was advised to continue it once daily for two months more, and then to gradually cease using it.

During the summer of 1884 he was attacked again with the disease. It was immediately checked by the use of the dorso-lumbar ice-bag, and since that time he has remained perfectly free from it. He has continued in business ever since, with no mental trouble to interfere.

This was a remarkably severe case, and in the serious nightly exacerbation during the three months previous to treatment we see a corroboration of the view brought forward in the article that the hyperæmia of the centres involved is probably greatest during the small hours of the night. At the time I treated this gentleman I had not fully worked out the views advanced, and were I to treat another person afflicted in the same manner I should not apply the ice-bag over the cervical region at all, for fear of less rapid relief, owing to its dilating action upon the cerebral blood-vessels when placed over the cervical sympathetic ganglia.

CASE II.—Mr. A. H——, twenty-six years of age, living in Philadelphia, was treated during the summer of 1886. He had suffered for twenty years with a severe type of the second form of the disease. His symptoms were sneezing, much discharge from the nose and eyes, red eyes, red nose, flushed cheeks (especially during an acute paroxysm), hot head, loss of mental activity, and dry mouth. He had attacks of asthma. There was poor appetite, sluggish action of the liver, and constipation; heat and pain in the small of the back, cool legs and feet, and general physical prostration. He was treated by the dorso-lumbar ice-bag of Chapman exclusively, with great relief to all his symptoms, although spending the hot term almost wholly in Philadelphia. He had found great difficulty in former years in regard to brain-work, but passed through the season comfortably in this respect.

The result of the treatment, written by himself in a letter addressed to me, October 21, 1886, will best show what was done:

"It seems to me a great success. When my *liver* was right, I was better than I can remember being at my hay-fever periods; when my liver was *not* in order, I was about as well as I used to be in my *good* days. My sneezing and nose-running, though violent for parts of days, never lasted through whole days, as they used.

"In general I had a large number of days which were much better than I ever had in former years, while my *bad* days this year were about the same as what I used to consider my good ones, with the exception that the reaction in the evening, which I used to have, was not constant this year, and often my evenings were worse than my days. And during all this I was working much harder than I had ever before done during the time.

"It must be said, however, that I was troubled with asthmatic cough and difficulty in breathing about as many nights as is usual."

He was also relieved of the pain and heat in the lumbar region, the legs and feet became warm, the appetite improved, and the physical and mental strength were largely increased. He was advised to continue using the method a short time daily through the winter, and to apply it every summer, as before, in the hope of entirely curing the disease.

The favorable results attained, while the patient was working hard through the heated term and his hay-fever period, show how much more might have been done had he been able to have had rest and recreation in a cooler region during this time. I have not since heard from him.

CASE III.—Miss G. A——, dressmaker, and of exceedingly delicate physique, between thirty and forty years of age, has been more or less of an invalid for ten years, suffering from fainting fits, cold extremities, feeble digestion, constant and severe leucorrhœa, etc. She has been treated during the last five years carefully, by the full length ice-bag, as her symptoms denote only a severe type of the first form mentioned. Her face and head are flushed and hot, but only during a paroxysm of the disease; at other times the head and face are cool, and the skin of the face pale. There is severe itching of the face when attacked acutely. She has been much relieved every summer, and during one comparatively cool season escaped almost wholly. That this patient will quite recover, I believe to be impossible, unless she can retire from her exhausting work for at least two years—exhausting on account of her naturally feeble constitution.

Case IV.—Miss J——, a young lady, living near Boston, consulted me in 1882. She suffered through the whole hot season from the contractile form of the disease, and presented the symptoms as already set forth in the preceding paper. She was treated by cold to the neck alone, that is, over the last four cervical and first four dorsal vertebræ, one hour per day, and in the early morning. She received such benefit through this summer that her suffering was very slight, and since that time, whenever she feels an attack beginning, uses the bag as before, with immediate relief. The disease makes one or two attempts every summer to assert itself, but a few cold applications stop it at once, and this effect is secured independent of heat or the place of residence.

Case V.—In May, 1885, Dr. G—— brought his son to me for treatment, a lad of twelve years of age. For the five previous years he had developed hay fever or rose cold toward the end of May, lasting well into August. He had been taken early each year to Canada, and then to the Franconia Mountains, returning home about August 25th. The patient was brought to me before the disease had developed, but after quite a long investigation by inquiry I decided that the hay fever was a mild type of the severer form, and advised the dorso-lumbar bag, adapted in width to the age of the boy, to be applied to the dorso-lumbar region whenever the attack developed. This was done, and it was not found necessary to take him away from his home during the summer. He has remained almost free from the disease ever since; whenever symptoms were noted the bag was applied, with a complete and immediate cessation of the attack.

Case VI.—I was myself attacked most violently with hay fever in August, 1886, during some very hot weather. I began sneezing steadily and violently, my nose and eyes kept up a constant running; the mouth was dry and hot, and there was intense itching of the eyelids, the skin of the face, and the anterior nasal mucous membrane. The head was not exceedingly hot, and the general health was good, so that it was decided to use the full-length Chapman ice-bag. This was done, with immediate relief. It was applied three times a day, for one hour and a half at a time, for three days, a complete cure resulting. There was no return of the disease last year.

In conclusion, I would say that each case requires a careful examination, not only in respect to the particular form of hay fever to be treated, and the application of the system to secure the most immediately beneficial effect, as well as permanent relief or entire cure; but also, to attain the desired success, the condition of the stomach, the state of action of the liver, and the regularity of the intestinal action must also be inquired into and treated as factors which assist to develop and retain the hyperæmia in the brain and nervous centres. A contracted condition of arterioles in the legs and feet, as shown by cool or cold extremities, also tends to produce congestion in other parts of the body.

I will close in the words of Dr. John Chapman, viz., "The remedial efficacy of the ice is largely dependent upon the care and correctness with which it is applied."

18 Fairfield Street, Boston, June, 1888.

Paris is suffering again, as in most previous summers, from a short water supply.

MALARIAL RETINAL HEMORRHAGE.[1]

BY HENRY DICKSON BRUNT, M.D.,

NEW ORLEANS, LA.

If the question, What effect has the malarial poison upon the eye? were asked, of all the practitioners of our country we of New Orleans should be qualified to make answer. We live in a great city surrounded by low-lying malarial suburbs, the commercial centre of a large area where the disease is endemic. Here stands the Charity Hospital, a great, free, sick-house of three hundred and fifty beds, whither flock the afflicted poor of all the lower Mississippi Valley—the home of the "swamp and rice fevers," of the dusky "bilious remittents," of the fatal "malarial hæmaturias," of the deadly "algid forms"—"congestive chills"—of the pallid "toxæmias," wretched, intractable.

And yet were I to depend upon my own experience I should say that the malarial poison seldom expends its force upon the eye. Indeed the experience of others seems to confirm this view; for though in an excellent paper ("On Eye Affections from Malarial Poisoning") read before the Medical Society of New Jersey, Dr. Charles J. Kipp, of Newark, has brought together instances of the affection of almost every portion of the eye by this poison, these appear to have been for the most part isolated cases occurring in the practice of a limited number of observers of extended experience.

To this one exception must be noted. In a paper read before the American Ophthalmological Society, in 1880, and published in the "Transactions of the Society," Dr. Kipp described for the first time a peculiar superficial keratitis, following and apparently caused by malarial fevers, which, under the best local treatment—the bandage, warm fomentations, and atropia—runs a protracted course, but recovers promptly enough when quinine and arsenic are administered while these applications are made. The observations of Dr. Kipp are confirmed by those of Dr. F. C. Hotz, published in the *Chicago Medical Journal and Examiner* for December, 1881. I have never seen an example of this affection, so far as I am aware. Once I saw extensive sloughing of both corneæ, destroying the left eye, take place during a low, protracted, malarial intermittent. This, however, as is well known, is not uncommon during the course of low fevers.

In the "Transactions of the American Ophthalmological Society" (1882, p. 345, and 1885, p. 64) Dr. W. W. Seeley describes two cases of suddenly occurring and recurring, quickly and completely vanishing, total opacity of the vitreous. These, he thinks, were due to serous effusion into this humor, the effect of malarial poisoning; and a short time ago I saw a similar case, which I am inclined to ascribe to the same cause. My patient lived in a malarial region, and had long suffered, and from time to time still suffered, from chills and fever. Suddenly he noticed decided though slight dimness of vision of his left eye, unaccompanied by any other symptoms. Accurately measured, the vision of this eye was found to be somewhat less than that of its fellow, and examination with the ophthalmoscope, using a plus 16 D glass, showed fine, dust-like opacities of the vitreous. These disappeared completely in twelve days, while the patient was taking sixty grains of iodide of potassium a day, and vision became equal to that of the fellow-eye. All probable causes, save the influence of the malarial poison, could be excluded.

Thus, though I have practised in the centre of a very malarious region, and notwithstanding I have kept watch for these affections, I have seen but one condition of the eye which could without doubt be ascribed to the influence of the malarial poison.

Malarial Retinal Hemorrhage.—The condition seems but little known, and no reference to it can be found in the text-books of Carter (Green, 1876), De Wecker ("Ocular Therapeutics," 1879), Schweiger (1878), Noyes

---

[1] Read before the Louisiana State Medical Society, at its Tenth Annual Meeting, at Monroe, La., April 25, 1888.

(1881), Wells (Bull, 1883), Alt (1884), Swanzy (1884), or Juler (1884). W. R. Gowers refers to it briefly. Dr. Kipp cites Morell Mackenzie (London *Lancet*, October 6, 1877), Kries (V. Gräfe's "Archiv für Ophthalmologie," Band 1., xxiv.), and Karpinsky (*Aertzliche Blätter*, No. 373, 1879; abstract published in Hirschberg's *Centralblat*, March, 1880, p. 84), and says that he himself has seen a number of cases of retinal hemorrhage in patients who had long suffered from malarial fever and were cachectic. The hemorrhages presented nothing characteristic, were small, situated at the periphery of the retina, and caused but slight impairment of vision. Recovery took place, under quinine and ergot, in all cases which could be kept under observation several months. I saw my first case in my clinic at the Charity Hospital, in this city, in the winter of 1882. At that time I was not aware that the condition had ever been noted and described, but the history of the case and a knowledge of the almost identical condition often found in cases of pernicious anæmia made the diagnosis easy. Accounts of this case, and of another which had come under observation, were published in the *New Orleans Medical and Surgical Journal* (December, 1883). Dr. E. W. Jones, of New Orleans, formerly my clinical assistant, and now one of the visiting oculists to the Charity Hospital, whose attention I had called to the matter, published in THE MEDICAL RECORD of June 27, 1885, a short article containing the report of five cases.[1]

Including the two cases which I published in 1883, an examination of the "history books" of the Hospital Eye Clinic shows that six indubitable and two doubtful cases have been recorded during the five years 1882–87.

CASE I.[2]—H. H——, forty-four years of age; laborer. Comes from another ward of the Hospital, November 2, 1882. Large and well-made man, but very anæmic. General health was good until about two months ago, when he had an attack of malarial fever, consisting of five paroxysms (tertian type). Has had no fever for six weeks. A few days ago, "suddenly discovered a dimness to come over sight as though objects were blurred." No pain. Eyes present nothing abnormal on inspection. V. (atropia), R. E. = $\frac{15}{\mathrm{C}}$; L. E. = $\frac{20}{\mathrm{C}}$.

Ophthalmoscopic examination: Media clear; outlines of both discs indistinct—woolly, and there are some fine specks of blood dotted over them. A general view of each fundus shows numerous hemorrhages in the retina. These hemorrhages are situated in every direction, and are of various sizes. In the left eye the most conspicuous one, about two disc diameters square, is about half a diameter below the nerve. In the right eye, the largest one, situated in the region of the yellow spot, is about two diameters square.

November 9th.—Hemorrhages (specks) upon the right disc have disappeared, and its temporal side seems bluer than it was. Absorption is beginning at the centre of the large hemorrhage. Its border presents an unbroken band of dark red, while the centre is buff, mottled with dark brown. There are some shining white points scattered here and there about this central area.

November 13th.—Spleen not much enlarged; might be about 7 × 9 inches, but not more.

November 21st.—V. (without atropia), R. E. = $\frac{20}{\mathrm{C}}$; L. E. = $\frac{20}{\mathrm{L}}$. The papillæ are undoubtedly swollen, and hazy around margins. This is so of right disc, with the exception of a flat and bluish segment at temporal end of the horizontal meridian. All the hemorrhages have decreased in size, and many have disappeared. The large spot near right macula has now assumed a rhomboidal shape; the border is a bright orange-red, the centre stippled with black dots and shining points. The large hemorrhage near the left nerve has a similar border, but the stippling is done in dark red dots on a pale orange ground.

November 26th.—V., R. E. = $\frac{20}{\mathrm{C}}$; L. E. = $\frac{20}{\mathrm{XL}}$ (almost all).

December 4th.—V., R. E. = $\frac{16}{\mathrm{LXX}}$; L. E. = $\frac{20}{\mathrm{XXX}}$. Hemorrhages nearly all gone, especially in left eye.

December 9th.—V., R. E. = $\frac{20}{\mathrm{LXX}}$; L. E. = $\frac{20}{\mathrm{XX}}$ (a few letters). Nearly all the hemorrhages have disappeared. The outlines of the discs are woolly and indistinct.

December 14th.—Pupils dilated with atropia. In the right eye four spots still remain; two small ones are northwest of the disc; the large one at the macula is now about half-a-disc's-breadth wide; toward the nerve it is bordered by a red crescent; for the rest it is composed of black and of shining dots. In the left eye there are two spots; one just below the nerve, about two disc diameters long, is a bright reddish orange color, stippled with pale yellow; the other, a small one, is southwest of the nerve. Both papillæ are woolly, especially the right, which is somewhat bluish at the temporal side.

CASE II.[1]—D. K——, thirty-eight years of age, an Irish laborer, applied at the clinic January 5, 1883. His general health has always been good up to one month ago, when he had a malarial attack. Right eye squints, and he says that he has not seen with it for years. No pain, but the sight of the left eye has become dim. V., R. E. = fingers at six feet; L. E. = $\frac{20}{\mathrm{CC}}$; with + $\frac{1}{30}$s = $\frac{20}{\mathrm{LXX}}$. Nothing abnormal to be noted on inspection. Ophthalmoscopic examination—L. E.: Outlines of disc and details of fundus around it are hazy; the vessels are tortuous; above, and to the nasal side of the disc are two spots of blood overlying the retinal vessels; at the yellow spot is a hemorrhage shaped like a meat-chopper, or the head of an ancient battle-axe (a semilunar figure with a small, roundish projection from the centre of the diameter or chord) the handle (rounded projection) of which covers the fovea.

January 6th.—Right disc and neighboring retina present the same appearances as the left, but I can discover no hemorrhages. In the left eye are three extravasations, which are accurately located to-day—one small one immediately below the nerve, overlying the larger artery and vein as they run downward; another small one on the same vein, lying close along it and scarcely broader than the vein itself, as it runs straight out below the yellow spot; the large meat-chopper-shaped spot at the macula.

January (about the) 10th.—The first of the hemorrhages above mentioned is much smaller; the second has disappeared; the third has lost its "handle" (roundish projection). On the night of January 4th the patient was delirious and bled profusely from the nose during a malarial paroxysm.

CASE III.—J. H——, aged thirty-five, a Swedish laborer, was sent to the clinic December 8, 1883. Had malarial fever last August, and was in bed two weeks. Another attack followed five weeks later, when he was very ill. Once he was delirious all night, and when he woke next morning he discovered that his vision was clouded—there appeared to be a fog before his eyes. At first his eyes gave him a good deal of pain; there is none now, but his vision is worse and the trouble seems to be increasing. He states that he was perfectly healthy and his vision good before these attacks of malaria. Right eye: Outlines of disc sharply defined and somewhat irregular; the disc itself being a bluish-white, decidedly paler than normal, especially on the temporal side, and presenting a deep physiological cup. At the macula is a circular, dark-colored blood-spot, of smooth but sinuous outline, about half-a-disc's breadth in diameter. Exactly in its centre is a bright, white, shining spot. I take it that the hemorrhage is undergoing absorption at its centre, exposing the fovea, and thus giving rise to this appearance. Left eye: Appearance of the papilla much the same as in the right eye; at the macula is a hemorrhage about half the size of the one in the right eye, but lighter in color, and not displaying the central shining spot and stippling. V., R. E. and L. E. = $\frac{20}{C}$.

---

[1] This article directed me to the passage in Gowers above mentioned.

[2] Reported in the New Orleans Medical and Surgical Journal, December, 1883.

[1] Reported in the New Orleans Medical and Surgical Journal, December, 1883.

December 26th.—V., R. E. and L. E. = $\frac{20}{L}$.

Case IV.—R. D——, aged forty, an Irish laborer, was sent to the clinic from Ward 17, April 1, 1884. Has malarial toxæmia; sight is rather dim; no pain of any consequence, though at times he has slight pain across the forehead. L. E.: In the region of the macula is a meat-chopper-shaped hemorrhage, a little over a disc's diameter long and about half as broad. R. E.: There are three small circular hemorrhages in the neighborhood of a rather large artery, near, but not at, the macula, and two small, round extravasations, a little above and to the temporal side of the disc. V., R. E. = $\frac{20}{XX}$; L. E = $\frac{20}{L}$.

Case V.—J. W——, twenty-seven years of age, American, laborer, is suffering from chills and fever; he is very anæmic; his gait is staggering, and his vision has become very obscure.

February 20, 1885.—In the right eye is one large, triangular, thick, smooth-edged hemorrhage, about the diameter of the papilla, situated just at the yellow spot. Several small feathery hemorrhages are scattered about in the neighborhood. L. E.: A small, round, pin-head-sized hemorrhage at the fovea; one or two very small feathery hemorrhages near by. V., R. E. = $\frac{20}{LXX}$; L. E. = $\frac{20}{LX}$.

February 27th.—L. E.: Small hemorrhage at fovea gone. R. E.: The central hemorrhage has diminished in size and become half-moon shaped; the feathery hemorrhages have all disappeared. V., R. E. = $\frac{20}{XXX}$; L. E. = $\frac{20}{XX}$.

March 7th.—L. E.: Papilla swollen and outlines indistinct; several new small hemorrhages on the disk; the vessels are tortuous and the retina cloudy. R. E.: The large hemorrhage at the yellow spot is being absorbed; the fovea shines in this dark blood-spot like a little silver crescent. Patient had a chill two days ago.

Case VI.—C. McK——, an American, iron-worker, aged twenty-nine. "Two weeks ago, during the burning of Colon, the smoke affected his eyes to such an extent that they have not yet recovered." He has suffered severely from malarial fever contracted on the Isthmus, for which he is now in the hospital.

April 13, 1885.—Anæmic. R. E.: Nothing abnormal on inspection. L.E.: There has been perforation of the cornea upward and inward, with the formation of anterior synechia. Pupils dilated. Ophthalmoscopic examination: Each eye presents a large hemorrhage at the region of the macula lutea, and many small hemorrhages scattered about the fundus; the papillæ are pale, and the finer blood-vessels very tortuous. V., R. E. = $\frac{20}{CC}$; L. E. = $\frac{20}{C}$.

April 20th.—Nearly all the small hemorrhages have disappeared; those at the macula have become much smaller.

In the study of these cases the following points are worthy of consideration:

1. Hemorrhage into the retina seems to be a rare effect of the malarial poison. During the years 1882-86 eleven thousand one hundred and ninety-two cases of malarial fever and toxæmia were treated in the wards of the Charity Hospital; but during the same time only six indubitable cases of malarial retinal hemorrhage are recorded in the books of the Eye Clinic. This apparent rarity, however, may be due to the fact that only patients whose vision was much impaired would seek, or be sent to, the Eye Clinic; for Dr. Kipp speaks of several patients whose sight was only slightly impaired by small hemorrhages at the periphery of the retina.

2. All six persons were males, adults, neither very young nor aged. No case of this malady has ever been recorded in the books of the Eye Department for Women and Children. I ascribe their immunity entirely to the fact that they seldom contract, as men often do, by reason of their occupations (wood-cutting, ditching, railroad building, hunting and fishing in swamps), those severe (pernicious) forms of malaria which are prone gravely to derange the blood-producing function, and linger long as malarial toxæmia or cachexia.

3. These six hospital patients were all, of course, in the humbler walks of life. I have never seen a case in private practice, though Dr. Jones and another colleague have. This beyond doubt is due to reasons given under 2.

4. All of my patients were victims of the malarial toxæmia or cachexia, Case V. being a typical example. Referring to his cases Dr. Kipp says: "All of these patients had enlarged spleens, and were of decidedly cachectic appearance." The point is not noted in Dr. Jones' paper. I regret that I have never had an opportunity to examine the eyes of patients suffering from malarial hæmaturia.

5. The hemorrhages are in the retina. The small peripheral hemorrhages are situated in the nerve-fibre layer, as is shown by their being striated or feathery, and lying between the eye of the observer and the retinal vessels. That the large central hemorrhages occupy the deeper layers, we know by their rounded outlines, their dark color, and by the fact that they at times bring out by contrast, at other times obscure, the reflection from the fovea centralis (Case V.).

6. Both eyes are affected in five out of the six cases. We should expect this to be the rule in an ocular affection dependent upon a dyscrasia. It is not improbable that there had been small hemorrhages in the right eye of Case II., which had disappeared at the time of examination. The extravasations being of small size and the eye amblyopic, they would remain unnoticed. However, Dr. Jones states that in several of his cases only one eye was affected.

7. The hemorrhages are commonly multiple. Out of the twelve eyes there were multiple hemorrhages in eight; single hemorrhages in three (none in one). It is to be noted that in eyes presenting but a single hemorrhage this was large and situated at the yellow spot; it seems to me highly probable, especially in considering Case III., that in every case there were other small peripherally situated hemorrhages which were absorbed before the patient came under observation.

8. The onset of the attack is sudden, and, if no complication exists, painless.

9. A slight degree of retinitis, characterized by "woolliness" of the papella, together with haziness of the retina in its neighborhood and tortuosity of the smaller blood-vessels is often observed. This is probably secondary, the result of the violence done the retina by extravasation into its substance.

10. No other parts of the eye are, of necessity, affected.

11. Vision is greatly impaired in all cases in which the hemorrhage is at the macula. In the right eye of Case IV., where the hemorrhages were near, but not at the yellow spot, vision was not at all affected. Drs. Kipp and Jones report cases in which vision was but slightly impaired by multiple peripheral hemorrhages.

12. The tendency is toward recovery, *pari passu*, with the malarial affection, and if the hemorrhages be small, peripheral, and situated in the nerve-fibre layer, recovery is probably prompt and complete; but when extravasation takes place into the deep layers at the yellow spot, recovery is slow, and I doubt if vision is ever perfectly restored. Case I. was watched for forty-three days, but at the end of that time the large hemorrhages were far from being completely absorbed. In the right eye, where the hemorrhage was central, the vision was still seriously impaired; while in the left, where the hemorrhage was near, but not at the fovea, vision had become normal again. Note also vision of the right eye of Case IV. Pallor of the disc, especially of its temporal half, also persists for a long time, and Dr. Jones (*loc. cit.*) describes a case in which the nerve underwent atrophy.

The treatment, of course, is that of the malarial disease; while attacks of chill and fever occur, quinine, arsenic, iron, and strychnine to dispel the cachexia. Perhaps ergot may be useful.

I have had no opportunity to examine, microscopically, eyes containing these hemorrhages, but there is every reason to believe the pathology identical with that of the similar condition in pernicious anæmia. These malarial hemorrhages are due to no special morbid process, but simply to the poverty of the blood induced by the malarial poison. By reason of these blood-changes the capillary walls are ill-nourished and the osmotic currents deranged. Extravasations of blood are seen in the retina in states of anæmia from loss of blood, and "Stephen Mackenzie has pointed out that when the corpuscular richness of the blood falls below fifty per cent., whatever the cause of the anæmia, the tendency to retinal hemorrhage is present" (Swanzy).

NOTE.—May 29, 1888. With De Wecker, we may suppose the light striated hemorrhages to be due to diapedesis; the larger, denser hemorrhages are undoubtedly due to rupture of the finer vessels of the retina, the blood penetrating among the deeper (outer) layers. In an article entitled "Apoplexie générale du Corps vitré chez les Adolescents," in the *Recueil d'Ophthalmologie* for January, 1888, p. 26 *et seq.*, Dr. Ziewinski says that an examination of the blood of his patients showed a diminution of the red in proportion to the white globules (oligocythæmia). He suggests that the presence of an excess of white globules would lead to a blocking by them of the capillaries and subsequent rupture. This phenomenon would explain Mackenzie's observation. We know that whenever the white cells largely exceed in number the red, the former have a tendency to collect along the capillary walls (the local condition in inflammation), and in this position they must further interfere with the nutrition of the walls and the osmotic ebb and flow, and tend to obstruct the blood-current. Perhaps veritable white-cell emboli may be formed, and every condition favoring rupture of the minute vessels and extravasation of their contents be brought about.

NEW ORLEANS, June 13, 1887.

HYPOGASTRIC LITHOTOMY.—At a recent meeting of the Société de Chirurgie Professor Guyon read a paper on the therapeutic value of hypogastric lithotomy, the advantage of which, over the perineal operation, is becoming more and more confirmed. The author divides this operation into several parts: exposure of the subperitoneal region, pushing back of the peritoneum, entrance into the bladder by punctures on account of the presence of the venous plexus engorged with blood. It is when the surgeon has penetrated into the bladder, and when he wishes to act, that it is necessary to fix the organ. To effect this Dr. Guyon suspends and fixes it with two threads running parallel, which serve to keep it open, whence the impossibility of infecting the subperitoneal cellular tissue. The fixation and the suspension are the more necessary at this moment, as the bulging of the rectum produces a deformity of the bladder. The procedure adopted by other surgeons, which consists in not applying sutures, is, according to the author, defective, as these are necessary to prevent the swelling which forms when they are not applied, particularly above and below. As for the tubes, they should always have a fixed and invariable bend. The recti muscles should be sutured, in order to have a firm and deep cicatrice. The partial suture of the bladder with drainage is the practice which is now recommended, as this operation causes a remarkable facility of absorption, so much so that the smallest quantity of carbolic acid or of iodoform produces toxic effects. Consequently Dr. Guyon recommends that antiseptics should be employed but very moderately, asepsis being preferable to antisepsis.

BINIODIDE OF MERCURY IN SURGICAL DRESSINGS.—Dr. Rogée uses the biniodide of mercury in antiseptic dressings, and thinks that it possesses many advantages over other substances employed for the same purpose. It is not irritating to raw surfaces, is a very powerful antiseptic, and is much cheaper than most of the dressings used.

Clinical Department.

PARTIAL CALCIFICATION OF THE MEMBRANA TYMPANI.

By S. MITCHELL, Jr., M.D.,

HORNELLSVILLE, N. Y.

CALCIFIC spots in the membrana tympani are, I think, quite rare. Wilde mentions several cases of this sort, one in particular, in which these spots were seen in the membrane of a patient who became deaf as a consequence of parturition. Pomeroy cites this case, besides several others. The case above referred to bears a striking resemblance to one I now have in charge, and the particulars of which I herewith relate. Mrs. F——, forty years of age, married at the age of thirty-eight. Previous to confinement, three months ago, she had been in good health. There was no history of any previous ear disease. I first saw her May 9th, when she called upon me seeking relief from a constant and distressing tinnitus in the right ear. Her general health was now poor, she was pale and anæmic, the circulation was feeble, and the bowels were constipated. The hearing was as follows: H.D.R. $\frac{2}{60}$, H.D.L. $\frac{25}{60}$, O.C. better in both. By inflation the hearing was increased to $\frac{12}{60}$ in R., there being no improvement in L. The membrane of the left ear presented a dull, lustreless appearance; that of the right ear was normal, except that there was a dense white crescent in the lower and posterior part of the membrane, about two lines broad and four or five long. At my first examination I was unable to account for this appearance of the membrane, but made a diagnosis of chronic catarrh of the left middle ear, and mixed trouble in the right; being somewhat mixed myself by the rather unusual appearance of this membrane. The next day the hearing was H.D.R. $\frac{10}{60}$, H.D.L. $\frac{30}{60}$, which was improved by inflation to $\frac{26}{60}$ in R. and $\frac{40}{60}$ in L., and remains the same at the present time, as also does the tinnitus, which troublesome symptom resists all treatment, and constitutes the whole burden of my patient's complainings. At my second examination, thinking that the unusual appearance of the right membrane might be due to an accumulation of fluid in the tympanum, I determined to puncture the membrane and thus evacuate it of a collection which I suspected was there, causing the tinnitus by pressure on the stapes. I found, to my surprise, when the point of my paracentesis knife came in contact with the membrane, in the centre of the white crescent, that there was a feeling imparted to it as if striking bone. I desisted from any further surgical measures, concluding that the peculiar appearance of the membrane was due to a calcific condition, and doubtless associated with a deposit of the same material in the tympanum, thus explaining the cause of the incurable tinnitus aurium.

HYSTERIA IN THE NEGRO.

By PHILIP S. RAY, M.D.,

WASHINGTON, D. C.

I SUPPOSE no affection of the nervous system has been more variously defined than hysteria. To the physician in every-day practice the affection clinically resolves itself into a functional nerve trouble, the whole nervous system, during the attack, being excessively sensitive, the principal cerebral trouble being a weakening of the will. Hammond tells us that he has been informed that hysteria was almost an unknown disease among negroes during the slave period. I think the observer who informed him must have been mistaken, for we find the most typical cases of hysteria in the negro during religious excitement, and these scenes were certainly common during "slave times." The disease in all its forms is certainly very common now with the negro. Their low form of intelligence and their emotional nature are both favorable to the disease. Hammond says want of work among women is a great cause of hysteria. This may be true in the homes of wealth, but it *oftenest* comes from overwork in those who labor in factories, shops, and private houses. It is essentially, says Suckling, a disease of failing health, worry, and mental strain. The negro woman of to-day attempts to imitate her American white sister in dress, and at the same time do hard work; for they do all the work for the men, particularly in cities. Instead of the negro children being allowed to run (as God intended them) in the open air until they become strong enough to work, they are placed in an unhealthy school where they are made to absorb a little from books, which they do quite rapidly, not taking one idea as regards the real merit of the subject. This is kept up until they are about fifteen years of age, when they are put to work, either at home or in some house, in modern dress. These changes in their mode of life, I think, account for the number of hysterical negro women of this day. The hysteria of men (or neurasthenia, as it is called) comes usually from mental strain, which, of course, does not occur in the negro, so we do not see this trouble in men. I will cite two cases of hysteria, as I found it in the modern negro. I was called, a few days ago, to see a girl twenty years of age. She had been to school until fifteen years of age, and then put at housework with a tight dress on. When I saw her she had been in bed for a week; said she thought while asleep someone had "*stood* on her stomach." Complained of great pain on touching the abdomen or chest, would cry, and then become unconscious for five or ten minutes; thought she was going to die. I told her it was a nervous trouble, and if she would help me she would be well in a few days. I made her get up and dress, and gave her a prescription of bromide and tinct. cannabis indica, also a tonic. In a few days the nervous symptoms passed away, and she was going about; there had been no return of the symptoms.

I saw last week a very similar case, except more severe. All the bad symptoms disappeared under treatment. Hammond also states the disease is almost unknown with the savage nations. This I doubt. Indeed, I think it is certain all classes of beings have what we commonly call hysteria, and I think the lower animals can also have it, due to their cerebral emotions.

1005 Ninth Street.

KING'S POCKET OPERATING AND AMPUTATING CASE.

Dr. E. S. Fowler, of Springfield, Ill., writes: "I desire to call the attention of the profession to this case, which is free from the cumbersome features of the cases in common use, its size being the smallest possible in keeping with completeness and effectiveness. It contains all that is requisite for ordinary amputations, yet can be carried in the pocket. It is 7½ inches long, 2¾ inches wide, and 1 inch thick, and contains one 6½-inch Liston knife with removable handle, one short knife for circular operations, one pair artery forceps, four artery clamps, one tenaculum, serres-fines, one 6½-inch folding saw with adjustable handle that can be set at any angle, the blade being reversible for use in resections, etc., and one suture-carrier and needle-holder. The latter is the most important feature of the case, being so constructed that any of the sutures in ordinary use can be made with it. In one end of the handle are three bobbins, holding forty yards of suture material, and the other end contains the needles and wire. The needles can be placed at any angle. The case, I understand, has recently been adopted by the medical departments of the U. S. Army and Navy, and by the Marine Hospital Service."

SWALLOWING A THERMOMETER.

Dr. M. Singer, of Galveston, Tex., writes: "The account in The Medical Record of the chewing and swallowing of a thermometer by a patient, leads me to report a similar experience in my practice. The patient, a German, who understood but little English, was admitted to the hospital for a fever, not yet diagnosed. As soon as he was seated by his bedside, I introduced the thermometer into his mouth, enjoining him at the same time not to bite or swallow it. Standing in front of my patient I saw the thermometer disappear in his mouth, while at the same time a motion, as of deglutition, was performed by the man. When I recovered from the shock such a sight gave me, I requested my patient to open his mouth. Sure enough the instrument was there no longer, and when I asked the man in German what he had done with the thermometer, he answered that he had understood me to say that he should swallow it, and, of course, he had obeyed orders. I snatched a blanket from the bed and spread it on the floor, then making the man lie flat on his stomach on the bed, with the head hanging down over the edge of it, I told him that unless he wished to die he should introduce his fingers as far down the throat as possible and make one supreme effort to vomit. This was quickly and efficiently done, for in less time than it takes me to relate it, the thermometer was regurgitated, and fell safe and sound on the blanket. I took the precaution of tying a thread to my instrument whenever afterward it became necessary to take the temperature of this or any other such bright-minded patient."

SUDDEN DEATH FROM DISTENTION OF THE STOMACH.

Dr. M. A. Veeder, of Lyons, N. Y., writes: "A case that recently came under the observation of the writer affords an example of sudden death from a cause that is probably quite uncommon. The patient, a woman in middle life, was subject to dyspeptic symptoms, at times suffering greatly from gastralgia. Otherwise her health was good. On the day of her death she was apparently as well as usual, and ate a very hearty dinner. Rising from the table she went into the garden to feed some chickens. In less than three minutes she was found by her husband, who followed her, sitting upon a step, pulseless and dead. At the post-mortem examination, within twenty-four hours, it was found that the stomach was very large, and had been distended, not only by the hearty meal, but also by a considerable volume of gas. The heart was compressed so effectually by the distended stomach that its walls were in contact with each other, and it did not contain more than a few drops of blood. Careful examination failed to reveal any other cause of death than this stoppage of the circulation, which must have been instantaneous and complete."

Persistent Diarrhœa in Locomotor Ataxia.—The diarrhœa which is met with during the progress of locomotor ataxia is of rare occurrence. Charcot, Vulpian, Fournier, and others, have paid some attention to the subject, and a new case is recorded by Dr. Mathieu. The case was that of a man, aged fifty-five, in whom diarrhœa commenced as long ago as 1867, after an attack of cholera. Despite various and numerous methods of treatment, the symptoms had persisted up to the present time. There were six, eight, or ten stools daily, without any pain or tenesmus. The motions were yellowish in color and liquid, and almost free from mucus. This continuous diarrhœa had been a source of great inconvenience to the patient. The diarrhœa had continued for twenty years, and no appreciable change had been noted in its character during the whole of that period. It may be added that the tabetic phenomena exhibited by the patient were quite typical, and were well marked. These were, absence of the patella reflex, anæsthesia of the lower limbs, Romberg's sign, Argyll Robertson pupil, lancinating pains, etc. No treatment had been of any avail. —*Le Progrès Médical.*

Progress of Medical Science.

Hæmoglobinuria in Rheumatism.—At a recent meeting of the Société des Hôpitaux, M. Hayem made a communication on hæmoglobinuria in rheumatism. The patient, a woman, aged thirty-seven, was attacked with rheumatmatism in 1886, and again in 1887. She was then suckling her sixth child. Six days after the second attack came on she entered the hospital. The urine was completely red; there was pain, adynamia, rheumatic œdema in the arms and hands, copious perspiration, rheumatic pneumonia of the right lung, followed by symptoms of pericarditis. The urine, which was scanty at first, became abundant, and the patient recovered. She did not lose her milk, and began to suckle her child again. The urine presented the characteristics of hæmoglobinuria; it contained no red corpuscles, but a large proportion of albumen and white corpuscles. The blood was normal. This case shows that hæmoglobinuria may appear during an attack of acute rheumatism. It differs from hæmaturia in that the urine contains neither red corpuscles nor stroma. Rheumatic nephritis evidently existed in the case described by M. Hayem. The serum of the blood was not modified during the attack of hæmoglobinuria, and the red corpuscles were not dissolved by the urine. M. Hayem ascribes the hæmoglobinuria to the existence of renal mischief. M. Bucquoy cited a case which he had observed twenty years before of paroxysmal hæmoglobinuria *a frigore*. The patient passed black urine when he was out of doors. The urine became normal when he was indoors. The patient was rheumatic, but not albuminuric. At the time paroxysmal hæmoglobinuria *a frigore* was not properly known. M. Hayem observed that such patients must be regarded as suffering from the effects of cold. The renal lesion, which undoubtedly exists, is not persistent; it is only during the attacks of hæmoglobinuria that albumen is observed in the urine. M. Albert Robin cited two cases of hæmoglobinuria. In the first the patient had a genuine attack of acute rheumatism. The urine became red; there were no traces of red corpuscles; there was considerable albuminuria. Symptoms of inflammatory nephritis soon showed themselves. In the second case hæmoglobinuria appeared before rheumatism. In both cases there were unmistakable signs of severe inflammatory nephritis.—*The British Medical Journal.*

The New Test for Free Hydrochloric Acid in the stomach has been shown by MM. Faucher and Paul not to be infallible. They have found that when a hard-boiled egg is used for the the test meal, if the egg is not perfectly fresh the red color will appear upon the addition of phloroglycine-vanilline. This is owing to the presence of a minute quantity of sulphuretted hydrogen. This source of error may, however, be easily avoided by excluding eggs from the test meal.

Anthrarobin as a Substitute for Chrysarobin and Pyrogallic Acid.—Anthrarobin, a substance discovered and described by Professor Liebermann, has been used by Dr. Behrend, of Berlin, as a substitute for chrysarobin. Anthrarobin is a yellowish-white powder, of a rather coarse description. It is soluble in a small quantity of water; also soluble in ten parts of glycerine at a temperature of 100° C. Soluble also in ten parts of alcohol when cold, and in five parts of alcohol when the latter is boiling. When rubbed up with oil it may be easily made into a salve. In the experiments of Dr. Behrend, a ten per cent. salve was used, and occasionally even a twenty per cent. salve, a ten per cent. tincture, and also a ten per cent. solution in glycerine. In all these different forms it was borne remarkably well, no symptoms of inflammation or irritation being caused. The drug was used by Dr. Behrend in those diseases in which the application of chrysarobin could possibly have been attended with good results, and in all such cuticular affections in which chrysarobin is generally used, viz., psoriasis, herpes tonsurans, pityriasis versicolor, and erythrasma. The salve or tincture was well rubbed into the skin, the loose flakes of epidermis having been previously removed. The action was considerably augmented if the affected parts had been previously washed with soap or saponaceous spirits of potash. The action of anthrarobin is slower than that of chrysarobin, but much more intensive, however, than that of pyrogallic acid, which is so often used to replace chrysarobin, and the disagreeable accompanying symptoms of the latter render its use impossible in certain cases.—*Ther. Gazette.*

The Premonitory Signs and Treatment of Hepatic Disease.—Dr. Myrtle makes the following statements on this subject: He has observed an almost constant metallic taste, and with this coppery taste the patients very commonly noticed that their linen was dyed orange color by their urine. A common sensation was an unnatural craving for food, when there should have been no such desire, shortly after a meal. This was so intense that it amounted to gnawing and must be satisfied. Everyone knows how the temper is affected by the state of the liver, but the mental faculty which is most inconvenienced is the memory, as regards matters important and trivial. The last symptom is a sense of weariness and weakness in the muscles of the lower extremities; they feel quite unequal to the most moderate work, and after it ache as if they had been overstrained the day before. As regards treatment, he pins his faith to mercurials, saline purgatives, diet, and warmth. Of all purgatives he prefers natural mineral waters, and while admitting the power and value of many of the foreign springs, after much experience of their use, he can, with perfect good faith, affirm that the strong sulphurous springs and baths of Harrowgate are administered in the great majority of functional disorders of the liver and digestive organs with quite as much success and lasting benefit as are those of any country.—*The Provincial Medical Journal.*

The Therapeutic Uses of Boric Acid.—Dr. Gaucher has put to test the toxic powers of boric acid by administering it to guinea-pigs. To these animals, of the weight of about ten ounces, he gave, daily, fifty centigrammes during fourteen days, without any injurious effects. It is not caustic, is tasteless, colorless, and inodorous. It has been found an efficacious infectious impetigo application, in the form of ointment, after poulticing. In tuberculous ulcerations, also, Gaucher has found this remedy very useful—and has, moreover, employed it with advantage, internally, in phthisis. Boric acid passes rapidly into the urine, and hence is of service in vesical maladies, as chronic cystitis and enlargement of the prostate.—*Provincial Medical Journal.*

Displacement of the Testicle.—At a meeting of the St. Petersburg Society of Russian Practitioners, Professor Popoff showed a unique case of ectopia of the testicle in a patient, aged twenty-four. The scrotum was found to be normally developed, with the right testicle in its usual situation; but the left half of the scrotum was empty, while exactly at the root of the penis there was a swelling of the size of a walnut, covered with normal skin and containing an oval body which measured about four-fifths of the normal testicle, but felt somewhat softer. The patient said the swelling had been there since birth. He had, however, suffered in early childhood from an inguinal hernia, and Professor Popoff thinks it more likely that the displacement of the testicle developed under the influence of the rupture. The man's sexual power was formerly quite normal, but for about six months he had been impotent. Dr. Popoff could find no similar case in medical literature. Professor Wenzeslaw L. Gruber, the great Russian anatomist, who takes special interest in anomalies, considered the case unique.—*The British Medical Journal.*

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHED BY

WM. WOOD & Co., Nos. 56 and 58 Lafayette Place

New York, July 14, 1888.

EXPERIMENTS IN THE STUDY OF FEVER AND OF THE HEAT-REGULATING APPARATUS.

DR. OTTO POSPISCHIL, has made some excellent calorimetrical studies under the direction of Professor William Winternitz, of Vienna. His method consisted in measuring the amount of heat given off from certain parts of the body under various conditions. The apparatus used was a box-shaped calorimeter of 50 c.c. volume, with one of its six sides open, this open side being applied to the part experimented upon.

Over fifty experiments were made under various conditions, and the results are recorded in tabulated form. The author gives the following summary of his work:

1. Exsanguination of an extremity, with stoppage of the circulation, as by Esmarch's bandage, lessens the heat-loss, or expenditure, by about 70.6 per cent.

2. Stoppage of the circulation, with passive hyperæmia, as with a tight bandage, lessens the heat-loss by about 46.2 per cent.

3. Mechanical irritation, as by friction and rubbing of the skin, increases the heat-loss by about ninety-five per cent.

Hence the value of rubbing and friction of the skin in fever with excessive heat-retention.

4. Feeble chemical irritation causes an increase in the heat-expenditure of about forty per cent. Strong chemical irritations, on the other hand, lessen the heat-loss by about eight per cent.

5. Thermic applications which produce cutis anserina lessen the heat-loss by about 44.5 per cent.

6. A warm douche can, by exciting cutis anserina, lessen the heat-loss as much as 38.7 per cent.

7. Moist cold applications can increase the heat-loss up to eighty per cent.

8. Cold shower-baths, followed by bodily rest, cause a slight temporary decrease in heat-expenditure, followed by an increase amounting to about twenty-three per cent.

9. Cold shower-baths, followed by active bodily movement, increase the heat-loss by about 66.6 per cent.

10. Warm shower-baths, followed by resting in a cool apartment, increase the heat-loss about sixteen per cent.

Dr. Pospischil notes that in two cases of typhoid fever the ascent of the fever was followed by a lessening of the heat-expenditure by about 25.4 per cent. This corresponds with Winternitz's view of the great importance of heat-retention as a factor in producing fever-curves.

If one were to look for some practical application of Pospischil's experiments to the present warm season he must find that particular measure which tends to increase the heat-expenditure without at the same time stimulating the heat-generating apparatus. Sufficient data are evidently not furnished us by our experimenter. Cool wet packs and cool douches apparently promise the most, though warm douches followed by rest in a cool room should give satisfactory results.

THE REPORT OF THE GERMAN SURGEONS.

THE report of the German physicians on the case of the late emperor Frederick is a performance altogether childish and unfortunate. Without doing any good to the dead or the living, it starts a personal controversy that will accomplish nothing but the lowering the profession in the eyes of the world.

The documents submitted by Drs. Gerhardt, Bergmann, and Schroetter say in the main only, "I told you so." The idea that Mackenzie removed a healthy piece of the larynx, and that Virchow diagnosticated this as pachydermia laryngis, is incomprehensible.

Dr. Mackenzie has as yet published a brief account only of the case, which may be assumed, however, to outline a more complete report. This report says:

"In my opinion the disease from which the Emperor died was cancer. The morbid process probably commenced in the deepest tissues of the cartilaginous structures of the larynx, and they became affected at a very early date. A small growth, which was present when I first examined the late Emperor, was removed by me by several operations, and all the portions taken away were submitted to Professor Virchow. He was unable to detect in them any evidence of the existence of cancer. Examinations made at the beginning of March by Professor Waldeyer, however, led to the belief that cancer was then present. Whether the disease was originally cancerous, or assumed a malignant character some months after its first appearance, it is impossible to state. The fact that perichondritis and caries of the cartilages played an active and important part in the development of the disease, no doubt largely contributed to make it impossible to form a decided opinion as to its nature till quite a recent date."

GOUT AND TUBERCULOSIS.

IT has frequently been remarked by clinicians that gouty subjects enjoy an apparent immunity from pulmonary phthisis, or, in the rare cases in which they do suffer from tubercular troubles, the latter run a sluggish course, and often seem to die out like a fire which has no fuel to feed upon.

In a communication made to the Lyons Medical Society (*Le Bulletin Médical*, No. 18, 1888) Dr. Humbert Mollière offers an explanation of this fact, which may be accepted as satisfactory, at least until a better one is offered. He has observed, he says, that suppuration is rare in gouty subjects. For example, when ulceration of the skin follows the formation of tophi on the fingers or external ear, the process is a dry one, and not attended with the formation of pus. In patients of a gouty diathesis, who have commencing pulmonary phthisis, the author has also observed that expectoration is very scanty or absent, showing that there is little or no pus formation. It would seem, therefore, that urates and uric acid are antagonistic to the pyogenic micro-organisms.

Now, ordinarily, when the tubercular bacillus attacks the organs of an individual, it opens the way for the microbes of suppuration, which crowd into the open door, and establish the suppurative process which saps the life of the individual. It is to this pus formation that a great part of the evil effects of the tubercular process is to be attributed, and if this is prevented, as it is in gouty patients, the tubercular bacillus has to struggle for an existence, and is not potent for harm.

Such is the explanation offered by M. Mollière of the immunity from tubercular troubles enjoyed by gouty subjects. It is ingenious, and, as far as it goes, satisfactory.

THE CONSEQUENCES OF GONORRHŒA IN WOMEN.

THE list of diseases which are believed to be caused by gonorrhœa in women is as follows: Chronic discharges, metritis and endometritis, salpingitis and pyo-salpingitis, ovaritis, peritonitis, menstrual irregularities, sterility, possibly puerperal septicæmia. This is a formidable list, and it throws a heavy burden of responsibility upon the man who marries while suffering from an uncured, and, perhaps, contagious gleet.

The serious ills which may follow gonorrhœal infection in woman are now being more generally recognized, and especial attention has been recently called to the matter by the work of Dr. Sinclair on "Gonorrhœa in Woman." The old idea, that man is the worst sufferer from the effects of gonorrhœa, cannot be accepted as unreservedly as used to be done.

Fortunately, prophylaxis is possible in many cases. It is admitted that if the gleety discharge contains the gonococcus, it is contagious, and a careful examination of such discharge ought always to be made by the patient before he takes any chances of inflicting suffering upon others. Years of illness, with all its attendant misery, may ensue from the neglect of such precaution.

THE TREATMENT OF BOILS.

AMONG the minor ills that afflict mankind there are few that cause greater discomfort than boils, and not many of which the results of treatment are more unsatisfactory. The poultice and the knife are the two means which have been relied upon chiefly; but while they possibly mitigate and shorten the suffering, they do not effect a cure of the furunculosis. A second boil follows the first, another succeeds that, and the patient becomes worn out in body and mind before his "crop of boils" is harvested.

It has long been known that certain micro-organisms are present in the pus of a furuncle, and it has been assumed by Pasteur and others that the successive eruptions were owing to the transportation of these micro-organisms, through the medium of the blood, to other parts of the body. In a communication made to the Academy of Medicine of Paris (*Revue Générale de Clinique et de Thérapeutique*, No. 10, 1888), Dr. Loewenberg opposes this view of the generalization of tuberculosis and recalls the theory offered by him in a brochure published in 1881. He holds that the multiplication of boils is effected in two distinct ways. In the more grave and fatal cases he believes that the micro-organisms may become diffused through the medium of the circulation, but in the milder cases the process is rather one of auto-inoculation. The staphylococci (of which he recognizes three varieties—aureus, albus, and citreus—as agents in the production of furuncles) escape with the pus and are carried by the fingers or dressings to other portions of the skin, where they penetrate the follicles and give rise to new centres of inflammation. This he regards as the more usual mode of the perpetuation of the disease.

The author's treatment, which, he maintains, has given him entire satisfaction, is based upon this theory of auto-inoculation, and consists in the simple application of antiseptics. The remedy which he uses and prefers is a solution of boric acid in absolute alcohol. This, he claims, will often abort a furuncle, and will, furthermore, prevent a continued formation of boils. Other antiseptics would give the same results, but he prefers the boric acid on account of its freedom from irritating qualities, such as many of the other substances of this class possess.

Dr. Loewenberg insists more particularly upon the use of alcohol, instead of water, as a menstruum, on account of the greater facility with which it penetrates into the follicles, carrying with it the antiseptic substance held in solution. If a "head" has formed on the boil, he opens it with a heated needle or a fine galvano-cautery point, thereby facilitating the entrance of the remedy into the furuncle.

The treatment of boils by the external application of antiseptics is not new. The author himself, has used boric acid for a number of years, and others have employed various mercurial ointments for the same purpose. But in view of the generally unsatisfactory results of the ordinary modes of treatment it would not be amiss to make a more thorough trial of those recent methods in the hope of removing one of the opprobria of medical practice.

THE SIMULATION OF DISEASE BY CHILDREN.

THERE is a good deal of nonsense written and spoken about the innocence of children, their candor, and absence of all simulation. They are innocent, for the most part, simply because they are ignorant, and they are candid, usually, because they see no occasion for deceit. So generally is this poetic idea held that even physicians, who are usually ready to agree with the teacher of old that "all men are liars," are at times led astray by their faith in the innocence of childhood.

Dr. L. Dufestel has recently published a monograph on "The Simulated Diseases of Childhood" (Thèse de Paris, 1888), in which he reviews the already somewhat extensive literature of the subject, and adds several observations of his own.

Simulation of disease, the author maintains, is very common in asylums, schools, and all places where many children are gathered together. Sometimes they feign disease in order to escape from some disagreeable duty, as an excuse for a lesson not learned, or to attract sympathy; at other times they seem to have no special object, but lie apparently for the sake of lying. Dr. Dufestel divides these children into three classes: First, those who feign some simple indisposition with a definite object, and who are otherwise normally constituted; second, children who pretend to be suffering from more complicated diseases, who present, usually, an hereditary history of nervous affections, and who are not well balanced mentally; and third, hysterical malingerers. It is in dealing with the second class of cases that the physician is most liable to be led astray in his diagnosis, and to believe that he has a real malady to contend with. These children, as before stated, have a neuropathic family history, and they have also been badly brought up, their every whim being yielded to by over-indulgent parents.

These precocious malingerers are more often girls than boys, in the proportion of nearly two to one. They are more frequently from eleven to fifteen years of age, though cases are not uncommon in children of more tender years. The author was unable to learn of any recorded instance of simulation in children under four years of age.

In the diagnosis of simulated diseases in children, the author calls attention especially to two points: The physician should be on his guard whenever the little patient's story of his illness is too monotonous. One who is really ill tells a different tale from day to day, his pain and his feelings being modified by passing circumstances. The malingerer, on the other hand, has his story learned by heart, and repeats it always without any modifications. Another thing that should excite suspicion in the physician's mind is the long duration of the simulated malady, and a want of proportion between the physical signs and the degree of pain or discomfort of which the child complains.

The treatment of the little malingerer should consist rather in the treatment of the parents. The physician should not at once announce that the child is shamming, for the only result of such a course will ordinarily be that the child will pass from under his care. But he should so manage the case that the deception will become apparent to the attendants. Then, M. Dufesnel thinks, and probably very justly, when the parents are once persuaded that the child is deceiving them, there will not be much time wasted in completing the cure. Parental discipline is the most potent remedy for infantile malingering.

THE TREATMENT OF HYDROCELE.

After one has had a large number of successes in the management of any particular disease, especially if these occur without a break, he is led to regard the method of treatment employed as one of peculiar value. This is what has induced Dr. C. H. Bedford to publish in the May number of the *Edinburgh Medical Journal* his manner of treatment of hydrocele.

The treatment which he has found almost universally applicable and successful is the tapping and thorough evacuation of the sac, injection of two drachms each of tincture of iodine and water, thorough shaking up of this injection so that all parts of the secreting surface may be brought in contact with the fluid, and the subsequent careful and efficient strapping of the testicle of the affected side, or, if the affection is bilateral, of each testicle separately. The puncture should be closed by cotton-wool, fixed by flexible collodion.

When there coexists a chronic orchitis or epididymitis, no injection should be made, but the tapping should be followed at once by thorough strapping. The latter should be renewed every fourth day, and continued for three weeks or a month. The main point, after the evacuation of the fluid, is the strapping of the testicle. This furnishes support to the part, affording great comfort to the patient, and prevents in great measure the reactionary swelling after an irritating injection has been used.

THE HARMLESSNESS OF LACERATIONS OF THE CERVIX.

It is many years since the views of Dr. Emil Noeggerath upon the malignant influence of gonorrhœa in women were received with scepticism and indifference. Time, or the tide of fashion, has now brought out evidence in a measure justifying his views.

Dr. Noeggerath has recently presented another radical and somewhat startling series of conclusions. This time he has attacked the fetich of the lacerated cervix. Under the tuition of leaders in operative gynecology, it has come about that no doctor can now look at a torn cervix and not be consumed with the holy fire for tailoring the tear. To intimate that such an operation is not useful and imperative is indeed heresy. Dr. Noeggerath, however, lays down the following propositions:

1. Women with uterine disease conceive more easily if the cervix is lacerated than if it is intact. They abort less often in the first condition than in the second.
2. The position of the uterus is not influenced by cervical laceration.
3. The uterine axis is not lengthened by cervical laceration.
4. Erosions and ulcerations are equally frequent in lacerated and in intact cervices.
5. Erosions of the lips are never the direct result of cervical laceration.
6. Diseases of the tissues of the cervix are not more frequent in lacerated than in uninjured cervices.
7. Cervical tears have no influence on the development of uterine disease either as to intensity or frequency.

In his concluding remarks he recommends that lacerations and tears be left alone.

Naturally, such statements draw out a great deal of criticism. Gynecology would be crippled indeed, if its young devotees could not begin by stitching at the neck. Noeggerath bases his conclusions on an examination of one hundred cases of uterine disease, fifty with intact and fifty with lacerated cervices. Several other writers have of late advocated temperance in the matter of sewing up the neck of the womb. The practice of doing the operation as a routine measure after pregnancy is, we believe, abandoned by most gynecologists. The plan of doing trachelorrhaphy as a preventive of possible future disease has still some advocates, but it is unlikely to become popular.

The truth is that there is a vast deal of unwise surgical interference with the uterine organ and its appendages. While Dr. Noeggerath's views may prove to be too radical, they will have, we trust, a good effect in awakening a conservative feeling toward the lacerated womb.

Medical Education in New York.—We are glad to learn, through receipt of the last annual announcement of the College of Physicians and Surgeons of this city, that a three years compulsory course has now been decided upon by the Faculty. A preliminary examination will also be required before matriculation.

News of the Week.

The New York Polyclinic will open a hospital in connection with the college building in October next.

A Sanitary Convention in Canada.—A sanitary convention and meeting of the Executive Association of Health Officers will be held, by invitation of the Mayor and Council, at Lindsay, on Tuesday, Wednesday, and Thursday, August 14, 15, and 16, 1888.

The Eighth Annual Meeting of the Lehigh Valley Medical Association will be held at Paxinosa Inn, near Easton, Pa., on Wednesday, August 15th.

The Thirty-seventh Meeting of the American Association for the Advancement of Science will be held at Cleveland, O., from Wednesday morning, August 15, until Tuesday evening, August 21, 1888.

By a Will lately made, the Boston Medical Library Association will receive a bequest of $10,000 at some future time.

Dr. Hiram Corson.—In honor of his sixtieth year of practice, Dr. Hiram Corson, of Conshohocken, was tendered a reception in the Bellevue Hotel, Philadelphia, June 6, 1888. The doctor is in his eighty-fourth year, and is the oldest living graduate in medicine of the University of Pennsylvania.

General Sheridan's Case has, it is universally admitted, been brilliantly managed by his attending physicians. There is some satisfaction in finding that a case which has been so conspicuously before the public is one that illustrates the resources of our art. Certainly, if it were not for medical skill, including not only careful nursing but the use of powerful drugs, General Sheridan would not have lived so long as he has done.

The Sudden Death of Dr. J. Milner Fothergill is announced. Dr. Fothergill was one of the most popular and prolific medical writers of the present day. He commanded an unusual degree of literary skill, a large amount of practical knowledge, and a deft way of putting things which made his writings always suggestive and interesting. He had a large number of American readers and admirers.

The University of Bologna, on the occasion of the eight hundredth anniversary of its foundation, conferred its honorary degree upon Dr. S. Weir Mitchell, of Philadelphia, and Sir Spencer Wells, of London.

A Dispensary for the Rich.—In the most beautiful part of Madison Avenue is situated a new dispensary, elegant and beautiful, but there is not a poor person within a mile of it, and when it is open they will have to go into another ward to get their first case, just as that very healthy town out West had to go into the next county for a corpse to start a graveyard. It is said that some wealthy lady contributors in the neighborhood of this new dispensary wanted a place to send their servants.—*N. Y. Cor. Courier of Medicine.*

Acute Peritonitis treated by Abdominal Section.—Mr. Lawson Tait reports eight cases of acute suppurative peritonitis, of various origin, treated by laparotomy and drainage. Of these six recovered.

A New Medical Journal, called the *Medical and Surgical Reporter*, published at Toledo, O., reaches us. The editor should at once change the name of his journal to something other than that already borne for so many years by an esteemed Philadelphia contemporary.

The German Surgeons on the Case of the Late Emperor Frederick.—Dr. Gerhardt, acting under the direction of the other German doctors who attended the late Emperor Frederick, has drawn up a report stating that, early in 1887, the German physicians pronounced the disease from which he was suffering to be of a cancerous nature. They decided to open the larynx, and preparations were made to perform the operation on May 20th, when Dr. Mackenzie saw Frederick and declared that the disease was not cancer, and opposed an operation. Dr. Mackenzie removed a portion of the growth, which Professor Virchow examined, but there was no proof that the piece was taken from the actually affected part. Dr. Gerhardt examined Frederick's throat after this piece had been removed, and accused Dr. Mackenzie of removing a piece from the unaffected part of the throat instead of from the diseased part. Dr. Mackenzie replied that it was possible he had done so. The German doctors protested against Dr. Mackenzie's treatment throughout. Dr. Bergmann, in his report on the case, says that as early as May, 1887, he wanted to open the patient's larynx and excise the growth on the left vocal chord. A small operation promised the best results. Of seven such operations which he performed in Berlin, all were successful. There was then no question of the total extirpation of the larynx. The operation would neither have endangered the life of the patient nor would it have destroyed his voice, although it would have left it hoarse. At that time, in an intelligible voice, Frederick said: "Dr. Bergmann, this tumor must be removed. If it cannot be done on the inside, cut from the outside." Everything was ready for the operation, when the plan was vetoed by Dr. Mackenzie, who repeated his assurance that, after a few weeks of his mild treatment, the patient would recover his voice and be able to command the autumn military manœuvres. Dr. Bergmann censures Dr. Mackenzie for defective manipulation of the larynx, for affording no guarantee that he ever reached the growth, and for trying to shift the responsibility upon Professor Virchow. He also blames Dr. Mackenzie for influencing the press through communications about the details of the Emperor's illness. In his report on Emperor Frederick's illness, Dr. Schroetter says that he first examined the patient's throat in November, 1887, and decided that he was suffering from a cancer so far developed as to make it necessary to extirpate the larynx. Dr. Mackenzie, he says, then admitted that the growth looked like a cancer, but Frederick rejected the plan of extirpation because of the risks attaching to it. The German doctors thereupon signed a declaration placing the responsibility of the case upon the physician who overlooked the growth, even contesting its existence till too late. Dr. Mackenzie is reported to say that the report of the German physicians on Emperor Frederick's malady is a tissue of falsehoods, and that any specialist in laryngeal diseases would see that the review of the case is ridiculous. He will make a report himself later.

The Late Dr. C. R. Agnew.—At a meeting of the Medical Board of the New York Foundling Asylum, held on June 1, 1888, the following resolutions were unanimously adopted:

Whereas, In the vicissitudes and uncertainties of life, death comes to call those whose lives are sometimes of the most value, because most useful to their fellow-men. Such was the case in the person of a member of the consulting staff of this asylum, Dr. C. R. Agnew. Dr. Agnew was a man of uncommon ability, and of urbane and accomplished manner, and his life was largely devoted to the performance of good works. He was identified with many of our public charities, either on the Consulting Staff or as one of the Board of Directors or Governors. He was large-minded, and of a varied and rare executive ability, which he exercised freely on all occasions for the public weal. His colleagues deplore his untimely death, when his mind was brightest and his life most active, useful, and fruitful for good. Be it, therefore,

Resolved. That for the sorrow which has befallen his family we offer our respectful condolence and sympathy. As a further token of our esteem and respect, the Secretary is requested to enter as a minute in the records of this Board, this preamble and resolutions.

Resolved, That a copy of these resolutions be sent to his family, and published in The Medical Record and *New York Medical Journal*.

Committee.

The Balbivalier Prize in Medico-chirurgical Science has this year been awarded to Professor Sangalli, of Pavia, for his essay "La Scienza e l' Arte dell' Anatomia Patologica," a work which is said to have involved immense original study and research. The value of the prize is about $1,200.

The Famous "Christian Science" Case at Medford, with the facts of which our readers are familiar, has reached the end which we believe lawyers predicted, and the woman Cornêr, who permitted the death of her daughter and grandchild by neglect, is released. It will be remembered that the woman was arrested on a charge of manslaughter in causing the death of her daughter, Mrs. Lottie A. James, of West Medford, by neglecting to provide proper medical assistance at the time of her confinement, on April 18th. The case was heard before Judge Pettingill, of Malden, who decided that Mrs. Corner was "probably" guilty, and he held her in $5,000 for trial in the Superior Court at Cambridge. Judge Pettingill's decision was not maintained, however, by the grand jury, which has reported "no bill" against Mrs. Corner.—*Boston Medical and Surgical Journal*.

Quack Advertisements in Religious Journals.—The agitation upon the subject of quack advertisements in religious journals was systematically undertaken by The Medical Record several years ago, with the result, we believe, of establishing some decided improvement in many of our religious contemporaries. Recently, the *Medical and Surgical Reporter* has been discussing the subject. It has brought out, among other things, the following curious letter: "Buffalo, N. Y., February 4, 1888. Editor *Medical and Surgical Reporter:* Sir—I beg to differ with you. I consider that religious journals are precisely the ones that should publish these advertisements. This is the proper place for them; religion is nothing but quackery. The class of papers that they should be kept out of is the scientific and free-thought papers, that advocate what is known to be true. There should be nothing but quack advertisements in the religious newspapers. Yours truly. H. L. Green, Editor and Publisher."

The National Conference of Charities and Correction held its fifteenth annual meeting in Buffalo last week. Among the subjects discussed were: "Industrial Training in Juvenile Reformatories;" "The Commitment and Detention and the Treatment and Care of the Insane;" "The Training and Care of the Feeble-minded;" "Reformation as an End in Prison Discipline;" "Charity Organization;" "Immigration;" "Out-door Relief and Hospitals;" "Municipal Charities and Corrections;" "Care and Disposal of Dependent Children."

Unfavorable View of Apostoli's Method of Treating Uterine Affections by Powerful Galvanic Currents.—Dr. Léon Danion, of Paris, an electrician of some experience, has presented to the Académie de Médecine the following conclusions, based, it must be remembered, largely on theoretical and experimental grounds: 1. Numerous and varied experiments on animals have demonstrated that high galvano-caustic intensities determine congestions often of a violent character, frequently followed by inflammation of the organs interested. 2. The clinical results obtained in the treatment of uterine affections confirm in a very distinct manner these experimental electro-chemico-caustic effects. These high intensities may, in this case, determine grave inflammatory phenomena, the issue of which it is impossible to foresee. 3. There does not exist any physiological datum, any empirical result—in a word, absolutely nothing—which would plead in favor of the substitution of high intensities for low and medium intensities, the latter being completely inoffensive; whence it follows that the method of high intensities is not only dangerous, but absolutely useless. 4. The high voltaic intensities (non-caustic) appear inoffensive, but new experiments are necessary to confirm this conclusion.

The Whooping-cough Bacillus of Afanassjew has been shown, by quite good evidence, to be a specific micro-organism. Additional testimony has been recently furnished by Dr. D. G. Ssemtschenko (*St. Petersburger Med. Wochensch.*, 1888, No. 23.). He asserts that this bacterium is found in the sputum from the fourth day of the disease. It increases as the disease progresses, but disappears before the entire disappearance of the cough. Dr. S. thinks that the pneumonia of whooping-cough is of a peculiar type.

The Increase in Deaths from Bright's Disease in Massachusetts is very striking. In 1850 the mortality-rate was 1.1 per 1,000 of total deaths. In 1860 the ratio was 2.9 per 1,000; in 1870, 10.5; in 1880, 19.7; and in 1886, 30.5. The Massachusetts kidney seems to be losing its resistive power.

Cascara Sagrada, in doses of ♏xv. to xx., t.i.d., is said by Dr. H. T. Goodwin to be very effective in rheumatism.—*N. Y. Med. Journal*.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Stated Meeting, May 4, 1888.

GEORGE F. SHRADY, M.D., PRESIDENT, IN THE CHAIR.

DR. BEVERLEY ROBINSON presented a patient with

CHRONIC GOUT,

who also had some symptoms suggestive of arthritis deformans and chronic rheumatism.

The history of the case, furnished by Dr. John S. Wilson, House Physician of Charity Hospital, was as follows: Henry H——, aged forty-nine, born in Switzerland, a cook by occupation. The family history was good, and the patient denied ever having suffered from venereal disease. Six years ago he had acute articular rheumatism in his feet, ankles, knees, and wrists. This troubled him more or less for eighteen months by its frequent recurrence. Three years ago the patient noticed a small nodule on the posterior surface of each ulna, immediately below the olecranon process. These nodules increased in size until at present they are considerably larger than hazel-nuts. When they first appeared they were quite soft, and the overlying integument was red. On several occasions these nodules have broken down and have discharged a pinkish, semi-solid substance, and also serum and blood. After discharging four or five days they would again heal. At the same time there was a similar deposit at the distal phalangeal joint of the right index-finger. This swelling went through the same phases as the nodules at the elbows.

Upon incising the smaller deposits about the elbow, they were seen to contain a pinkish, musty substance, which, the patient stated, was similar to that spontaneously discharged a few years ago. Upon incising one of these smaller tubercles a mucilaginous fluid was ejected with great force—leading one to suspect that the synovial sac may have been opened. When the largest nodules were incised, the substance contained in them was found to be hard and stony, and could not be pressed out.

Three years ago patient noticed that his hands were assuming the characteristic deformity of arthritis deformans. At present there is extension of the right radio-carpal joint; the first phalanx of the right index- and of the right ring-fingers is flexed, the second phalanges of these members are extended, while the distal phalanges are flexed. The fingers are deviated toward the ulnar border of the hand. The left hand was involved at a later date, and the changes are not so extensive nor so characteristic as those in the right hand. There is an enlargement of the base of each of the second phalanges of the left hand. Upon the extensor tendon of the left ring-finger or upon its sheath, there is a small, hard nodule about the size of a small pea. The toes are but slightly involved. Flexion and extension of the hands and fingers are not painful, nor can crepitus be elicited.

There is more or less anchylosis of all the minor joints of the left foot. This member seems to be thickened, and is the seat of *pes planus*. There is a thickening of the fibrous tissues about the first metatarso-phalangeal joint, but there is no deposit here such as is seen about the elbows. No deformity about the ankles. Patient denies having had an attack of acute gout. There is no deposit of urates in his urine, and he has no endocardial trouble. The pain in his ankles is not influenced by atmospheric conditions.

From the above history we see that the patient has had acute and chronic rheumatism, and at present he has symptoms pointing to chronic gout and arthritis deformans.

The deposit removed from the nodules was examined by Dr. Maurice N. Miller, who reported that it consisted of urate of soda almost exclusively. "The major part appears in the form of minute needles, detached and in clusters. I was also able to make out aggregations of these spiculæ resembling very closely the wheat-sheaf masses often found in urinary deposits. The material was of a pasty or clayey nature when removed—as it was—through an opening made by the scalpel, but was examined by myself only after it had become dry. The sheaves would undoubtedly have been more characteristic, had the matter been examined while yet moistened with its own fluid, instead of with water, which I was obliged to add."

DR. A. BRAYTON BALL thought that there was no doubt that the man had gout, but the question was whether he had also rheumatoid arthritis. The occurrence of this deformity of the hand with gout was not, he thought, unusual, and he saw no symptoms present in the case which could not be accounted for on the theory of chronic gout.

DR. C. L. DANA had seen cases of typical rheumatoid arthritis in which deposits were present.

DR. A. H. SMITH remarked that there was in this case an absence of the distinctive enlargement of the ends of the bones seen in rheumatoid arthritis.

DR. PEABODY said that, judging merely by the present symptoms, and not by the previous history, the case would seem to be one of chronic gout.

DR. ROBINSON said that his object in presenting the case was the atypical and confusing nature of the symptoms. He could not conceive that the patient had three distinct morbid conditions in his system, and he had inclined to the opinion that the man was suffering from gout, although he had never seen an exactly similar case. The ulnar deformity of the hands here present was stated in the books to be characteristic of arthritis deformans.

DR. ROBERT F. WEIR then read a paper (see p. 29) on

WHITEHEAD'S OPERATION FOR HÆMORRHOIDS.

DR. JAMES B. HUNTER said that he had performed this operation several times, and had been more than pleased with the results, even when he had done the older operation. He had occasionally had some trouble with hemorrhage, but had used torsion, as Whitehead advises, and had been able to control the bleeding without any difficulty. One great advantage was the absence of pain after the operation. Whitehead uses silk, but the speaker had employed catgut in one case with good results.

DR. A. H. SMITH referred to a palliative method of treating hemorrhoids when the patients refused operation. This was to give an enema daily of water at a temperature of about 115°, and not to allow the bowels to move without this injection. He had found this plan to give great relief in a number of cases.

DR. PEABODY asked whether the reader of the paper was in favor of injections of carbolic acid.

DR. WEIR replied that there were two methods of making these injections. In the first, pure carbolic acid was used, and in the second, a $\frac{1}{20}$ solution. He preferred the latter, using very pure acid, and injecting only a few drops of the $\frac{1}{20}$ solution. The patients are generally able to attend to their business as usual, complaining only of a little soreness. Pyæmia has been known to follow the injection of the pure acid, or of a $\frac{1}{3}$ solution.

DR. HUNTER said that nitrate of silver had been recommended as being painless, but he had seen it employed in one case, and the patient was in agony during the entire night following the operation.

DR. ROBINSON asked whether, in case of a recurrent and rather painful pile, Dr. Weir would inject the tumor or lay it open?

DR. WEIR replied that if a clot of blood were present he would make an incision and remove it. In the case of an internal pile which had prolapsed and become strangulated, he would give the patient ether, stretch the sphincter, and return the tumor. He had never tried repeated slight stretchings. The plan that he preferred was to dilate the anus gradually by moving the finger about in all directions, and then, after a certain amount of dilatation had been effected by this means, to introduce the thumbs and stretch the sphincter fully. In reply to a question by Dr. Smith, whether he had ever seen any bad results from severe stretching, the thumbs being separated so as to touch the tuber ischii on each side, he said that he had seen incontinence so produced. As regards Whitehead's operation, another advantage that it possessed was, that it seldom gives rise to any bladder symptoms, such as are occasionally seen after other operations.

Dr. Weir also read a second paper (see p.31) on the

TREATMENT OF CARBUNCLES BY SCRAPING OUT.

Dr. Hunter had tried injections of carbolic acid in the treatment of carbuncle, but had not met with any great success.

Dr. Smith referred to a case which had been treated in the manner described by Dr. Weir, in which the results were excellent. He had seen a carbuncle cured by injections of pure carbolic acid. The operation was done by Dr. Chappelle, who had seen the method used in England. A glass pipette was passed into the small openings in the carbuncle and a few drops were allowed to fall into each one.

Dr. Weir thought that the sloughs would prevent any extensive action of the carbolic acid in such a case. Russian surgeons were now treating malignant pustule by corrosive sublimate in powder. A large quantity (several grams) was strewn over the tumor. Here there is a more acute process, and there is not so much sloughing tissue present as in the case of a carbuncle.

Dr. Kinnicutt presented a communication on the

METHODS OF TESTING THE STOMACH-ACIDS,

with a practical demonstration.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN OBSTETRICS AND GYNECOLOGY.

Stated Meeting, May 24, 1888.

Charles Jewett, M.D., in the Chair.

A new needle-holder, devised by Dr. H. T. Hanks, was presented in his absence by Dr. George E. Abbott. It was suitable for holding either the Hagedorn or the straight-needle.

DEMONSTRATION OF MR. TAIT'S METHOD OF FLAP SPLITTING.

Dr. H. T. Hanks sent the paper, which was read by Dr. Abbott. The patient being placed in the Sims position, he proceeded to repair the vesico-vaginal fistula by enlarging the lower angle of the fistula, cutting down fully one-third of an inch to the bladder tissue, then at the farther angle he dissected with the scissors the mucous membrane of the vagina away from the vesical wall one-fourth to one-third of an inch entirely around the whole fistula. Then with his finger-nail he separated the tissues, going over the same locality he had already cut up with the scissors, making sure by the sense of touch that the tissues were evenly separated and dissected up all around the opening. He then inserted a Peaslee needle at the lower angle of the fistula, carefully passed it around in a direction toward the upper angle, and, by the feeling of the finger, making sure that it passed deep in the tissue beyond the angle of the flap. He never allowed the point of the needle to pierce the bladder or vaginal wall. This was done entirely by the sense of touch. The needle was brought out at the upper angle. He then threaded it and withdrew to the lower angle of the fistula, and went over the opposite side in exactly the same manner, pushing the needle to the upper angle, there attached the wire, and pulled it down through on the other side of the tissue, thus making a bag string. He then pushed down the mucous membrane of the vesical wall, drew up the wire, and twisted it. Thus the denuded surfaces were brought together in the vagina, and the vesical part of the fistula was puckered in the bladder, so that what had been the weakest place had become the strongest.

In umbilical hernia the operation was the same, except that the tissue to be manipulated was different. If by accident the peritoneum were pierced, it was only necessary to use the antiseptics and precautions employed in laparotomy.

In lacerations of the sphincter and perineum the operation was essentially the same. Dr. Hanks believed it was impossible, by Mr. Tait's method, to make a large perineum which would exactly correspond with the original tissue torn, but, so far as the sphincter itself was concerned, it was left stronger and better than by any other method.

Dr. Buckmaster had never seen the operation done, but he had from the first looked upon it as dangerous, and this belief had been confirmed by the death of one of Dr. Mundé's patients.

Dr. Jones said some incredulity had been expressed with regard to the statement that Mr. Tait performed the operation on vesico-vaginal fistula entirely by the sense of touch. Having been an eye-witness of the operation, he could testify that it was done by the sense of touch alone. He used the Sims speculum in the Sims position.

The speculum was removed when he came to pass the suture, consisting of silver wire threaded on a tubular needle. Dr. Hanks had described only the purse-string suture. This Mr. Tait used only in small fistulæ. In larger fistulæ the flap was split in the same way but the suture was passed from side to side in the long axis as in the perineal operation. In the perineal operation the flap was split as described, following the line of cicatrix, extending from the inferior margin of the labia minora on each side around the recto-vaginal septum. The tissues were separated and brought together by from three to four sutures of silk-worm gut.

A PLEA FOR THE PRIMARY OPERATION ON THE PERINEUM.

Dr. Hanks' second paper, bearing this title, was read by Dr. Goffe. After twenty years' experience as an obstetrician and fifteen years as a gynecologist, Dr. Hanks had finally become convinced that it was utterly impossible to prevent laceration of the perineum in all cases. He thought that in ten per cent. at least of all primiparæ the laceration took place. The liability to sepsis and a tedious convalescence, with serious after-results if the rupture were not repaired at once, were pictured.

Speaking of the technique of the operation, he said the patient should be brought to the edge of the bed, lying across it on a rubber cloth arranged to drain into a bucket on the floor. An assistant should be at each knee. Irrigation by a weak bichloride solution should be continued ten or fifteen minutes. The knees should not be kept flexed all the time, thus avoiding engorgement of the tissues with blood. The fewest instruments with which one could do the operation were a pair of pocket scissors, a long, slender, but strong Peaslee needle, with a Hagedorn point, devised by himself, was preferred; a suitable thread, as of a silkworm gut, horse-hair, or silver wire. A few whiffs of chloroform should be given, although a local application of cocaine might deaden sensibility. After a thorough douching, the limbs should be straightened and again flexed; a towel should be wrung out of hot water and pressed against the perineum fully five minutes to thoroughly unload the capillaries. A tampon was placed in the vagina to prevent blood running over the wound. Then, under as strong a light as could be obtained, a thorough examination was made to ascertain the exact character of the laceration. The sutures were then passed, three being usually sufficient. The great necessity was to insert the sutures sufficiently deep to hold the parts. He dusted the parts with iode, or other antiseptic; the tampon was removed, a bichloride pad was applied and renewed every two hours; the knees were kept together; the urine was drawn every five hours; the dressing was removed the second day.

It was possible for cases to occur in which the patient was too exhausted to justify the operation; but, as a rule, it should be performed, as it was easily done, and could be done quickly. He thought, with our present knowledge of sepsis and germicides, the dangers of the operation were reduced to a minimum. No septic material need ever be left in the wound when the sutures were tightened. The use of catgut or silkworm gut did away with the pain which formerly constituted an objection to silver wire. Dr. Hanks thought the operation rendered the patient far better able to go through the puerperal state.

Dr. R. A. Murray fully agreed with the author of the paper regarding the importance of the primary operation on the perineum, and he thought the method of operating had been graphically described. He did not approve of so prolonged irrigation of the wound either with the bichloride or carbolic-acid solution. If the injection were kept up fifteen minutes, there would probably be marked relaxation of the uterus, interfering with the operation. If there was anything to render the condition of the parturient woman a serious one, it was a laceration of the perineum over which the lochia were constantly flowing. In the Maternity Hospital, the rule had been in force at least the past four years to repair all lacerated perinei at once. If there was but the slightest tear, they inserted only one suture. If the rupture was in the second degree, the operation was made thorough. He thought we made too light of laceration of the perineum as a factor in the production of subinvolution. Probably the physician too often left the case, intending to operate the next morning, when it became impossible because of the swollen condition of the tissues, etc., and then puerperal diphtheria developed. He thought the primary operation was not oftener unsuccessful than the secondary when performed by the same hands. He did not think laceration took place in ten per cent. of primiparæ. He thought the Goodell method of lifting the child's head forward during delivery would do much to prevent rupture. Regarding Dr. Hanks's preference for the Hagedorn needle, he had found the shank too thick, leaving a hole not completely filled by the suture, and which did not heal readily. An ordinary needle would do. He used silver wire. One reason why the operation was less frequently successful than it should be was failure to place the anterior suture far enough forward. It should be placed on a line with the tear.

Dr. H. J. Garrigues had been accustomed to repair at once the lacerated perineum during the past twelve years, and he had observed that in this country the leaders in the profession had come generally to express themselves in favor of the operation. He further emphasized the objection made by Dr. Murray to using the intrauterine douche ten or fifteen minutes, whether bichloride or carbolized solution were employed. He had been induced, by the report of fatal cases, to reduce the strength of the bichloride solution to one in four thousand, and he thought it might be even still weaker. He thought the advantages attending the use of the injection more than offset the slight dangers. Formerly they employed three or four quarts. Now, at the Maternity Hospital, they injected only a quart in ordinary cases. As to the frequency of the accident, it was rare in the Maternity Hospital, but the young physicians there had been taking so much pains to guard against rupture that it had led, in his opinion, to an unusual number of stillbirths. The accident which they sought to prevent in retarding the birth of the head, was trifling compared with the death of the child. By two or three sutures the laceration could readily be repaired. He used wire, and had not found much pain from their being touched. The bichloride pad was considered sufficient without injections after the operation, and they almost invariably got union. In reply to a question whether in private practice he employed anæsthetics, he said he did not, or only as little as possible.

Dr. Clement Cleveland endorsed all that had been said with regard to the necessity for the immediate operation. He now used catgut suture. It would not dissolve before the ninth day. He used only hot water as a douche. He used the small darning-needle. The patient was placed on the left side, with the knees drawn up. Two sutures were inserted, if the rupture were not through the sphincter; one placed above would protect the others.

Dr. Goelet agreed as to the necessity for the immediate operation and thorough cleansing of the wound. But inasmuch as the vaginal tear and the perineal tear were not in the same line, the latter alone being median, he sewed up the vaginal line first, and the perineal line separately, using catgut in interrupted sutures.

Dr. Dudley endorsed Dr. Cleveland's method of operating with the patient on the side. The nurse lifted the buttock and exposed the whole line of laceration, when it was easily repaired. He used catgut directly out of the juniper. Dr. Goelet's remarks on the double tear were opportune. The pain attending the passage of the needle was trifling, but, if considered necessary, cocaine could be applied locally.

Dr. S. Baruch thought the tear was frequently due to the passage of the shoulders, and consequently the Goodell manœuvre in delivering the head should also be applied to the shoulders. He thought laceration of the perineum occurred in more than ten per cent. of primiparæ. He stated to the patient in advance that there would probably be a tear which would require a suture or two, so that after the birth of the child no objection would be made to the operation. The sutures should not be drawn so tight as in the secondary operation. He gave anæsthetics. The operation was one of the most successful in surgery.

Dr. Goffe had found the tear due not infrequently to the shoulders, or both the head and shoulders, and its taking place in different lines in the vaginal and perineal portions might be accounted for by the rotary motion in expulsion. He invariably gave chloroform, as the pain of the operation was great without it.

Dr. A. H. Buckmaster then read a paper,

A CASE OF EXTRA-UTERINE FŒTATION; DESTRUCTION OF THE FŒTUS BY THE GALVANIC CURRENT WITHOUT INTERRUPTIONS.

The patient had menstruated last in October, 1887. On December 26th she was seized with violent pain in the stomach, ringing in the ears, and faintness. Her physician supposed the internal hemorrhage which was evidently present had resulted from rupture of the fœtal sac in extra-uterine gestation. Similar attacks, but less violent, occurred subsequently. Dr. Buckmaster applied the electric current in February, when there was present an ill-defined mass, elastic to the touch, on the right side in the lower abdomen, the uterus being somewhat enlarged and crowded upward behind the pubes. A fluctuating elastic mass occupied Douglas's pouch, not unlike a small ovarian cyst, seemingly connected with the mass felt in the right iliac region. The uterus seemed to be free from it. Normal uterine pregnancy was readily excluded, and the diagnosis lay between an ovarian cyst fixed in the right side and extra-uterine pregnancy. The patient had increased in size considerably, lately. He applied one electrode covered with cotton against the floor of the tumor, and over the abdomen was placed a large mass of clay with sixty-four square inches contact for the other electrode; a Barrett battery of sixty chloride of silver cells was connected with the electrodes. The current was gradually increased and afterward decreased, the maximum being twenty milliampères, the duration being over twenty minutes. The patient was much relieved of pain. He saw her six days after the treatment, when there had been a decided change for the better; the appetite had returned, the circumference of the abdomen had decreased, the pain did not return for several weeks, the cyst had lost much of its watery contents. The second treatment was about six days later. The patient menstruated about

March 1st. The cyst could still be felt, and although much smaller, there was considerable tenderness.

The questions of interest in the case related to the diagnosis, whether the child was living at the time of the electric application, and whether the uninterrupted current was best for destroying the fœtus. He thought the child was living until the treatment was applied. There were three ways of using electricity for the destruction of the fœtus—the primary faradic current, the galvanic current with interruptions, and the galvanic current without interruptions, as it had been employed in this instance. The galvanic current with interruptions was considered liable to produce rupture of the sac. He preferred the uninterrupted current as used for fibroid tumors, and thought from twenty to one hundred milliampères, which could readily be employed, sufficiently strong to kill the fœtus. He thought it was best to apply the positive electrode within the vagina, and it should be brought in as close proximity with the fœtus as possible.

Dr. John S. Hawley then read a paper on

PRIMARY LAPAROTOMY FOR EXTRA-UTERINE FŒTATION,

in which he narrated a case and justified the operation in certain conditions. He had been able to find recorded but one other case in which laparotomy had been performed in the early weeks of extra-uterine gestation, before rupture of the sac, it being a recent one in the hands of Dr. Price, of Philadelphia. It was successful. The fœtus was of the seventh week.

His own case occurred in a woman who last menstruated in January, 1888, and who, as was altogether probable, aborted in March. Dr. Hawley did not see the patient again until April 27th, when he was informed that she had hemorrhage when on her feet, and that she had had an attack of pelvic pain a few days before. He was surprised to find a small, smooth, cystic, ovoid tumor, occupying the cul-de-sac to the left of the uterus. His diagnosis was immediately and positively made, based on the position and character of the enlargement, its recent development, and his knowledge of the former history of the patient. It was evidently a tubal pregnancy. The next day the tension of the tumor had perceptibly increased, and as rupture was threatened he thought it not advisable to trust to electricity, but that laparotomy should be done as soon as possible. April 29th, forty eight hours after the diagnosis, he removed the cyst intact by abdominal section. It occupied the left tube, and the floor of Douglas's pouch. The patient recovered without untoward symptoms. The fœtus was not more than of six weeks' growth.

The symptoms indicated impending rupture; the cyst was rapidly growing, having increased perceptibly in tension of its walls during a single day. Being thoroughly convinced that no time was to be lost, he advised the immediate operation. There were cases in which electricity was appropriate, but he thought its advocates made a mistake in condemning every other method and recommending this under all circumstances. The dangers of an operation after rupture had taken place were well known, but the risks incurred before rupture were not to be judged of by those known to exist after that accident.

Dr. Garrigues would repeat that in his opinion electricity was *the* remedy for extra-uterine pregnancy, especially during the first four months. He was surprised to hear from Dr. Hawley that there were only two cases on record in which the fœtus had been removed by laparotomy before rupture of the sac in the early period of extra-uterine pregnancy. He had inferred from the remarks of Dr. Martin, of Berlin, that it was not infrequently done in that city.

Electricity had been used in this country in between thirty and forty cases, without the loss of one, and with suppuration in but two, one of which should be excluded, as there was also puncture of the cyst, which under no circumstances should be made. Treatment by electricity was pre-eminently an American method. In the earlier case in Italy there was puncture by the electrode, an objectionable procedure.

As to the kind of current, he agreed with Dr. Buckmaster that the interrupted galvanic current was most objectionable, particularly as it might possibly cause rupture, but he preferred the faradic current to the galvanic without interruptions. There was not a single case on record in which faradization had caused any trouble. The strength of the current was increased very gradually.

Dr. Garrigues then recited a case very recently seen by him in consultation. The diagnosis of right tubal pregnancy between the third and fourth months was beyond a doubt. The woman was seized with severe pain in the abdomen ; the condition of the tumor was such as to make the case one in which Dr. Hawley had said no time should be lost in other treatment than by laparotomy. Yet the faradic current was employed, and the effect was immediate. The pain disappeared, and the next day, where there had been a tense globular tumor, he could feel a diminished hard mass, and ballottement had disappeared, as had also the peculiar areola around the nipples. He was fully convinced that the fœtus was killed at the first sitting, although the applications were repeated five days.

Further discussion was postponed until the fall meeting.

THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS.

Preliminary Meeting, held at Chicago, Ill., June 28, 1888.

Morning Session.

This Association held its preliminary meeting at the Palmer House, Chicago. Ill., June 28th, and was called to order by the Chairman of the Committee, Dr. C. W. Stemen, of Fort Wayne, Ind., at 9.30 a.m., who said the sole object of the meeting was to effect permanent organization, after which the surgeons of the different railroads would meet annually to develop this special and rapidly growing branch of surgery, to report cases, to exchange views, and to discuss the best means of treating railway injuries. The meeting was very largely attended, nearly all the distinguished railway surgeons of the country being present. Sixty-three railroads were represented. The Association starts out with a membership of six hundred, and promises to be one of the most active surgical associations in the United States, numbering as it does among its members some of the ablest and most eminent surgical lights of America.

Afternoon Session.

Dr. W. B. Outten, of St. Louis, made a few remarks on

POINTS IN RAILWAY SURGERY,

and said that out of one hundred and three railway injuries, caused by the passage of locomotives and cars over the parts, attended by him, involving the superior and inferior extremities, excluding injuries of hands or feet, more than one-third died from shock, and one-tenth died from shock without operative interference.

Dr. Outten then dwelt upon the subject of amputation, in which he leaned toward the secondary operation.

Dr. J. B. Murdock, of Pittsburg, in opening the discussion, said the main question was, whether we should adopt primary amputation, or, as a rule, resort to secondary amputation. If he correctly understood Dr. Outten, he advocated the secondary operation in crushing railway injuries. The time at which amputation should be performed was divided by some authors into the primary, intermediate, and secondary. Still further divisions were made by some. Dr. Hamilton makes what he calls the immediate operation, then the primary, intermediate, and secondary. The primary amputation is made within twenty-four hours of the accident ; the intermediate during the inflammatory period, and the secondary after suppuration sets in. Military surgeons contend that the mortality in primary amputation is much less than in the secondary. When a patient has sufficiently reacted from shock, Dr. Murdock performs amputation, and the sooner done the greater are the chances for recovery of the patient. We are more apt to have blood-poisoning by delaying the operation. As a rule, he would put himself on record as favoring the immediate operation.

Dr. W. P. King, of Sedalia, Mo., had been doing surgical work for railroads for twelve years; he had charge of a large railroad hospital, and had treated a great many men. It was an unfortunate circumstance for those who were injured on railroads to have to undergo amputation. While it was true of other accidents to which men are subjected, that limbs were saved when seriously injured, it was not so in cases where car-wheels had passed over an arm or leg; such members invariably had to come off. He had seen one case in which two car-wheels passed over the arm of a man, leaving their imprints behind. The limb was saved. The man carried a bundle of old clothes under his arm at the time, which Dr. King maintained saved the limb. He would not for a moment arrogate to himself that he saved the limb, nor, in fact, the limb of any man over which car-wheels had gone.

Dr. J. H. Bennett, of Wauseon, O., had practised his profession twenty-five years, during which time he had done considerable railroad surgery; and, since there had been so much said about antiseptic surgery, he would say he had never used carbolic acid or bichloride of mercury in the treatment of wounds—in short, he would go further, and assert that he had never used a drainage-tube. By using either of the antiseptic agents mentioned he held he would be adding to a wound a material or agent that would set up an inflammation.

Dr. C. B. Stemen, of Indiana, said the points set forth in Dr. Outten's paper showed that the author has had a large experience in railway surgery. He could not, however, let the remarks of Dr. Bennett pass without entering his protest against any man who opposed modern antiseptic surgery. Being in a position, as railway surgeon upon the Pennsylvania road, where accidents occurred now and then, and where sometimes little or no attention had been paid to antiseptics in the dressing of wounds and sending the patients on to him, he had experienced serious difficulty. With the rapid advances that have been, and are being, made in surgery, and from the testimony we have in this country and across the water, the day is passed when any man can consistently oppose antiseptic surgery. Sir Joseph Lister in his teachings had been the greatest benefactor of the present age in advocating it. Dr. Stemen could demonstrate to anyone the benefits resulting from an adherence to antiseptics in the practice of surgery. Although Lawson Tait, of Birmingham, Bantock, and others did not directly advocate it, yet all the necessary antiseptic precautions were carried out by them in their operating rooms.

Dr. J. H. Murphy, of St. Paul, said he had been a railway surgeon for twenty-five years, and the cases that most annoyed him were injuries of the spine. He had a case at present under his care of fracture of the spine, with paralysis of the lower limbs. Most patients with spinal trouble died. He would like to ask any member of the Association whether there was any manner or means by which spinal injuries could be relieved. He had resorted to every known form of treatment, but had failed. If anyone had met with success in the treatment of such cases he would like to know it—the methods they adopted, etc.

Dr. Outten closed the discussion by saying he did not wish Dr. Murdock to understand him as favoring secondary amputation. It depended upon the nature and extent of the injury. In some cases he would resort to primary amputation; in others he would not, but would endeavor to meet the indications at all times.

Dr. Murphy moved that when the Association reassembled it discuss injuries of the spine. It was in a large number of such cases that the railway surgeon was called upon to testify in court, and lawyers were better posted on this subject than anything else. *In short, they all read Erichsen.*

Adjourned till 8 P.M.

The Association reassembled at 8 P.M. First Vice-President, Dr. J. H. Murphy, in the Chair.

DISCUSSION ON SPINAL INJURIES.

Dr. Stemen, of Fort Wayne, opened the discussion by saying that, in 1874, a man working in a gravel pit in Illinois sustained a fracture of the eleventh dorsal vertebra with compression of the cord, and complete paralysis of the lower extremities. The patient was brought to his town in a pitiable condition. A short time after the injury he made the operation of trephining—cut down and removed an arch of the vertebra, with good results. Sensation was restored, and the bedsores healed kindly within two weeks after the operation. The man is alive to-day; but there is still slight paralysis of the lower extremities. He has since done the operation four times without benefit to patients. Notwithstanding what Ashhurst and others had said in regard to the unjustifiability of the operation, he would cut down and elevate the depressed bone, and if there was not serious injury of the cord he believed the operation would prove successful. He would advocate it.

Dr. David Prince, of Jacksonville, reported the case of a man who was thrown out of a wagon by a runaway team, so that the end of the wagon fell across his back, paralyzing the lower extremities and bladder. The tenth dorsal vertebra projected considerably beyond the eleventh. The patient never recovered the use of the lower extremities, and died about a year afterward. In view of what had been said by Dr. Stemen, he would not hesitate to cut down and remove an arch or two arches of bone to see what the results would be.

Dr. J. Harvey Reed, of Mansfield, O., said it seemed to him that we have to consider spinal injuries under two general heads: *First*, pseudo-spinal injuries; and, *second*, true spinal injuries. The worst class he had to treat, and which gave him the greatest amount of annoyance, was the pseudo class, which lawyers usually "trumped up." For instance, a fellow is hurt; he, perhaps, does not report to the surgeon at all, and in the course of six months sues the company; the surgeon is called upon to defend the company. The question the surgeon has to decide is whether that man really has spinal injury, or whether he has not. It is an important question—one that embraces finance and morality. The railway surgeon is morally bound to give that man the benefit of the injury he has sustained; at the same time, he is compelled to support the company if the patient plays the part of an impostor. He had found in his experience that this class of cases was the hardest for him to positively decide as to diagnosis, and to discharge what he considered his faithful, conscientious duty to the road to which he belonged.

As to true spinal injury, there was no question about the diagnosis.

He would agree with Dr. Stemen that, where there is fracture with compression of the cord, the proper thing to do is to cut down and relieve the pressure, just as we would relieve pressure upon the brain from a depressed fracture of the skull. These fractures may be slight; the pressure may be slight; yet grave results sometimes follow them, just as they do slight injuries of the brain which result fatally in six, seven, or ten years afterward. He was satisfied that surgeons had been too conservative in the matter of operating upon the spine. Dr. A. W. Ridenour, to his knowledge, had trephined the spine in a few cases with favorable results, and he could not see any tangible reason, nor, in fact, any more danger, attached to trephining the spine than the skull for lesions of the brain. If we can do it with immunity on the skull, why can we not do likewise on the spinal cord.

Dr. Reed then reported a case of fracture of the atlas. The man recovered. The accident occurred five or six years ago; the man came very near dying last week. The injury the fractured vertebra is producing on the spinal cord, in his judgment, would sooner or later terminate fatally.

Dr. Murdock, of Pittsburg, had only met with two cases of fracture of the spine which terminated fatally. He thought if any surgeon could instruct the Association how to treat fractures of the spine with a reasonable degree of success, he would confer a great benefit upon the members—whether by suspension, jury-mast, plaster-of-Paris, wiring, trephining, or what not.

He had recently read of a case of a new-born child in which the spinal cord was said to have protruded, or separation taken place, a few days before birth, in which the attending physician cut down, returned the cord, and wired all vertebræ separated together, and the child is still living.

What should be said of those cases in which we have supposed spinal injury without lesion? He would hold that there is no such thing as a serious injury of the spinal cord without a lesion. He did not believe there could be such a thing as a paralysis or any serious disturbance of the nervous system without some kind of change in the structure of the cord itself.

Dr. W. A. Ward, of Conneaut, O., fully agreed with Dr. Reed in regard to diagnosis. Although he had not had much experience with injuries of the spine, yet the remarks made vividly called to mind a circumstance in which he was placed. A lady in a wagon, attempting to cross a track, was struck by a gravel train that was backing up. She claimed to be seriously injured, and commenced suit for recovery of damages. The case ran along, and was finally set for trial. He had received a communication from the counsel of the railway, requesting him to examine the case and make a report of it. He examined the case carefully, and said that while he believed the woman may have been injured at the time, she was suffering from hysteria, and he would not be surprised to see her make a rapid recovery as soon as the case was settled and out of the way. The lady sued for $25,000, but the claim was adjusted for less than $2,000. A year or so afterward he inquired about the lady, and was informed of her death. He was unable to obtain any facts in the case, and while the question occurred to him whether he had erred in diagnosis, he was fully convinced that her death had no direct connection with the injury. Had the woman died before the case went to trial, he had no doubt the lawyers would have attempted to make the jury believe that death was directly attributable to the injury.

Dr. U. P. Gibney, of New York, being called upon to address the Association, said that while he was deeply interested in the subject of spinal concussion, or Erichsen's spine, his practice had been limited in that direction. He would like to have someone tell him how to differentiate between the pseudo and true cases of spinal trouble. This was not an easy matter to do. He thought that if we looked to neurology we would be able to discover, at all events, whether there be any lesion or not.

Dr. W. A. McCandles, of St. Louis, said that something over six months ago a brakeman was setting a brake, and the rod broke, throwing him back upon the car. He was brought to the hospital with lower extremities paralyzed. After being there some weeks, making no exhibition of feeling or sensibility in the lower extremities, he became suddenly blind in one eye, and described the sensation as if a sharp body had pierced his temple. About the same time he lost his voice, so that for months whispering conversations were held with him. He was very much interested in the case, because he thought the man was honest. Dr. McCandles consulted a neurologist, ophthalmologist, and laryngologist, which constituted a part of the consulting and examining board of the railroad to which he belonged. It was some time before a consultation was held with these specialists, however, as he believed the conditions were genuine. The man lay in bed five months without moving his limbs. First the laryngologist was called, who, after examining his throat, said there was no reason why the man could not speak and articulate distinctly, as the cords opposite came in contact with each other. Next, the ophthalmologist was called, who subjected the patient to the prism test, and said there was nothing to prevent him from seeing. Different tests were made to determine whether he could, by any possibility, be compelled to move his limbs. Pins and needles were thrust into him without avail. His legs were œdematous, cold, death-like. Shortly afterward, it is said, he met one of his comrades and joined him in a drink, and if the reports were authentic, the man proved to be a malingerer.

Dr. T. M. McIlvaine, of Peoria, Ill., said that some five years ago he was sent forty or fifty miles to see a woman who had, fourteen months previously, received a railway accident. She was thrown from her seat on to the floor, striking on her shoulders. She immediately got up; made no complaint. Her clothing was torn somewhat, for which she received $20 on account, and signed a release as part of the damages from the company. She went home, resumed her usual vocation, and for five months made no complaint whatever. Shortly after this she complained of a tender spot in the spine, which seemed to increase. Various reflex symptoms came on—vomiting, urinary troubles, etc.—until the woman was totally disabled. Suit was brought against the company for $5,000. Dr. McIlvaine was unable to find any lesion, and the surgeon who examined her at the time of the accident said there was no redness of the parts, and no pain. The case was traced; a detective put to watch the woman two or three months—she at the time was living forty miles from the railroad, in a small country-town. The case proceeded to trial; she won it. It was appealed, and she won it again. Dr. McIlvaine had kept track of the woman for four or five years, and he knew she was absolutely helpless. Whether there was a palpable lesion or not he was unable to say, but he thought there were a number of such cases that could not be controverted, and the railway surgeon may as well "face the music." The best way to do is to follow them up to find out whether they are malingerers or not.

The Association elected the following officers for 1889:

President—Dr. J. W. Jackson, Kansas City, Mo.

First Vice-President—Dr. J. H. Murphy, St. Paul, Minn.

Second Vice President—Dr. J. B. Murdock, Pittsburg, Pa.

Third Vice-President—Dr. A. W. Ridenour, Massillon, O.

Fourth Vice-President—Dr. B. L. Hovey, Rochester, N. Y.

Permanent Secretary—Dr. C. B. Stemen, Fort Wayne, Ind.

Assistant Secretary—Dr. J. H. Tressel, Alliance, O.

Corresponding Secretary—Dr. E. R. Lewis, Kansas City, Mo.

Treasurer—Dr. Harvey J. Reed, Mansfield, O.

Next place of meeting, St. Louis, Mo.

Lactic Acid as a Caustic has been greatly praised by Mosetig, Moorhof, and others, but Spitzer and Hermann from their experience conclude that: (1) The pain produced by the cauterization with lactic acid is at least as great as that caused by any other caustic. (2) The patients prefer invariably any caustic to lactic acid. (3) The action of lactic acid resembles that of other caustics, but is less energetic. (4) Healthy tissues are not spared by this any more than by any other caustic. (5) Lactic acid has to be employed for a much longer time than chloride of zinc and other energetic caustics.—*Boston Medical and Surgical Journal.*

Correspondence.

OUR PARIS LETTER.

(From our Special Correspondent.)

A TOUR THROUGH THE RIVIERA.

Paris, May 23, 1888.

Sir: I have lately returned from a hasty tour along the Riviera, where I spent the whole month of March. I commenced my journey in the North of Italy, visiting Turin, Milan, Genoa, etc. These places are certainly well enough known and require no further description from me. I wish, however, to say a few words about the new Cemetery of Milan, which lies to the northwest of the city. It has a magnificent façade, is enclosed by colonnades, and is said to be one of the finest Campi Santi in Italy. A section of the cemetery, which covers an area of five hundred acres, is appropriated to the "Tempio Crematorio" for the burning of dead bodies, which was presented to the town in 1876 by a Mr. Keller, of Zurich. On visiting the Crematoria, the guardian of the place showed me some calcinated substance, which he said weighed two kilogrammes, and which was the remnants of the body of a man who had died in a hospital ten years ago, and who weighed at the time of his death one hundred kilogrammes. This, he said, was the first experiment tried in Milan in the way of cremation. The body was burnt by wood fire. Specimens of cremated bones of Romans were also shown me, and were supposed to date from before the Christian era. Bodies are now burnt by gas instead of wood, as being more expeditious, for by this mode it takes from fifty minutes to one hour to incinerate the body of an adult, whereas by wood it takes two hours. The gas is produced by the burning of wood in preference to coal, as the latter procedure blackens the bones. On questioning some of the inhabitants as to what they thought would be the future of cremation in their country, they replied that it was not likely to take, as most people, whether from deep-rooted superstitious prejudice or religious motives, appear to have a decided objection to it, as they have yet to learn the advantage it has over inhumation. In any case, cremation seems to be making very slow progress in Milan, as I was informed that scarcely a hundred bodies per year are submitted to the process. The structure of the Crematoria is of marble, and the architecture is a modification of a Greek temple. There are two ovens in the building, so that two bodies can be cremated at the same time. The ashes are preserved in urns, some of which are arranged in niches of the building, while others are placed in detached monuments erected for the purpose.

Genoa is singularly constructed around a small bay, on shelving ground, rising rapidly from the water's edge to the height of from five hundred to six hundred feet. The old part of the town is a labyrinth of crooked and narrow streets, and frequently so steep that steps have to be cut in them, the general aspect of which is that of an Oriental city. Besides the old palaces and churches, there is nothing of much interest in the place. The new hospital, however, deserves a passing notice. The existence of this hospital is due to the ducal house of Galliera, whose philanthropy is well known. It is called the Saint-André Hospital. It was begun about two years ago, and opened on March 14th last. It is situated on Mount Carignano, and built on a magnificent scale, on the pavilion system, two stories high, and capable of containing four hundred beds, sixty of which are for paying patients. Two-thirds of the hospital are intended for the natives, and the other third for foreigners. The wards are lofty and well ventilated, and are not to contain more than twenty beds each. The furniture and bedding are comfortable, and the general appliances of the rooms are composed principally of iron and glass. Such a hospital is certainly a great boon, and the foundress of the same deserves the gratitude of the inhabitants. The municipality of Genoa, in recognition of the Duchess of Galliera's munificence, have presented her with a beautiful commemorative medal, coined at the Roman mint, bearing her portrait with a suitable inscription in honor of the event.

At Genoa we enter the Western Riviera, which extends along the coast of the Mediterranean and ends at Hyères, being two hundred and three miles long. The climate along this strip of land is about the same throughout, and if there be any difference it may be said to be imperceptible. Yet each station has some peculiarity which suits some people better than others, this peculiarity being more frequently accidental and social, such as the general surroundings of the place, and many other little things which exercise a powerful influence upon the health and well-being of the mind and body, even more than the mere fractional difference of temperature. None of the protecting mountains of any of the stations are sufficiently high, precipitous, and united to ward off the cold winds when the higher mountains behind are covered with snow. All the ridges have deep indentations through which the cold air, as well as the streams, descend to the plains. Hence no station is, properly speaking, exempt from cold winds, and all delicate persons must ever be on their guard against them. All the stations suffer more or less from the famous mistral, a northwest wind. The mean winter temperature of the Riviera is 47.4° F. for Hyères, which is at the western extremity, and 48.89° F. for San Remo, at the eastern. But of all the stations, none can be compared to Monte Carlo or Monaco, whether as a resort for health or only for pleasure. The towns of Monaco and Monte Carlo are most picturesquely situated on high promontories which bound a bay on either side, having as a connecting link the Condamine, which is considerably lower, and forming with Monaco and Monte Carlo the background of an amphitheatre. The position of Monaco certainly justifies the title of the "beauty spot of the Riviera," given to it by Dr. T. H. Pickering in a work published by him about six years ago. The houses are situated from about two hundred to three hundred feet above the sea, amid the beautifully olive-clad hills which are blended with the mountains at the back, rising several thousand feet high, and forming a barrier which completely shelters it from the north winds. Dr. Pickering observes that, as there is neither break nor gap in this mountain-screen, the dreaded mistral or northwest wind is never felt, while the northeast and northerly winds pass over the mountains and the town into the sea. The air, according to this author, who has been in practice at Monte Carlo for several years, is drier, more fresh and exhilarating than at any health-resort on the Riviera. Almost all chronic affections, including scrofula and consumption in its earlier stages, may be advantageously treated in the Principality, and even in summer the place need not be deserted, as, judging from the meteorological observations published, the climate is equable and dry; but even when hot it is tempered by cool sea-breezes. To my mind it is also well suited for a sea-bathing station, and would be a desirable resort for debilitated constitutions from whatever cause, for the old as well as for the young, for those who have resided many years in tropical countries—in short, for anyone requiring absolute rest, change of scenery, and change of climate. Its proximity to the other stations on the Riviera, whether on the French or Italian side, renders it convenient for excursions to those places in winter or summer, and those wishing to lead a quiet and retired life would find ample accommodation at the Condamine or in the town of Monaco. I was much struck with the luxuriant vegetation at Monaco, particularly the semi-tropical plants and trees, such as the lemon, orange, eucalyptus, and aloes, the latter growing to a height not known out of the tropics.

Mentone is charmingly situated round a large bay, called the Bay of Mentone, which is divided into two smaller bays, viz., the eastern and western, by a rocky promontory one hundred and thirty feet high, on which the old town is built. Mentone is protected on the north by a girdle of rocky mountains, and is considered one of the most favorable spots on the Riviera for a winter residence. The eastern bay in particular is thoroughly sheltered, and has a mean temperature in winter of 50° F. The streets are narrow, dirty, and even slippery, and most of the roads are badly paved. The new town, however, which stretches out a great way along the beach, is in better condition. Several small brooks empty themselves into the western bay. The vegetation is luxuriant, consisting chiefly of orange and lemon groves interspersed with gnarled carob-trees (Ceratoria siliqua), figs, olives, etc.

Nice, which is 9½ miles west from Monaco, has all the advantages and drawbacks of a large town. In winter it is the rendezvous of invalids, as well as of persons in robust health, from all parts of Europe, especially from England, Russia, and Germany, and even from America, who assemble here to escape from the rigors of a northern winter. In summer the town, like all the others on the Riviera, is deserted. It is most beautifully situated, facing the south and looking on to the Mediterranean; it occupies a plain bounded by the limestone summits of the Maritime Alps, whence descend fertile wooded ridges composed of a reddish conglomerate and a gray-blue clay of the Pleiocene period. The climate is rather colder in winter than that of the neighboring stations, especially if the mountains are much covered with snow. The want of altitude of the nearest mountains, their great distance, and the wide gaps between them, render Nice the most exposed of all the Riviera stations. The mistral is here well known, and to this must be added the northeast wind, which is colder here than elsewhere, as it reaches the town immediately after passing over the snow-clad Alps, and this renders it unsuited as a safe winter resort for consumptive patients.

Cannes is picturesquely situated on the Gulf of Napoule, and is 19¼ miles from Nice. It consists chiefly of a main street, parallel with which along the coast runs the Boulevard. The remainder of the town is composed of hotels and villas, which are situated on the hills and are principally occupied by English families. Some of the best French society is also well represented here. The climate, though dry and sunny, is said to be at times treacherous, and Dr. Hassall writes that, while Cannes possesses a winter climate well suited for children, elderly people, and many classes of invalids, especially those who require a stimulating atmosphere, it is not so well adapted for the majority of those suffering from affections of the respiratory organs. On the other hand, we find in Madden's "Resorts" that the electrical condition of the climate of Cannes, as well as its equable warmth and dryness, together with the stimulating properties of the atmosphere, indicate its fitness for scrofulous and lymphatic temperaments.

Hyères is rather off the line and is about three miles inland. It has long been frequented as a winter residence by persons suffering from pulmonary complaints. It is situated on the southern slope of a spur of lofty mountains, and, being at some distance from the sea, it has the advantage over the other stations of the Riviera in that from this circumstance it is more favorable for cases of consumption and other diseases than the stations in the immediate proximity of the sea. It is, however, not sufficiently protected from the mistral, which in fact is more or less the bane of the Riviera. It contains beautiful gardens and a fine avenue of palm-trees, which here flourish most luxuriantly. The climate of Hyeres is said to be less stimulating and exciting than at Cannes and Nice, and although it is not so gay as the other stations of the Riviera, it is well suited as a winter residence, and generally it is said to be fitted for old people and for children, or young persons of lymphatic temperament or of a scrofulous diathesis. Even persons in health would find enjoyment in the place, as the beauty of its environs and its rural character render it a most agreeable place of winter abode. Hyères is the first station of the Riviera in passing from Marseilles and Toulon. It is the nearest to England, and only 18¼ hours from Paris. Marseilles and Toulon maintain their reputation as being the filthiest towns in the South of France. The old port of Marseilles is simply a cesspool, and the new one is nothing better, but the environs of both these towns are all that can be desired.

FLORIDA AS A RESORT FOR CONSUMPTIVES.

To the Editor of The Medical Record.

Sir: In the issue of The Medical Record dated June 16th, in your editorial on "The Selection of Climate for Cases of Pulmonary Phthisis," is an excerpt from the article by Dr. Frederick I. Knight, giving certain conclusions with regard to the selection of climate for cases of phthisis. Among the conclusions I notice the 4th: "Cases of advanced disease with cavities or severe hectic symptoms. These should remain at home. But sometimes the moist, warm climate of Florida is beneficial." I scarcely feel that I am prepared to enter fully into this subject just now with statistics or meteorologcial data, but feel that, for suffering humanity, it is proper that those of us who have had practical experience in this matter should not hesitate to relate it. Every thinking man must know how very unsettled is the question as to what climate will be best for his consumptive patient, and we can scarcely doubt that a climate which will benefit a given case of catarrhal phthisis will injure another, or at least will not benefit it. I do not feel that I would do wrong were I to enter an absolute protest as to the doctor's fourth conclusion, as I have seen many such cases come to Florida—I mean advanced cases of phthisis with cavities and severe hectic symptoms, and do not believe that they are benefited by the climate. I have had occasion often to regret that such cases had not remained to enjoy the kindness and comfort of home, and I believe the experience of other physicians tends to the same conclusions. I have felt conscientiously obliged at times to advise the return home of such cases. As to what cases it is best to send to Florida, is a discussion into which, as I have said before, I feel scarcely prepared just now to enter. This may be said, however, that the business population of Jacksonville contains a considerable percentage of intelligent active gentlemen who have moved into the State from North and West on account of catarrhal affections of some portion of the respiratory tract; many of them are in good health here, and can live nowhere else; some of them positively assert that they have recovered from phthisis since coming to Florida. I believe the most reasonable conclusion to be reached is, that in the severe climates of the North and West there are many who by inheritance or exposure develop bronchial catarrh or incipient pulmonary phthisis, and who, were they to remain in the same climate, would die of that disease, but who, upon removal to a warmer climate, recover, or their disease remains dormant. It is probably this class of cases that are benefited by coming to Florida.

Respectfully,

C. Drew, M.D.

Jacksonville, Fla., June 21, 1888.

THE MEDICAL SERVICE ON THE DUTCH STEAMSHIP LINE (ROYAL MAIL TO THE NETHERLANDS.)

To the Editor of The Medical Record.

Sir: Wherein lies the attraction of the seafaring life may be difficult to explain. Certain it is that at some period of his life almost every young man has a desire to be a sailor; with some it is the love of adventure, with others it is the desire to see new sights in strange lands, but there are charms apart from these. The ever-changing sea in its restless activity is a never-ending source of enjoyment. To-day calm, to-night ruffled, to-morrow raging with the storm. One never wearies watching the infinity of variety of the waves, from the long "ground-swell" to the short, "choppy" sea.

Barring seasickness, an ocean voyage is a very enjoyable affair.

The vessels of the Netherlands American Steamship Company ply between Holland (Amsterdam and Rotterdam) and New York. The fleet consists of seven steamers, built with a view to safety and carrying capacity rather than speed, although some of the ships are quite fast. They are first-class iron or steel, varying in length from two hundred and fifty to three hundred feet. They are controlled by a Dutch stock company and sail under the flag of Holland.

Ship surgeons are appointed by the agent in New York, subject to the approval of the Board of Directors in Holland.

Applications are filed in the order in which they are received, but appointments are made in the order that suits the agent. No examination is required, but applicants are required to show their diplomas. References are always necessary.

The number of applications for these positions is indicative of the overcrowded condition of the profession, there being fifty or seventy-five sometimes on file. The doctors, as a rule, are young men just out of college or having filled hospital appointments, preference being given to the latter class in making appointments. The ships are now carrying American surgeons; why, is not apparent, as no true Hollander would acknowledge that anything produced out of his country was as good as the home products.

There is a general idea that ship surgeons, as a rule, are incompetent, and there is reason for this. In England and some other countries men are allowed to ship who could not legally practise on land. It is a lazy life. There is little incentive to study, so that the tendency to get into a rut is greater than on land. At present the *personnel* of the service is excellent, most of the surgeons having held hospital appointments.

In rank the doctor is next the captain, being on an equality with the first officer and chief engineer. These are the only officers who eat in the first cabin, the captain sitting at the head of the first table and the doctor generally at the head of the second.

The surgeon's quarters are above deck on most of the ships, although sometimes below, perhaps about eight by ten feet, with the door on the inside and a port-hole a foot in diameter toward the sea. The bed consists of a bunk three feet wide, which is wide enough when the ship is rolling. There is a bench on one end, with drawers and closet on the other. The furniture consists of one camp-stool. Some of the rooms are carpeted. The doctor's room serves as a pharmacy, and contains all of his supplies, for he must put up his own medicines. A reasonable supply of medicines is allowed on his requisition. All medicines are bought in Holland. The preparations are rather crude, the Dutch being strangers to the elegance in pharmaceutics to which the Americans are accustomed. Scales and all necessary appliances are supplied. Each ship has an amputating case, also a pocket case, obstetrical forceps, etc. In addition to medicines special diet may be ordered for steerage passengers or any member of the crew, and this is often done—beef-tea, eggs, soups, etc., being supplied in cases of real sickness.

There are two hospitals in connection with the steerage on each ship, one for men and one for women; but, as a rule, one of these is used for other purposes, and sometimes, if the ship is crowded, passengers are put in the other. Medicines are furnished by the company free to all passengers and crew.

The wages are eighty guldens ($32) per month, and twenty-five cents per head for each passenger carried—the salary and head-money averaging perhaps $40 a month. Fees are not allowed, even in venereal cases. While in Holland he must pay for his meals. Occasionally a grateful patient will favor him with an honorarium; but this source of profit, which is considerable in some transatlantic lines, amounts to very little here.

When on duty, and especially going out and coming into port, the doctor, in common with the other officers, is required to wear a uniform consisting of a suit of blue and a cap. The latter has a blue velvet band, with the company's flag in front, surrounded by a gold wreath. There is also a sack-coat, with the word "Doctor," in gold script letters, on each lapel. The company's buttons, in brass or gold, are used on the coat and vest.

Voyages are from Holland and return. Two or three days before sailing, articles are signed that are binding for the round voyage to New York and return. The surgeon ships as "scribe," to evade some law of Holland. He cannot leave in New York without deserting, nor can he be discharged here except by special agreement.

On the day of sailing the doctor must inspect the steerage passengers. He is held responsible for admitting any affected with contagious diseases, or any that, by reason of sickness, age, or imbecility, are incapable of earning a living in this country, as all such would be returned at the expense of the ship. This inspection is rather hurried. The passengers simply pass in review before the doctor, who stands at the end of the gang-plank as they go aboard.

All over sixty years of age, all sick or debilitated, must be reported to the captain, or to the agent of the company. Inspection over, the doctor's duties are done, so far as embarkation is concerned.

The ship leaves port on Saturday. About three days later steerage passengers are again inspected at the time the tickets are taken up. All who do not show a scar are vaccinated. As a matter of fact, from ninety to ninety-five per cent. show evidence of previous vaccination. Further, it is very rare for the vaccinations to take. All steerage passengers are furnished a card bearing the legend "protected," with the name of the ship and signed by the surgeon on one side, while the reverse bears the inscription: "Keep this until you reach your destination," in English, Dutch, German, and French.

The daily routine is as follows: Breakfast, 7 to 8 A.M.; visit to steerage, 9 A.M.; daily report to captain; lunch, 11 A.M.; coffee, 1 P.M.; visit to steerage, 4 P.M.; dinner, 5 P.M.; supper, 9 P.M.

All sickness is to be reported to the captain, whether among passengers or crew. It remains with the doctor to relieve any of the crew from duty; but there is not much red tape about the matter. He generally informs the head of the department if any of his men are unable to attend to regular duty.

Sunday is much as any other day. No religious services are held, and, were it not that some of the passengers put an extra touch to their toilets, one would scarcely know the day from the rest, save that the dinner is perhaps a trifle better than on other days.

It is regarded as part of the doctor's duty to entertain the passengers, especially the lady passengers. Having more leisure than any of the rest of the officers this duty naturally devolves on him, so that he gets the reputation of being a ladies' man.

This routine is unbroken until the arrival at quarantine. The doctor must always be ready to see anyone on board the ship who may wish to consult him.

The practice is not extensive, consisting mainly of minor ailments, with some venereal cases, and an occasional fracture or obstetrical case. It is said that steerage passengers will time their voyage so as to be confined on board, thus saving an obstetrical fee. The forced relation to patients is sometimes unpleasant; many annoy the surgeon by coming in season and out of season with every little ache.

The doctor is not busy, as the vessels of this line do not carry the large number of passengers some other lines do. Generally there are from one hundred to three hundred in the steerage westward, and perhaps one-third as many going back. In the season the cabin is crowded from New York to Holland in the spring, and the other way in the fall. The capacity of the ships averages about fifty first and second class, and five hundred to one thousand steerage. The number of passengers varies from fifty to five hundred, counting all classes. The number of the crew is from fifty to sixty.

The passage westward from Amsterdam or Rotterdam takes from twelve to fifteen days, according to wind and weather. The course lies directly across the North Sea, then skirting the southern coast of England, passing in sight of Dover, Dungeness, Isle of Wight, Eddystone Lighthouse, and finally Lizard Head and the Scilly Islands. From the Lizard passing steamers signal their name and destination, and are reported by telegraph. After passing these places the ship is out of sight of land. Vessels become scarce. A week may pass with nothing in sight but sea and sky. On some voyages a number of vessels may be sighted, often so far away that they cannot be recognized. In the spring the monotony may be broken by the sight of an iceberg. Occasionally a whale will be seen, sometimes schools of other fish. The gambols of porpoises around the ship always afford passengers much amusement. At night the phosphorescence produced in the wake of these fish is really beautiful.

On board, passengers begin to appear one by one as they recover from the *mal de mer*. Time is variously spent; some read, some play; all sleep, all eat—some more, some less, according to inclination. The course of the vessel takes her within a hundred miles of Newfoundland. During certain seasons of the year hundreds of fishing vessels are sighted. A little later a pilot is taken on board, often two or three days before arriving at port.

Finally the shores of Long Island are sighted, and everyone is on the lookout for the lighthouse on Fire Island; passing this, Sandy Hook is soon reached. From this point the arrival of the ship is telegraphed to New York. This is sixteen miles from the city, but it takes at least two hours to travel that distance, with the inspection at quarantine by the port doctor, and after this the Custom-House officials. No one is allowed to leave or board the ship until after the doctor's inspection.

Arriving at quarantine, the health officer inspects all the steerage passengers, requiring them to show their vaccination cards. The inspection is conducted on deck, each passenger passing in review before the health officer. If any are sick, they are visited in the hospital. Cases that have refused vaccination are not detained unless suspicious. Under certain circumstances the cabin passengers may be inspected, but this is rare. The ship surgeon is required to report all sickness, deaths, and births occurring during the voyage to the health officer. The doctor has nothing further to do with the ship's papers, the bills of health being attended to by the captain or purser.

The ship is required to have a bill of health from the United States Consul at the port from which she sailed, said bill must state the number of deaths from contagious diseases in the last weekly report previous to the date of sailing. Among the clearance papers from the Custom-House is another bill of health. These are both inspected by the health officer. If the bills are "clean," and there is no contagious sickness on board, a written permit is given to land; if the bills are "foul," the vessel may be detained at quarantine.

Proceeding up the lower bay, the United States Custom-House officers next board the ship. Receiving copies of passenger, baggage, and freight lists, and other papers, they allow the vessel to proceed to the dock. Arriving there, the doctor is not permitted to leave the ship until all the passengers are landed.

The ship remains nearly a week in New York. The surgeon is required to be on board an hour every morning and an hour in the afternoon. He must report to the officer in charge on leaving and coming on board. On the return voyage his duties are not so arduous. There is no vaccinating, no inspecting, no health officer. The espionage over immigration is more strict here than in Holland.

The route on the return voyage is more to the south, and the distance somewhat greater than on the outward voyage. The Gulf Stream flowing eastward produces a stronger current than in the higher latitude. The return trip is made in eleven to thirteen days. Arriving in Holland the vessels to Rotterdam sail up the river Maas fourteen miles before reaching their destination; vessels for Amsterdam go through the North Sea Canal, fifteen miles long, the waters of which are in some places as high as the second story of the houses inside the dykes.

The requisition for medicines should be given to the captain before landing. It must have his approval. Arriving in port the crew is paid off. Cooking on the ship is stopped. The officers and most of the crew are kept under wages, getting their meals on shore. It is customary for ships to allow shore money for this purpose, but here an exception is made in the case of the doctor. Other officers are allowed a dollar a day, the crew fifty cents.

The surgeon has this time much to himself. When in the city he is required to report once a day. Often he can get away for a week or ten days. This gives an opportunity to visit England and the Continent. In about two weeks the ship is ready for another voyage. The surgeon is required to be on hand a few days before sailing, to sign articles, attend to medicines, vaccination points, etc.

The life has its peculiar charms. The ever-changing scenes, the turmoil at embarkation and debarkation, the change of faces and scenery every few weeks, all tend to make one contented and happy, but it is a lazy life. Reading and study are almost out of the question. It is said that the sea will spoil any doctor in three years.

Army and Navy News.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from July 1 to July 7, 1888.

BAXTER, J. H., Colonel and Chief Medical Purveyor. Will proceed to New York City on public business connected with the Medical Department, and on completion thereof will return to his station in Washington City. S. O. 150, A. G. O., June 29, 1888.

BENTLEY, EDWIN, Major and Surgeon. Retired from active service, July 3, 1888, by operation of law. S. O. 153, A. G. O., July 3, 1888.

JOHNSON, RICHARD W., Captain and Assistant Surgeon. Designated as medical officer for a camp of instruction in rifle practice to be established at Fisher's Island, N. Y. (near New London, Conn.), on July 2, 1888, and to continue during the months of July, August, and September; and ordered to proceed to Fisher's Island in proper season and report to the commanding officer for duty. S. O. 131, Division of the Atlantic, June 28, 1888.

CROSBY, WILLIAM D., First Lieutenant and Assistant Surgeon. Leave of absence extended one month. Par. 8, S. O. 151, A. G. O., June 30, 1888.

CLENDENIN, PAUL, First Lieutenant and Assistant Surgeon. Leave of absence granted in S. O. 59, Department of Texas, June 4, 1888, extended one month. S. O. 149, A. G. O., June 28, 1888.

Official List of Changes in the Medical Corps of the United States Navy for the week ending July 7, 1888.

MOORE, A. M., Surgeon. Ordered to Naval Station, New London.

AUSTIN, A. A., Passed Assistant Surgeon. Detached from Gedney, and wait orders.

PECK, GEORGE, Medical Director. Placed on retired list, 7th instant.

TWO DEATHS FROM POISONING BY CHLORATE OF POTASH, WITH AUTOPSIES.[1]

By GEORGE L. PEABODY, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK CITY; ATTENDING PHYSICIAN, NEW YORK AND BELLEVUE HOSPITALS.

I DO not present these cases as embodying anything new in their symptoms or lesions, or in the conclusions to which a consideration of them will lead; but only because it seems to me that it might interest the Society to see the lesions which this poison produces, and because it seems right to add my warning to those of others that have preceded me. Of all the evidence which has been adduced touching the dangers attending the use of this drug in large doses, none has been more emphatic than that of Jacobi[2]; and to one familiar with his writings, it would seem superfluous for others to echo his warning cry. Yet before Jacobi's classic work, the literature of this subject was by no means scanty. Marchand[3] had given an accurate and systematic account of the lesions produced by chlorates of potassium and sodium, as shown by clinical and experimental studies. Fountain,[4] of Iowa, had written his panegyric on the potassium salt, and in his endeavors to prove its harmlessness had killed himself by taking an ounce, after repeatedly having taken doses of half of that amount. For periods of six consecutive weeks he had given it in daily amounts of half an ounce to several patients, and thought that he had thus cured their pulmonary troubles. Tacke had shown its poisonous effects in 1878, and others, as shown by Jacobi, had published isolated cases of death brought about in this way.

Notwithstanding all these witnesses to the serious dangers attending the use of this drug, it is still freely sold in the shops, and freely used by the people in large quantities, and considered by the laity and by many doctors as belonging among the harmless or indifferent drugs. It is still looked upon as an agent that in a given case *may* do good, and *certainly will not do harm.*

It is somehat remarkable that in the recent text-books on materia medica and therapeutics but little reference is made to the dangers attending its habitual use. Binz[5] gives in full an account of these dangers, and Nothnagel[6] and Rossbach do also; but most of the books generally accessible in this country make only passing allusion to them.

I have brought here this evening for demonstration to the Society pieces of liver, kidney, and spleen which still show the peculiar chocolate color well, and I have placed under these microscopes sections which show admirably the kidney lesions, to which I shall make specific reference in a few minutes.

In my cases death seemed to be the result of the effects of several conjoined lesions. The potassium element in the compound seemed to produce the usual heart-depressing effect of the potassium salts, and very great feebleness and frequency of the pulse resulted. The specific effect upon the hæmoglobin, in consequence of which it was largely changed to methæmoglobin, was very distinctly manifested in the dyspnœa and the altered color of the victims. Methæmoglobin is incapable of assimilating and transmitting oxygen, and hence, though respirations be full and frequent, the evidences of defective oxidation become manifest. One of these, in my cases, was fatty degeneration of the heart-muscle; another, cyanosis. Another, and a very prominent lesion, consists in the more or less complete blocking up of the renal tubules with masses of disorganized blood-cells and methæmoglobin, in consequence of which complete suppression of urine results, with the usual clinical picture of uræmia. This latter is commonly, but incorrectly, regarded as the result of an acute nephritis. There is no nephritis produced by this poison; but suppression, which is often complete, is brought about by the mechanical obstacle to the egress of urine rather than by a structural lesion of the kidney.

Death seems to result, then, from these combined causes; namely, feebleness of the heart, dyspnœa, and suppression of urine.

If I should be called upon to treat a bad case of poisoning by this agent early enough to warrant it, I think I should proceed as in a bad case of poisoning by coal gas, *i.e.*, I should free the blood of as much of its offending contents as possible by copious venesection, and immediately replace the damaged blood by healthy human blood. It is plain that infusion of salt solution, under such circumstances, would be useless.

I will not detain the Society further, but will proceed with my cases and the demonstration of the lesions which are to be seen in their organs.

CASE I.—Catharine M——, aged twenty, Ireland, single, servant, was admitted to the New York Hospital, service of Dr. E. L. Partridge, on April 10, 1888, at 4 P.M. She had taken on the previous evening two tablespoonfuls of chlorate of potash by mistake, having intended to take a dose of Rochelle salts. She was in a condition of such very profound prostration on her admission that it was not deemed advisable to subject her to any questioning as to her previous history or her family history. Her temperature at the time of her admission was 99° F., her pulse was 136, and her respiration was 32. Her surface was very cyanotic, her face being nearly purple in hue. No attempt was made to wash out the stomach, inasmuch as fourteen hours had elapsed since she had taken the poison, and she had vomited freely. Her breathing, though rapid, was not labored, and there was apparently no subjective dyspnœa. After she had been put to bed she lay usually quiet, but at times she would become quite restless, tossing about in the bed and rolling from side to side. After a short period of restlessness she would again subside into a quiescent condition. Her pulse, though not very rapid, was very feeble, and it was thought necessary to resort to pretty active stimulation.

She was given whiskey, fluid extract of digitalis, and tincture of strophanthus, by the stomach; and, later, the two former were given subcutaneously. She had vomited much prior to her admission to the hospital and was nauseated when she was brought there, and vomited abundantly a bile-stained fluid after her arrival. As anti emetics there were given ammonia, with cracked ice, sodium bicarbonate, and cerium oxalate. Mustard-paste was applied to the epigastrium, and her feet were soaked in hot mustard-water. The success attending these procedures was not very great.

[6] Arzneimittellehre, Berlin, 1887.

At 6 P.M. her temperature had risen to 104°; her pulse and respirations were not materially changed. During the night, attempt was systematically made to stimulate her heart with whiskey and digitalis, both internally and subcutaneously, and, as her extremities became cold, hot bottles were applied to her feet. During the night her bowels moved three times, the fæces being always of a dark-brown color and of semi-solid consistency. Urine was passed involuntarily; this also had a very dark chocolate color. A few ounces of urine were obtained by catheter. It presented a similar appearance. It was found to contain many blood-cells and large masses of altered hæmoglobin, and much albumen.

The next morning her temperature had fallen to 99.4°; her respiration and pulse had diminished in frequency and improved somewhat in character. By noon, however, this apparent improvement in pulse had disappeared and the heart was again profoundly weak. In the afternoon her temperature again rose, and reached 101.2° at three o'clock. At this time oxygen gas was given freely, without any improvement resulting either in her color, pulse, or general condition.

I saw her at this time, and was impressed by the very extraordinary color of her skin and conjunctivæ and lips, as well as by the very great restlessness which she manifested. The combined effects of intense anæmia with a cyanotic hue apparently beneath the surface, together with a very distinct sepia-brown or chocolate tint where the epidermis was thin, produced a most remarkable and unusual effect. She was at this time very restless, and constantly tossing about the bed. Her pulse was perceptible at the wrist, but was so feeble that it could with difficulty be counted.

She grew rapidly weaker, her respirations increased in frequency, and, though they were deep and full, and though she was allowed to inhale pure oxygen, as might be expected from the physiological action of this poison there was no relief of the dyspnœa and no improvement in the patient's color. She slept steadily after this time, and died quietly at 3.35 P.M., thirty-seven and a half hours after she had taken the poisonous dose.

I made the autopsy twenty-five minutes after death. Her body presented the appearance of a well-nourished young woman. Rigor mortis was absent. There was some œdema of the legs. The color of the body was not materially changed by death, except that the cyanosis of the surface was less marked, and with the subsidence of the blood from the surface there appeared a slight hue of jaundice added to the anæmia and chocolate-color.

The site of the application of the mustard-paste, the epigastrium, was exactly marked out by subcutaneous hemorrhage. Instead of being merely bluish, it was of bluish-brown color.

The abdominal and thoracic muscles were of very dark-red color. The blood in the vessels of the neck and in the great vessels was all liquid, and of a very dark chocolate color. The clots in the heart were very soft and friable and of the same color as the blood in the vessels. The heart was soft and flabby. There was slight dilatation of the left ventricle, and fat was to be seen in the papillary muscles which control the mitral valve. The valves were competent, and the size of the heart was normal. The lungs were structurally normal, but their cut surfaces were very brown in color. The spleen was large, firm in consistency, and of a very distinct chocolate color. Exposure to atmospheric air caused no change in the color of the cut surface of this or any other of the organs. The kidneys were large, their capsules not adherent, their surfaces smooth, and of chocolate color. Both kidneys were found to be diffusely stained with the same chocolate-colored blood, and consequently the markings, on cutting them open, were not found to be distinct. The blood in the brain was found to present the same peculiar discoloration as the blood elswhere; but the brain and membranes were structurally normal. The stomach contained a pint and a half of a thick, dark-colored fluid, with a distinct admixture of bile; but in structure this viscus was normal. The solitary follicles were large, and Peyer's patches were pigmented; but otherwise the intestines were normal. The liver was normal in size; it was chocolate-colored, but not quite so dark-colored as some of the other organs. The bladder contained three ounces of urine, which was of a dark, brownish-black color, and very untranslucent.

There was a recent corpus luteum in the left ovary. Both ovaries were somewhat large. The uterus was normal; its mucous membrane was thick, soft, and velvety in appearance.

By microscopic examination the chief lesions of importance were found in the heart and kidneys. Very extensive fatty degeneration was evident in the heart, especially in the papillary muscles of the left ventricle. Many of the straight tubes in the pyramids of the kidneys were found filled, even to being distended, with broken-down blood-cells and methæmoglobin. This distention was often so great as to flatten the epithelium beyond recognition; elsewhere the epithelium was not altered in appearance.

A spectroscopic examination of the blood revealed the spectrum of methæmoglobin with great distinctness.

CASE II.—The second case was one which I did not see during life. On April 27th of this year, I made the autopsy of this patient at the request of his physician, Dr. W. A. Bartlett, of this city. To Dr. Bartlett I am indebted for the following history:

The patient was a strong, well-developed man, in active business, aged fifty-three. He considered himself in fair health until April 22d, although his family say that for several months he had not been quite well. He had complained of being easily fatigued, had had vague muscular pains, and had "looked badly." His face, they say, had been pale and waxy in appearance, and he had suffered from a "chronic throat trouble," for which he had long been using chlorate of potash. This he had used both as a gargle and as an internal medication. After his death his servant stated that he had been in the habit, for at least two years, of buying the drug "by the pound," and "that he had used a dozen of those pound-cans during the past year." The last can was purchased only a few days previous to his death, and of it only a little had been used. He was also in the habit of carrying in his pocket a small box of lozenges made of this drug, and it was usual with him to allow them to dissolve slowly in his mouth.

On April 22d, on which day he became really ill, so that he was unable to attend to his business, he felt chilly and feverish all day. He complained especially of sore throat and pain in the back, and is known to have used more chlorate of potash than usual. He passed a very restless night.

On April 23d he was first seen by his physician. Then his pharynx was slightly congested, and swallowing was painful. His temperature was 102°; his pulse, 100. There was very decided jaundice of skin and conjunctivæ. In the afternoon of the same day he vomited, and had several movements from his bowels. The matters vomited and passed per anum were not kept for the inspection of his physician, but were described by his family as having been of a very dark-green color, and as having contained blood. On the same day he passed about a half-pint of urine, which was black in color and untranslucent. His pulse then was imperceptible, he was restless, tossing about the bed, showing most of the symptoms manifested by a person who had suffered from a severe hemorrhage. At this time his color was a most peculiar and almost indescribable yellowish-gray, and he appeared like a man who was dying in collapse from loss of blood. The vomiting continued at intervals during the next twelve hours.

On April 24th he passed no urine at all, but his general condition seemed somewhat better. His temperature was normal, his pulse was of better character, and his strength somewhat restored. There was no more vomiting. His jaundice deepened somewhat. The mucous membrane of his mouth and pharynx was generally very pale, but here and there were to be seen areas of black discoloration. Suppression of urine continued till his death.

On April 25th he was very feeble. His pulse had become weak and thready. His temperature was normal. Vomiting did not recur. As he passed no urine, an attempt to purge him was made by giving him twenty grains of calomel, and subsequently one-fifth of a grain of elaterin. This medication did not cause his bowels to move.

On the next day, April 26th, he became steadily weaker, and decidedly drowsy. He could be easily roused during the early morning, however. His feebleness passed gradually into a condition of collapse, and he died comatose at 8 A.M.

I made the autopsy twenty-six hours after death.

The body was very decidedly jaundiced, and there was slight œdema of both lower extremities. Both pleural cavities contained very dark-colored serum. It was almost black in color, not transparent, and half a pint on each side. The pericardium contained the usual quantity of serum, but it was stained like that of the thorax. The heart was pale and flabby, and contained a large amount of fat in its muscular fibres; this was most distinct in the papillary muscles of the left ventricle. Besides these changes, it presented nothing of interest beyond the various degenerative changes of middle life. The lungs were moderately congested, and there was mucus in the bronchi. The spleen was large, at least six times as large as normal, and it was of firm consistency. Its cut surface was of very dark chocolate color, and it did not become lighter or arterial in hue on exposure to air. The kidneys had a granular surface, but were not distinctly atrophic. The markings of their cortices were not distinct. Their color throughout was of a dark chocolate hue, like that of the spleen. The stomach presented a somewhat thickened mucous membrane, but was otherwise unchanged. The intestines contained a large quantity of thick, dark-green material, which was of the consistency of a thick gruel. The liver was somewhat darkly stained, but less so than the kidneys. It was of normal size. The gall-bladder was filled with thick, very dark-green bile. The urinary bladder contained two ounces of urine, which was almost black in color, and closely resembled the dark-colored, untranslucent fluid which was found in the pleural cavities. The blood of the great vessels and heart was darker red than normal, and did not become at all arterial in color on exposure to air. It was in great part fluid. The microscopic examination of the organs was especially interesting. The kidneys showed very marked changes. The convoluted and straight tubules were very generally filled with dark-colored masses of altered hæmoglobin and broken-down red blood-cells. These masses were of irregular outline, and often appeared to overfill or distend the tubes, and in these situations the flattening of the epithelium was as plainly visible as in the other case. Occasionally tubes were seen only partially filled with similar material. The tubes often contained hyaline casts, but the changes seen in the parenchyma generally were but slight and of chronic character, and not related to his recent illness. The liver and spleen contained much altered hæmoglobin; in the former it was distinctly seen in the capillaries. The heart contained much fat in its muscle-cells. It was deposited in the form of fine granules, and very generally obscured their transverse striation, especially in the papillary muscles of the left ventricle.

MEDICINE AND MONEY.—Withal be good to the poor. You have them always with you. It is often cruel to accept pay from them. Be systematic in business, so that you will be able to give when and where it is required.—*St. Louis Med. Journal.*

CHOLERA INFANTUM AND THE WEATHER.

By T. CLARK MILLER, M.D.,
MASSILLON, O.

UNDER the head of cholera infantum it is becoming more and more the habit of physicians to group the diseases occurring in young children, during the season of high temperatures, which are characterized by impairment of digestion and assimilation and varying degrees of gastro-intestinal irritation.

The disease seems to be most prevalent in a belt running from east to west, between the thirty-eighth and forty-second parallels. The cholera type or phase of the disease is of short duration, but the disease proper, having been once established, is not likely to be fully recovered from so long as high temperatures prevail. After this new cases cease to appear, and the children affected begin to recover. They do not all, by any means, recover, for some have gone beyond that point from which complete recovery is possible; while others, in their debilitated and poorly nourished condition, succumb to the malign operation of other agencies and influences on constitutions which have lost, to a great extent, their powers of resistance, as well as those of recuperation.

This is not intended as an opinion, but as a statement of the general impression made on the minds of careful observers. Observation also justifies the belief that a continuance of high temperature, for a more or less definite period of six to ten days, is necessary to the development of the disease, in an epidemic form, in the early part of the hot season; while, as the season advances, the number of days of continued high temperature necessary to inaugurate new epidemic outbreaks becomes less.

This being true, it is not at all strange that unprofessional grandmothers, as well as physicians, have associated the disease with the continued high temperature as effect and cause, not ignoring the existence of co-operating causes, nor the varying degrees of susceptibility in children.

The painstaking and elaborate study of this disease, presented to the New York Academy of Medicine by Dr. A. Seibert, and published in THE MEDICAL RECORD of March 24, 1888, is a very valuable addition to the literature of the subject, and is especially interesting to me from the fact that for the past twenty years this summer disease has been a field of study in which I have bestowed considerable labor.

About ten years ago I made a somewhat careful statistical study of this disease on about the same line as Dr. Seibert's paper, only, however, using *mortality* statistics; the doctor's observations show that the morbidity curve is parallel to the mortality curve, so that one substantiates the other. My investigations took a somewhat wider range, geographically, including Boston, Philadelphia, Baltimore, Cincinnati, and Chicago as well as the metropolis. A part of the results of this work was presented, in the form of a paper, to the Northeastern Ohio Medical Association, at its meeting in August, 1878, and was published in the *American Journal of Obstetrics and Diseases of Women and Children*, April, 1879. From this paper I shall feel at liberty to quote at some length as I go along, such quotations being indicated by inverted commas.

I have been led to question very seriously whether the gastro-intestinal trouble is really the disease, and to incline very strongly to the opinion that the general system is profoundly affected, aside from, and independent of, the exhausting effects of the discharges from the stomach and bowels and the subsequent more or less active inflammatory conditions. "The disease is usually developed gradually, the child loses its vivacity, ceases to perspire, loses the desire for food, heat rash disappears, the skin becomes dry and hot, and the little sufferer is restless and irritable. The attack in its choleraic phase is often sudden, explosive, and may be fatal in a few hours; doubtless in many instances the organism is so profoundly affected that death comes speedily on, even without the occurrence of serious vomiting or purging. Recovery is also slow, and generally not complete until the summer ends. Although, of course, all choleraic features have disappeared from the case, yet to control the vomiting and purging is not, by any means, to restore the patient to health. This, of itself, suggests that the serous discharges are merely symptomatic, or at least not at all to be considered the sum-total of the disease.

"A second attack of the choleraic symptoms is to be looked for under much less provocation than the first; that is, those children who have passed through one attack yield much more readily to the influence of a recurrence of continued high temperature than does a healthy child, or one who has so far escaped, so that, whereas the first attack did not occur until after from six to ten days of continued high temperature, three to six days will be sufficient to precipitate a second attack, showing that the system had not regained its normal power of resistance, and that the disease was not fully recovered from, though the choleraic symptoms had subsided."

As to what constitutes *hot weather*, there would be all shades of opinion, no doubt; but it is generally believed, I think, by sanitarians, that during the winter an indoor temperature above, say, 72° F., is too high. If 75° or 80° be too high in the winter, in a hygienic sense, we may assume that it is a high temperature in the summer.

The air we breathe ought not to be above 72°; the demand of the surface of the body for a higher temperature must be met by clothing. However, the fact that the thermometer indicates 80° or 90° for a moment, or a few minutes, does not make a *hot day* so surely as when the mercury takes a long rest at a much lower point.

The all-important source of terrestrial heat is the sun. As its rays approach the perpendicular the ice disappears, the frost comes out of the ground, the grasses spring up, tender vegetable growths can live overnight out of doors, fruits mature, the earth becomes warm, in short, the heat of the sun is *cumulative*; it reaches into the night, through the night, over into the next day, and the climax of its power and effect is not reached for some days after its rays have begun to recede from the perpendicular.

This accounts for the high minimum temperatures of July. In the first week in August the rays strike the earth at such an angle that the residual heat begins to be lost, and the hot nights, or at least successive hot nights, cease to appear. I do not insist on calling these nights *hot*, but they are not cool enough. The child which passes the first week in August in vigorous health may be said to be, substantially, safe from the disease in question, because he is pretty sure of a chance to cool off. "The condition under which cholera infantum appears, and the only condition necessary to its development, is continued high temperature day and night—a mean thermometer above 75°, with small daily range. This high and slightly varying temperature, continued from six to ten days, will invariably, in our climate, bring cholera infantum (together with other bowel troubles, symptomatically more or less distinct, but pathologically akin), and the longer this condition of things continues the more numerous and the more intractable the cases become. This is as true in the country as in the city, though we are led to think, as we read the books, that this is a disease of the city especially. Deaths are registered, to be sure, and the books are made in the cities; but if the conditions above mentioned exist in the country, the disease appears there. Of course, not a great many cases, for the susceptible babies furnished by a single block in the city would outnumber those of two or three square miles in the country. Yet I am glad to admit that the conditions, for obvious reasons, are not so

likely to be present in the country; the contrast in point of green grass, shade, cool water, and moving air, is no less marked than is that in the percentage of mortality; and it is no more marked. Few, if any, recoveries will take place until the temperature falls; this fall is often attended by rain, but this does not seem to be essential, the fall of temperature alone being sufficient to bring about a better state of things (there being, apparently, no constant relation between barometric and hygrometric fluctuations and the rise and fall of the death-rate from this class of diseases). When the temperature falls cases improve and new cases cease to appear."

Infants may be affected at all seasons of the year by diseases having choleraic features; but it is very clear that these troubles, occurring in the cool or cold months, are not at all related, pathologically, to the summer disease under consideration.

In estimating the agency of milk, or any other single article of food, in the production or aggravation of this disease, or, in fact, of any disease, unless in an individual case, it would be interesting to know what percentage of the sufferers subsisted on the particular article of food in question. It is well known that milk will readily change at 60°, and certainly it will change no less readily at higher climatic temperatures. It will very often encounter a temperature much above 60° before it reaches the consumer, or, at any rate, before it is consumed, even when the minimum daily temperature is below 60°; yet summer complaint does not become epidemic.

"After all these considerations have been given their proper weight (and we do not wish to evade this), unless there is a succession of days of high temperature and small daily range, there is no cholera infantum; while, on the other hand, with a continued high temperature for several successive days, with but slight fall during the night, there is cholera infantum, and, in the natural course of things, there are no recoveries unless the temperature falls."

In the paper referred to above a number of tables were given to illustrate the constant relation which exists between thermal fluctuations and the mortality from the diseases under consideration. These are omitted here to avoid repetition, and I will add only one table showing the mortality from cholera infantum in the city of Baltimore, for each week, in the months from May to October inclusive, in the years 1879–87, with the mean of daily values of the thermometer for each week, and the maximum and minimum means of temperature for each week.

"In order to the construction of perfectly satisfactory tables for the illustration of this subject, it would be necessary, not only to have definite and uniform reports, naming disease and age of decedent, but a *daily* record of mean, maximum, and minimum thermometer. Weekly records are not altogether satisfactory, because the mean may be high for the week, and yet a low minimum may have been reached once or more, and even without this the time is short for the development of cholera infantum, and the following week may be more marked for its high mortality, though it may have so many *days* of low mean as to show a low *weekly* mean.

"A *monthly* record does not satisfy the requirements, from the fact that there may be two or even three weeks of low temperature, giving the month a low mean, and yet enough of days of high temperature to give the month a high mortality record from cholera infantum, or from a succession of hot days at the end of the month the cumulative effects show on the mortality records of the following month of perhaps low mean."

I am very sorry to seem to place myself in antagonism to high authority, and I certainly do not wish to provoke controversy. I do not think I fail in appreciation of the painstaking and admirable work of Dr. Seibert, but it is tremendously important to the profession and to humanity that we should arrive at correct views regarding a disease which, in our northern cities, causes, inside of four or five months, from three to eight per cent. of the total annual mortality.

I am thankful to Dr. Seibert for his valuable addition to tabulated facts bearing on this disease; but I believe his reasoning from these facts to be utterly fallacious and misleading, and, it seems to me, many of his conclusions are squarely in the teeth of his data. It is a subject of annually recurring and profound interest and importance. The learned discussion of the paper referred to, in the Academy of Medicine, is ample evidence that the subject is not exhausted, and it certainly cannot be said to be even threadbare, so long as it is possible for a great authority to call in question the superior mortality, from this disease, in July as compared with August.

ELECTRICITY IN GYNECOLOGY.

By F. E. BUNTS, M.D.,

CLEVELAND, O.

At a time when electricity is occupying such a prominent position in gynecology, it may not, perhaps, be out of place to make a few remarks concerning its use and practical application to gynecological diseases. In order to understand the application of electricity, it is absolutely essential that a knowledge of its rudimentary principles should first be obtained; and in order that confusion may not exist concerning the meaning of the various terms used, this knowledge should be obtained from some standard non-medical text-book.

It is seldom that physicians can converse upon electrical subjects without finding themselves at variance upon the significance of such terms as ohms, volts, electromotive force, resistance, quantity, strength, etc., and I shall venture to give a definition of some of these terms in order to make clear what I have to say.

An ohm is the unit of resistance.

A volt is the unit of electromotive force, and is a little less than the electromotive force of one Daniell cell.

An ampère is the unit of current, and is that current furnished by an electromotive force of one volt through one ohm of resistance.

Electromotive force is employed to denote that which moves or tends to move electricity from one place to another. It is usually abbreviated E. M. F. It is proportional to the difference of potential. "Just as in water-pipes a difference of level produces a pressure, and the pressure produces a flow so soon as the trap is turned on, so difference of potential produces electromotive force, and electromotive force sets up a current so soon as a circuit is completed for the electricity to flow through."

A milliampère is a thousandth of an ampère, and is the ordinary measure of current in gynecological electricity. It is not unusual to hear the strength of a current spoken of in volts or fractions of a volt, but by our definition this is manifestly incorrect.

It is, however, upon such terms as "strong," "great," and "intense" that we are most often stranded. Much confusion has arisen from the improper interpretation of these words, and it may lift a great weight from the minds of many if I quote, from such an excellent authority as Sylvanus P. Thompson, that these terms mean precisely the same thing; and further, "Formerly, before Ohm's law was properly understood, electricians used to talk about 'quantity currents,' or 'intensity currents,' . . . the terms were convenient, but should be avoided as misleading."

An understanding of Ohm's law will enable us to talk of currents without reference to quantity or intensity, and bring us to a realization of the fact that it is the *strength* and duration of the current upon which its electrolytic action depends, and not upon whether it is an "intensity current" or a "quantity current." Ohm's law is expressed by the formula current $\frac{(c) = \text{E. M. F. (in volts).}}{\text{Internal resistance in ohms} = \text{External resistance in ohms.}}$ Now, to determine our current, we must substitute the electromotive of our cells and their resistance, as well as the resistance of the conducting wires and the body. Practically, the resistance of the conducting wires, being usually very small, may be ignored. Suppose, for instance, we have a battery of 50 Daniell cells connected in circuit. The E. M. F. of one cell equals about 1.08 volts; internal resistance of each cell equals about 2 ohms. Amory gives the resistance of the body as from 1,000 to 12,000 ohms, depending upon the locality of the electrodes, their nature and size, and the condition of the skin. This estimate is obviously very vague, and, in my estimation, much larger than that met with in Apostoli's treatment of uterine fibroids. Suppose it to be 200 ohms, then we have for our current from 50 cells, current $= \frac{1.08 \times 50}{2 \times 50 + 200} = \frac{54}{300}$ ampères, or $\frac{54000}{300}$ milliampères $= 180$ milliampères, which is, in fact, the highest current which, under ordinary circumstances, I can get from my battery of fifty cells in the treatment of uterine fibroids.

I trust that this demonstration will not prove out of place, but be of service in shedding light upon the strength of currents we use.

I know that I am not orthodox when I say that, in my estimation, it does not make one particle of difference whether a "quantity current" or "intensity current," a "high-tension current" or a "low-tension current" be used, so long as our milliampère mètre shows us that we have registered the same number of milliampères in each case; and taking the invaluable milliampère mètre in connection with a clear comprehension of Ohm's law, we have a means of ridding ourselves forever of the incubus of an unintelligible nomenclature of currents.

It is easy to see how, before we had our milliampère mètre, we had such different effects from so-called "quantity currents" and "intensity currents;" but I apprehend it was due more to their capability of overcoming the resistance offered by the body than to any actual difference in their *quality;* and that, could we have registered their strengths, we should have found them producing exactly the same conditions in the human body when equal strengths were used.

It is an established fact that the quantity of any electrolyte decomposed by a current is directly proportional to the strength of the current, and also to its duration. Amory goes so far as to claim that we can obtain the same electrolytic result in human tissues from a weak current, employed for a long time, as we can from a strong current employed for a proportionately shorter time. If this be true, the application of electricity in Apostoli's method may be greatly modified; for, if the electrolytic action of 300 milliampères for five minutes was desired, and our battery furnished us with a current of but 100 milliampères, all that would be necessary would be to use this current for fifteen minutes instead of five, producing thus the same result with much less pain and much less inflammatory action which "may stimulate abnormal growths or cause dangerous inflammation of serous membranes."

According to Amory, there are four methods by which electricity may interfere with interstitial nutrition and destroy the life of the cells:

"1. By producing a true decomposition of the chemical compounds upon whose combination the integrity of the living structure depends.

"2. By interfering with the natural process of cell-segmentation. . . .

"3. By promoting a movement of the mass of fluid in the living tissues toward the negative electrode, and thus interfering with constructive metabolism. . . .

"4. The acid and alkaline reactions at the positive and negative electrode, respectively, from which a caustic action upon the tissues is effected through contact of these two different chemical reactions."

It is reasonable to suppose, arguing from analogy, in the action of electricity upon chemical compounds, that 1, 3, and 4 will vary directly as the strength and duration of the current; but as for 2, we must hesitate before we accept it, since, if we do, we can at once do away with our high currents, clay electrodes, pain, and danger. It is important, therefore, that further observations should be made concerning the comparative effects of high currents for short periods and low currents for long periods. While admitting the advantage which the establishment of this principle would give us in all cases where electrolytic action was desired, I am not prepared to accept it without further demonstration by means of actual measurement with the milliampère mètre. At the same time I have made it a rule, in such cases as have not been able to tolerate a strong current for a given time, to use a weaker one for such a length of time as will, in theory at least, give me the same electrolytic action as I desired to produce by my stronger current.

I desire to call attention to the value of galvanic currents of 20 milliampères strength in the treatment of cervical stenosis, by means of a graduated series of sounds fitted to screw into an insulated handle. In the few cases in which I have recently used it, I have met with very gratifying success. The treatment should be repeated twice a week, and last from five to ten minutes.

In membranous dysmenorrhœa strong galvanic currents are destined to hold a high position in uterine therapeutics. In a case of this character which came under my care, and in which an almost complete membrane was cast off at each menstrual period, accompanied by excruciating pain, I made use of a current of from 40 to 60 milliampères, using a platinum sound for the negative electrode. The treatment was continued twice a week for five weeks, and resulted in a complete and permanent cure of a diseased condition of which Dr. W. G. Wylie says, "A well-marked case usually continues as long as the patient menstruates."

The relief of uterine flexions by the combined use of tonics and intra-uterine applications of electricity is probably too well established to need any illustrative cases.

While the number of cures of fibroid tumors by Apostoli's method of treatment is not as great as had been hoped for, yet the relief from the distressing symptoms so frequently accompanying these tumors is sufficient of itself to establish it at once as an invaluable agent in their treatment.

I wish to allude to but one case in detail. The patient was suffering from a large fibroid, accompanied by profuse hemorrhage, retention of urine, constipation, and neuralgia of the lower extremities. I had not at that time become acquainted with Apostoli's method, but decided to use galvanism upon her, and selected the *negative* pole for the uterine electrode—for no better reason than that the positive pole would pain the abdomen less, and from a belief that there would be "a movement of the mass of fluid in the living tissue toward the negative electrode." Having at that time no milliampère mètre, I made the current as strong as the patient could possibly tolerate it, with the result of completely checking the hemorrhage by the third treatment, and in a short time her other uncomfortable symptoms entirely disappeared. Three months after she had ceased treatment she applied to me again, with a return of her hemorrhages so profuse as to be alarming. I had during this time read Apostoli's work, secured an Edelmann's milliampère mètre, and Apostoli's platinum sound. Imbued with the idea that the *positive* pole was the antihemorrhagic pole, I assured her I could check the flow without any trouble, and gave her 180 milliampères for six minutes, with the positive electrode in the uterus. This I repeated at intervals of three days, for four treatments, without any perceptible effect. The patient becoming discouraged, I decided to return to my former line of treatment, and used the negative pole for the uterus with a current of 150 milliampères. When she came to my office the following week the flow had ceased entirely, and there has thus far been no recurrence, a period of about five months.

It may be a "post hoc" argument to say that the negative pole was the proper one to have used, but the relief was so marked in both instances that I relate the case in hopes that it may prove of interest, if not of use.

Before closing, I should like to consider, briefly, the technique of Apostoli's method. The greatest obstacle is the obtaining of an abdominal electrode which shall diffuse the current equably over a large surface; and, after trying various means, I have succeeded best by using a flexible copper plate, 10 x 9 inches, rounded at the corners, and covered with gauze and clay kept moistened, and laid upon ten or twelve layers of lint moistened in warm water and spread over the abdomen. I also have a smaller plate made which is more convenient when weaker currents are to be used. In regard to the uterine electrode, I think that the platinum sound is by far the best for general use. One great advantage is that we can use it in connection with the positive pole without its becoming oxidized and lacerating the lining of the uterus during its removal. In my estimation the insulator for this sound should be, preferably, a simple glass tube slightly tapering at its end, and sufficiently larger than the sound to allow of the free escape of the products of decomposition, which are particularly abundant when the negative pole is used. This free escape not only lessens the possible risk of septic absorption, but, in my observation, lessens to a considerable extent the pains which sometimes supervene upon this treatment, and which, I imagine, may, to a greater or less extent, be attributed to the efforts of the uterus to rid itself of the foreign substance within its cavity.

ABDOMINAL NEUROSIS AND EXPLORATORY LAPAROTOMY IN THE MALE, WITH CASES.

By B. E. HADRA, M.D.,

GALVESTON, TEX.

One of the great gains of modern surgery is, as is well known, safety and ease of access to the abdominal organs by laparotomy, not only as a curative, but also as a diagnostic procedure. But it seems to me that the gynecologist makes a bolder and more extensive use of exploratory laparotomy than the general surgeon. Is it due to the greater readiness with which women submit to surgical treatment? Considering even that from the nature of things there must oftener be a good cause to open the abdominal cavity in the female, because her generative organs are, to a great extent, situated therein, still, giving to this fact its full due, the disproportion between laparotomies in females and those in males seems to be remarkably great. Perhaps the gynecologist is more inclined to undertake the operation, even without absolute necessity, because laparotomies represent the roses and camellias in his surgical bouquet, and because his standing in the profession and before the laity is greatly dependent upon the number of such operations performed. On the other hand, the general surgeon observes stricter indications and acts less on mere suppositions and probabilities. His fame, too, has so many other fields in which it can be sown and harvested, that he is not so much dependent upon this limited crop. Yet there is no good reason for him to be altogether outdone by the gynecologist. Before all, he should do away with the vague diagnosis of abdominal neurosis.

I venture to say that only an extremely small percentage of such ailments will turn out to be purely functional; that is, not showing palpable alterations of the tissues. The great majority will be caused by visible changes, and of them again a great number will be amenable to surgical adjustment. The inference, then, to be drawn, if these premises are correct, is, that to exploratory laparotomy will have to be given a wider range by the general surgeon than it has at present. Persistent, chronic, undiagnosticable abdominal troubles should be subjected to the operation, and no surgeon should feel that he had arrived at a diagnostic terminus by pronouncing a case to be neurosis of the plexus solaris, or of any other nervous structure, by general outward signs. It is from such considerations that I offer three cases, of whom only the last was subjected to laparotomy, while the two others were equally proper subjects, and most probably would have been benefited by more accurate information, obtained by anatomical diagnosis and corresponding operation.

Case I.—A German tinsmith, about twenty-five years of age, consulted me in 1870 on account of the most fearful neuralgic attacks, starting about two inches above the right Poupart's ligament, deep down in the abdominal cavity. They came on daily, and even several times a day, when the unfortunate man would roll on the ground from pain while perfectly conscious. Nothing could be made out to throw the least light upon his case. It was plainly not epilepsy. The condition of the bowels, testicles, and all neighboring organs was seemingly normal.

The patient, an extraordinarily intelligent man, had for several years wandered, making his way by working, from one centre of medical wisdom to the other; he had consulted all German, French, and English authorities; was finally sent to the United States, and from the North to the South, expecting relief from climatic changes. He had a book, and quite a thick one, with notes, opinions, and prescriptions, collected from all over the world. There was no anti-neuralgia remedy untried. I, of course, could not do more for him than all the combined science of four nations. He, though, was always promptly relieved by the hypodermic use of morphine. After some months he passed from my observation, and I cannot say what has become of him. In such a case it would not only be proper, but our duty, "to go in and see."

Case II.—T——, a German, very intelligent, began complaining occasionally of indefinite acute pain in the abdomen, when at the age of thirty-four. In 1876 he partook, during a protracted excursion, very hastily, of a couple of glasses of ice-cold beer, and swallowed with avidity a large quantity of meat. A few hours later he was taken with severe colic.

He slowly improved, though from time to time exacerbations of colicky pain ensued. Some weeks afterward, a lump of undigested food—meat, as proven by the microscope—as large as a small fist, was passed per anum. He recovered to such an extent that he considered himself cured. Then indistinct pain set in again, originating in the vicinity of the navel and ranging up into the thorax, "taking the breath from him." The attacks seemed to have some connection with meals and intestinal movements, though there was no constant and definite dependency. Laxatives, stomachics, digestives, etc., were useless, hypodermic injections of morphine affording the only relief. There was vomiting occasionally, mostly after abuse of morphine, which was gradually raised to eight grains a day. Blood was never vomited or passed per anum. There were intervals of perfect rest, lasting even for two months, but growing shorter. The patient was in the hands of an eminent practitioner, who considered the case purely neurotic. In 1879 I saw the patient the first time. Nothing could be made out objectively, though everything pointed to intestinal trouble.

I thought of an invagination, healed with circular stricture, but the statement in regard to the lump which had passed from him was too definitely adverse to such an assumption. T—— grew gradually worse, partly from the excessive suffering, but mostly from morphinism.

Laparotomy was proposed, but refused; the former attendant, who was still in consultation, insisting upon the neurotic nature of the disease. T—— finally died in 1882, having suffered fully six years from his most deplorable condition.

Post-mortem examination: Very emaciated body, covered with abscesses and marks of hypodermic injections. All organs seemingly healthy. An examination of the duodenum revealed, finally, the cause of the suffering. It was twisted about one-half of its circumference around its long axis, and fastened by fresh-looking inflammatory adhesions to the pancreas, so that it could, to some extent, be untwisted, but not entirely so. (I will mention that due attention was given to the physiological attachment of the duodenum to the pancreas.) Obviously the passing chyme had always to overcome this valve-like impediment before it could pass, and had to drag on the adhesions.

Case III.—T. G. M——, American, inmate of Confederate Home at Austin, fifty years of age, recollects having had spells of spasmodic pain, situated on the left side of the abdomen, near, and a little below, the umbilicus, since his sixteenth year, for which he knew no cause. The attacks were best relieved by a bent position, steady pressure, and warm applications.

He suffered in his twenty-fourth year from chills and fever, and severe attacks of pain following each chill. He suffered occasionally from indigestion. He served in the Civil War, and felt relatively well until a spell of dysentery set in, when the attacks became as severe as ever before. He then got steadily worse, the attacks becoming more frequent and uncontrollable, until he was rendered a perfect invalid, not able to support himself. In 1880, without any obvious cause, he had for nearly six months a painless interval. In January, 1888, when I saw him the first time, he presented the facies of protracted suffering: a sallow complexion, much like a cancerous subject; complained of pain, coming on several times a day, not periodical, but worse in the morning and daytime than in the evening, and worse in wet and hot weather. The pain was situated to the left of the umbilicus, radiating thence through the whole abdomen. He was not able to be up except for a short time. There was no fever; the bowels were sluggish, but easily regulated, and the appetite was fair. On pressure over the seat of pain, the patient perhaps was more sensitive than he would be under natural conditions. Repeated palpations sometimes seemed to reveal a tumor; at other times I could not detect anything. In short, there was nothing upon which to base a positive diagnosis. The patient, believing that internal and local medication had been exhausted by the many physicians who had tended to him, and having already been prepared by some of them to an exploratory laparotomy, asked to have it performed. There was, of course, no reason to refuse his request. I may state that this case had also been diagnosticated as neurosis.

On February 18th, in the presence and with the assistance of Drs. Bennett, F. McLaughlin, Swearingen, and Tyner, all of Austin, the abdomen was opened, beginning the incision about two inches below the umbilicus, and carrying it around on the left side, upward, for a distance of about four inches in all.

Nothing abnormal could be detected, even after examining the omentum and the bowels outside of the wound. I was going to close the opening, when I discovered a sharp transverse ridge in the parietal peritoneum, about one inch above the upper end of the incision, and on closer examination it was found that the omentum was adherent to this ridge over a surface about equal to that of a silver dime. The adhesion was broken up and the ridge incised twice, so as to undo the contraction, in case it should be the cause of the trouble. This band was so tense that it took considerable force to sever it, and its giving way could be heard as a loud crack by the by-standers. There was little or nothing remarkable about the other features of the operation. The patient made an uninterrupted recovery, and for two weeks was perfectly free from pain. After this time he began to suffer slightly. I was afraid the old adhesions would form again, and censured myself for not having exsected the ulcerated spot in the omentum and then sewn it up. But whether it was due to antipyrine, which was taken in five-grain doses three times a day, or not, the pain never exceeded a kind of burning, and at present the patient is able to walk two or three miles at a time, feeling pleased with his condition. His complexion and general health have greatly improved.

"The American Dematologist" is the name of a new journal published in Indianapolis, the object of which is sufficiently indicated by its title.

Clinical Department.

REPORT OF A CASE IN WHICH AN ATOMIZER-TIP WAS FORCED DOWN A PATIENT'S THROAT, DISLODGED AND SWALLOWED, AND FINALLY PASSED PER RECTUM.

By J. F. HOFHEIMER, M.D.,

NEW YORK.

Having occasion recently to order a patient of mine to use a hand ball-atomizer in his throat, he purchased one of his druggist. A few evenings later, while spraying his throat, he noticed something "give way," and felt a choking sensation. He immediately threw himself over a chair, head downward, and succeeded in "coughing it out of his windpipe," but "before he could get it out of his mouth it went down into his stomach, and he could feel it all the way down." Becoming much alarmed, he immediately came to my office, where, on examining his throat with the laryngoscope, I detected a denuded surface in the pharynx, which, when I touched it, the patient said felt like the place where the spray-tip had struck. There being no signs of a foreign body having found lodgement in either the larynx or œsophagus, the patient was advised to eat plenty of solid food, and indulge but sparingly in liquids, and to keep the bowels constipated for a few days. Two days afterward the young man passed a large lump of fecal matter, in the midst of which the tip was found. The tip was one intended for the nose, but my patient used it for his throat, and he was no doubt lucky in his choice, for the other two tips were much smaller and could easily have lodged in his larynx.

There are a few lessons to be drawn from this case. The majority of atomizers sold by druggists and instrument-dealers are defective, inasmuch as the tips slip, instead of screwing, on the tube. These tips are of various sizes and shapes, and have a minute opening at the distal end. Now, if this opening is obstructed, one of three things is liable to happen: The cork is forced out of the bottle, the rubber-tube becomes forced from its connection to the spray, or the small tip is blown off with considerable force. I have experimented with an atomizer, and found the force was sufficient to blow the tip across a small room with great velocity.

On examining the tips of various forms of sprays, it was found that only one maker of spray-apparatuses with hard rubber fittings had tips which screwed on. It seems an easy matter for a screw thread to be placed upon the tip and stem of a spray-tube, yet the absence of such a small item may cost a life or necessitate a severe operation. Indeed, the tip used by this patient was rather larger than usual, and to that partly I attribute the fact that it did not enter the trachea.

POISONING BY KEROSENE.

By. K. A. NORDERLING, M.D.,

ROCKFORD, ILL.

I was called on June 29th to see a child, eleven months old, who had swallowed an unknown quantity of kerosene. I arrived about ten minutes after the accident had occurred, and found the little patient in the following condition: There was drowsiness, which was on the increase; and she was feverish; pulse, 150, weak; respiration, 40; face and neck covered with perspiration, extremities cold. Her mother, when the accident occurred, hearing her cry, ran to her help, and found her in a very cyanotic condition, with kerosene vapor coming from her mouth; all she did was to sprinkle water in her face. Upon my arrival I immediately administered all the milk she could drink, and then wine of ipecac, which in five minutes brought on vomiting. On the vomited matter could be easily seen the kerosene floating on the top like fat globules in a soup-dish. Before leaving, I told the mother to give her all the milk she could drink, and also to give her castor-oil. Next morning the mother told me that the child had had one movement of the bowels in the morning, but neither that nor the urine which was passed all right had any odor of kerosene. She had been very restless during the night, coughed some, and moaning between times. At noon the fever was high, 104° F. in the axilla; pulse weak, 150; still in a drowsy condition. In the evening of the same day the patient was nearly without fever, and looking bright, and the next morning she was perfectly well. I think this is worthy of being recorded, as I have never heard nor read of a case of kerosene-poisoning in so young a child.

NERVOUSNESS PRODUCED BY OBSTRUCTION OF THE NARES, WITH REPORTS OF CASES.

By E. HARRISON GRIFFIN, M.D.,

ATTENDING SURGEON OF THROAT AND NOSE DEPARTMENT OF BELLEVUE HOSPITAL OUT-DOOR POOR, NEW YORK.

THREE years ago A——, aged fifteen, female, applied to me, complaining of an obstruction of her nose. The left side had been closed for years, and through the other she could breathe at times, but never freely. The left nostril was considerably swollen; she complained of attacks of pain on this side, and there was a constant and copious discharge of pus from both portions of the nose. Her mother told me that the patient snored loudly during the night, and at times, once or twice a week, would have a slight convulsion. The convulsions she had as long as she had the nose trouble. From the description of the attacks I diagnosed them as epileptic. At this time I saw no distinct connection between the occlusion of the nose and the convulsions. The examination of the left nostril showed it to be almost completely closed, while the septum was greatly deflected toward the right side. In passing the probe through the left nose the end struck against something hard and grating. I gave the patient a few whiffs of chloroform, and with a slender pair of forceps dislodged a shoe-button, which had become encrusted with the saline portions of the serum, and formed the nucleus of a rhinolith. The calculus was the size of a hazelnut.

Further inquiry elicited the fact that she had put the button in her nose six years previous, and had been afraid to tell her parents about it. She had tried to get it out, but had been unsuccessful. The month previous to the operation she had had five convulsions. After the removal of the button, the convulsions ceased entirely. I watched the case six months, and gave no medicine whatever.

CASE II.—Lately I have operated on a case of total obstruction of both nares, which had existed for twenty years, by gelatinous polypi. The patient is a large-framed Englishman, and one whose appearance would indicate that he was free from nervousness. He told me that, up to the age of twenty-five years, he did not know what it was to be nervous. He had lived an out-door life, and had always enjoyed the best health. At this period the polypi had made their appearance. They grew until the nose was completely closed, and in damp weather one or two could be seen below the lower margin of the nose. He had now a bad memory, although previous to the growth of the polypi his memory had been excellent. At times, when compelled to wait in my receiving-room, while I was busy with another patient, he would grow exceedingly nervous, and when I was ready to see him, his hands would be covered with a profuse perspiration. He knew that the operation was painless, but he could not control his feelings. The same thing had occurred to him again and again under different circumstances. The least little change from the daily routine of his life would make him nervous. I operated upon the polypi, and removed fully a hundred. Two days after I had freed the nose so that the patient could breathe through it, the nervousness had diminished perceptibly, although I was working upon smaller polypi higher up in the organ. When I discharged him, the nervousness had almost completely disappeared. He could now meet friends without feeling the extreme reserve that he had had previous to the operation.

CASE III.—C——, female, married, aged thirty-four, has been troubled with polypi for the last ten years. She had been operated upon repeatedly by different surgeons before she applied to me, four years ago. During this time I have removed fully three hundred polypi at different sittings. When her nose is free, to use her own expression, she feels happy, and can go to see her friends, but when her nose becomes stopped up she is nervous and dejected, and wants to keep away from everybody. An operation makes the greatest change in this person's disposition. She is naturally of a lively temperament, but when her nose gets obstructed she is blue and nervous. These symptoms disappear entirely after her nose is freed, but return the moment the nostril is again obstructed.

I do not think that every case of occlusion of the nares will give rise to nervousness, yet there are cases where a foreign body in this organ sets up a reflex action, and a cure of the trouble is only obtained by an examination of the nose and the removal of the obstructing element.

DEATH FROM FRIGHT (?).

By F. H. LESTER, M.D.,

SKANEATELES, N. Y.

THE following case, to me obscure and remarkable, occurred in my practice, and was observed by an able physician from an adjoining city, who expressed as doubtful an opinion I had previously entertained. A young man, nineteen years of age, had croupous pneumonia, which ran a regular course, giving typical symptoms and terminating by crisis on the evening of the seventh day from the initial chill. For two days the temperature remained normal, the appetite had returned, and the pulse was full and soft at eighty beats per minute. The young man I left in this condition forty-eight hours after the termination of the crisis. Twelve hours later I was summoned in haste, the messenger declaring my patient was choking to death. I lost no time in going to his home, where I found a large number of excited friends and relatives congregated. The patient, much excited, was gasping and struggling, his face turgid, his eyes staring, while his body was covered with a profuse perspiration. His temperature I found still normal, but his pulse was 120. After suppressing the noise and excitement, and clearing the room of unduly demonstrative persons, I essayed to quiet the patient, and so far succeeded that in a few moments from my arrival he breathed naturally, and his pulse soon fell to its natural condition, when, feeling reassured myself, I encouraged the patient not to become again so needlessly alarmed, and left the house. The next morning, however, I was again summoned, and the previously described scene was re-enacted. Succeeding this attack there was a rise of temperature to the extent of one degree, and the pulse beat one hundred and twenty-five times a minute. This time the patient declared his inability to swallow. Thoroughly aroused I instituted the most careful examination, but could find no adequate cause for such formidable symptoms. The patient expressed himself as suffering no pain, while his appearance gave indication of his suffering intensely from fright and apprehension, as he trembled violently. I succeeded again in calming his fears to the extent that I induced him to drink a glass of milk and eat a dry cracker, both of which he swallowed without marked voluntary effort, though he immediately afterward positively declared his inability to swallow anything, his father and mother curiously concurring with him in his statements, and exhibiting the greatest alarm. Thus the case proceeded, the patient taking food when I made my visits, sometimes without effort, at other times after more or less trouble; but very rarely could his father or mother, who were his constant attendants, induce him to take the least food or drink, and always seemed to alarm him by their entreaties. His temperature gradually rose, in spite of liberal doses of antifebrine, his pulse keeping pace with the rise of temperature. He secured no sleep, sweat profusely, and became delirious at the end of the seventh day; his pupils were dilated, his facial muscles twitched convulsively, he tossed restlessly about the bed, and finally died on the ninth day from the crisis of the pneumonia, his temperature having reached 106° F., his pulse 200, his pupils being widely dilated, and the whole muscular system in excessive jactitation.

I am confident the pneumonia resolved. I am sure there was was no empyema. The bowels and kidneys performed their functions naturally and fully. The patient did not complain of pain in the head. There was no disturbance of vision or of speech. There was no evidence of pharyngeal paralysis by ocular inspection. I always succeeded in inducing him to swallow after his parents had utterly failed. With me he seemed composed; alone with his parents, highly excited. I was unable to secure sleep or to reduce his temperature with medicine, given to the fullest extent consistent with safety. I have no definite conception of the primary cause of these formidable symptoms which resulted in death. But were it not for the fear of being considered foolishly credulous in the theory of the great mastery of the emotions over the body, and especially of the powerfully depressing and dangerous effects of fear, I should ascribe the death of this young man to mental causes acting upon an already susceptible and debilitated physical organism. I would add, in extenuation of my credulity, that a brother of my patient had died some time previously of croup, and that to this brother my patient often referred during his sickness.

A CURIOUS PHENOMENON OCCURRING DURING THE AMPUTATION OF AN ARM UNDER PROFOUND ANÆSTHESIA.

By W. G. M. SEIPLE, M.D.,

LEHIGHTON, PA.

William S——, aged forty-eight, railroad employé, was thrown while stepping from a moving train, and had his left arm, above the elbow, crushed to a pulp, necessitating amputation at the junction of the upper and middle third of the humerus, which was immediately performed by me, assisted by Dr. C. T. Horn and Dr. Sittler. After having removed the arm, and while taking up the arteries, I noticed a protrusion of the internal cutaneous nerve, about three-fourths of an inch, and as I always remove an extra portion of the nerves, which I may notice protruding, to prevent the liability of their being involved in the cicatrix, I grasped the nerve with forceps. As quick as a flash there was contraction of the portions of the muscles remaining, drawing them all up tightly into the axilla, leaving the bare bone protruding about three inches. The contractions were so firm and so quick that my tourniquet dropped off and left me without any protection as to hemorrhage. But after hastily examining the stump, I found the contractions so firm that not a drop of blood escaped. And now, how to get all this in position again. After a moment's hesitation, I had an assistant compress the subclavian, while I firmly grasped the shoulder with both hands, and by powerful pressure backward and suddenly bringing both hands forward, the parts sprang back into their proper position again. I immediately looked for the brachial artery to tie. I did not find it in its usual position; while looking, it gave a great spurt, when I found it on the under and outer side of the stump. After it had spurted the second time I succeeded in catching it with an artery clamp, and had an assistant tie it. No further trouble followed, and the wound healed kindly in about ten days under strict antisepsis. My impression and teachings so far have been that sensation being deadened by anæsthesia (in this case under thorough anæsthesia), reflex motion was also held in abeyance. Yet this case seems to prove the contrary. I would be pleased to have some of my professional brethren enlighten me concerning this peculiar condition. In all my researches I have not found a similar case on record.

HYSTERICAL SPASM OF THE ŒSOPHAGUS IN A YOUNG CHILD.

Dr. B. D. Foster, of Chicago, sends the following communication: "I was called one day in great haste to see Mary C——, ten years of age, who was said to be choking to death, and found her complaining of great pain in her throat, which she was grasping and begging her mother to rub for her. The mother, attributing the trouble to "a worm in her throat," was vainly endeavoring to pour down a dose of Jayne's vermifuge. The child was unable to swallow, the fluid regurgitating into a handkerchief held in front of her mouth. I immediately administered an hypodermic injection of morphinæ sulph., gr. one-sixteenth. Although complaining bitterly of the pain induced by the fluid being forced beneath the skin, her face immediately assumed a happy expression, and she laughingly declared she was cured the instant the needle was withdrawn, and, obviously, before the solution could have been absorbed. In a few minutes she was laughing and playing in her usual health. The history showed that her mother had been subject to various neuroses (supposed to be hysterical), and that two other relatives were idiotic or imbecile. I diagnosed hysterical spasm of the œsophagus. The youthfulness of this subject, and the immediate relief afforded by the prick of a needle, are not entirely devoid of interest."

Polyuria following Fracture of the Base of the Skull.—A man, aged thirty-six years, from a fall down stairs sustained fracture of the base of the skull. At the end of a fortnight he was so far recovered that the original symptoms were no longer noticed. The only complaints of the patient were deafness on the left side and occasional pain on the right side of the occiput. Polyuria was now noticed. Sp. gr. 1.010; no sugar or albumen. In the course of the following week the quantity of urine gradually fell to the normal quantity. The patient died of pulmonary disease about ten weeks later. The only noticeable lesion of the bones was a darkish line of from three to four lines in length in the posterior cranial fossa. Corresponding to this the dura mater was covered with a thin yellow deposit which, to the extent of the mark, was adherent to the nervous substance. Nothing abnormal besides this was seen on the brain, nor in any other organ.—*Provincial Medical Journal.*

Typhoid Fever has, upon the whole, diminished both relatively and absolutely. In 1886 the percentage of deaths from typhoid fever to deaths from all causes was 2.15; in the year of greatest prevalence, within a period of twenty years—1872—the percentage of deaths from typhoid to deaths from all causes was 4.86 and the death-rate per 10,000 living was 11.1. The diminution in the death-rate from this disease has been especially marked in cities with new water-supplies and good systems of sewers. The death-rate from this cause is substantially unchanged in the small country-towns. The death-rates from typhoid fever per 10,000 living, in census years 1865–1885, have been for the State: 1865, 13.4; 1870, 9.1; 1875, 6.4; 1880, 4.9; 1885, 3.9.—*Dr. Henry P. Walcott.*

Progress of Medical Science.

The Guiding Principles of Treatment in Excessive Corpulence.—Dr. George H. Rohe has published a paper in which he says that the corpulency of alcohol and beer drinkers is well known. It is likely that the depression of nervous excitability, due to the constant use of alcohol, is partly responsible for the fat-accumulation, although the alcohol in ardent spirits, and in the case of beer the carbo-hydrates additionally present, acting as respiratory food, save a portion of the fat in the food from oxidation and permit its deposit as fat-tissue. The Banting diet consists in a large excess of proteids, and great diminution, almost to extinction from the bill of fare, of fat and carbo-hydrates. On the theory that proteids alone are muscle-builders, while fats and carbohydrates are fat-forming foods, the Banting diet was correct; but the evils of a strict adherence to it were manifest before the recent physiological researches demonstrated the fallacies of the theory. There can be no doubt that Bantingism will reduce excessive fatness, but it also decreases the proteid constituents of the tissues, and may thus cause dangerous and even fatal consequences. It is frequently impossible to arrest the rapid waste of muscular tissue under the Banting diet, and the individual rapidly declines in health, even if the diet is withdrawn and the patient put on liberal allowance.

On account of the evil results which were frequently noticed as following the strict Banting diet, this has been modified in various ways. Vogel, who introduced the method in Germany, allowed a larger proportion of carbohydrates, while Immermann proposes to interrupt the treatment occasionally, and allow the patients to resume their habitual diet for a period. On the other hand, Cantani, the eminent Italian clinician, insists even more strongly than Banting upon the rigid exclusion of fats and carbohydrates. Beer, spirits, and the stronger wines are restricted or excluded from all dietaries for corpulence. Light acid wines are alone allowed.

In the last five years, two new methods, deviating in a rational direction from Bantingism, have attracted the attention of the profession. The first is that of Professor Ebstein, of Göttingen, who proposes a reduction of proteids and carbo-hydrates and an increase of fat. The philosophical reasoning of Ebstein claims careful consideration, since he bases it upon acknowledged physiological facts. He claims that less fat is deposited if there is much fat in the food than if the food contained an equivalent quantity of carbo-hydrates. Practical experience sustains this claim, as well as the further one that a smaller proportion of proteids suffices than is generally assumed. But an important point insisted upon by Ebstein is usually overlooked by his followers, namely, that active muscular exercise assists in the destruction of fats.

Oertel's method, which has also many earnest advocates, approaches, in its dietetic prescriptions, very closely the Banting system, as will be shown presently by a comparison of the different classes of food-materials in the various plans; but an important element in Oertel's regimen is the extremely small quantity of fluids permitted. This is not original with Oertel, as Dancel had already, in 1863, insisted upon its importance.

Professor Kisch, of Prague, who is resident physician at the famous sulphate-of-soda springs of Marienbad, has had a very large experience in the treatment of corpulence. He prescribes the waters (which act as a purgative), advises active exercise, and regulates the diet. Doubtless, good results follow this treatment, for it is based upon rational principles. The treatment by cold baths and exercise is also successfully applied for the relief of this condition by Winternitz, of Vienna.

Directly contrary to the advice of Oertel to reduce the fluid allowance of corpulent patients, Sée, of Paris, largely increases it. "Let your patients drink—drink all the time," is the advice he gives. He thinks tea is the best beverage, and that it should be consumed in large quantities. This practice is based upon the fact that free drinking of water promotes tissue-metabolism, and hence increases the oxidation of the fat, as pointed out by Landois.

There is abundant testimony that all these methods are efficient for the reduction of corpulence. For comparison, the following calculations of the amounts of the various food-stuffs in the Banting, Ebstein, and Oertel diets are given :

	Banting.	Ebstein.	Oertel.
	Grms.	Grms.	Grms.
Proteids....................	170–180	105	156–170
Fats........................	7.5	60–100	22–43
Carbo-hydrates............	80–85	45–50	71–114

Landois recommends a gradual and equable reduction of the entire bill of fare, with active exercise in the open air, purgation, cool bathing, stimulation of the skin, restricted hours of sleep, light clothing, and free consumption of liquids. There is reason to believe that such a regimen is more efficient and safer, even if not so rapid in its action, than a plan which depends principally upon the withdrawal of one or other class of food-materials.—*Philadelphia Medical Times.*

Syphilitic Conjunctivitis.—The Vienna correspondent of *The British Medical Journal* writes that at a recent meeting of the Royal Society of Physicians of Buda-Pesth, Dr. Goldzieher made a communication on conjunctivitis syphilitica. Syphilitic affections of the eyelids had to be divided into three classes, namely, primary lesion (initial sclerosis), exanthem, and gumma. Discussing the various pathological conditions in syphilis of the eyelids, he said that the symptoms of diffuse syphilitic conjunctivitis had not yet been described as a whole. He related two cases which showed that there really existed a sort of granular ophthalmia which was due to syphilis. The first case was that of a man, aged thirty-two, who had contracted syphilis six years before, and had suffered from chronic iritis since that date, so that iridectomy had to be performed. For the last few months an inflammation of the conjunctiva had supervened, which had been treated for a long time. On his admission into the hospital, erythema and diffuse swelling of the eyelids, with the formation of granulations in the mucous membrane, were found; besides this, there was swelling of the lymphatic glands in the region of the ear and the neck. After energetic treatment by mercurial inunctions for four weeks, the conjunctiva regained its normal appearance, and the patient was discharged cured. The second case was that of a man, aged twenty-six, who had contracted syphilis two years previously. Six months before his admission into the hospital he was attacked with conjunctivitis in the left eye, and was, like the first patient, treated without success by applications of the nitrate of silver, sulphate of copper, etc. He presented exactly the same changes in the conjunctiva as the first case, and, moreover, keratitis profunda, iridochoroditis, and lymphadenitis universalis. After an anti-syphilitic course of treatment, he was also quite cured. Dr. Goldzieher remarked that similar changes of the conjunctiva were observed in syphilitic inflammation of the tarsal cartilage. As the conjunctiva possessed a layer of adenoid tissue, and the infiltration referred to above was only to be looked upon as a follicular vegetation of this layer, the morbid process above described had, therefore, from the anatomo-pathological standpoint, to be considered as being identical with syphilitic lymphadenitis.

Empyema of the Gall-bladder and its Surgical Treatment.—Dr. Hirschberg has recorded a case of empyema of the gall-bladder occurring in a female, aged forty four. The patient was operated upon with successful result. In the remarks on the case the author finds that in most cases of empyema, or dropsy of the gall-bladder, the appearance of any tumor has been preceded for years by attacks resembling biliary colic, but in most cases there was absence of jaundice. This absence of jaundice is explained by the fact that the cystic is narrower than the common duct, and the most severe attacks of colic point to a stone fixed in the cystic duct. The milder attacks, with jaundice, point to a stone fixed in the common duct, or its passage through the same. Patients complain for a long time of a dull pain in the right hypochondrium. Fever may be entirely absent. The urine is free from pus, if pyonephrosis does not also exist. Physical examination of the abdomen discovers a smooth, tense, elastic tumor, movable from side to side, diminishing in size toward the liver. It is not connected with the abdominal parietes. A coil of intestine may lie over the tumor, which is painful to pressure. The patients complain of pain in the left shoulder. Puncture gives a purulent fluid containing biliary constituents. Particularly is the diagnosis to be made from pyonephrosis. It has been most often mistaken for the latter condition. Inasmuch as operative interference is indicated in both diseases, we will perhaps find our way best by an exploratory incision made, according to the author, in a transverse direction. Operative procedure is indicated in (*a*) chronic lithiasis, and (*b*) retention cysts of the gall-bladder, due to stoppage of the cystic duct by a stone. Especially is empyema included here. Operation is not advisable at a time when a calculus is supposed to be passing the common duct; the time should be chosen when it has passed into the intestine. The continued menace to life by a lasting closure of the common duct by stone may be warded off by a fistula of the gall-bladder. If in the latter case the constant loss of bile should so affect the economy as to threaten life, cholecystoenterostomy is a justifiable operation. Cholecystectomy is indicated in long-standing formation of biliary calculi. It here stands as a rival to cystotomy.—*Annals of Surgery.*

EXTROVERSION OF THE BLADDER.—At a recent meeting of the Royal Medical and Chirurgical Society (*The Lancet*) Mr. G. H. Makins contributed a paper on "Extroversion of the Bladder treated by Preliminary Division of the Sacro-iliac Synchondroses." The following is an abstract: The patient was a male child, aged five. An attempt to raise a flap after Thiersch's method had failed three years previously. On the second admission a cicatrix on the left side of the extroverted bladder marked the position of the unsuccessful flap, and prevented any considerable shifting of the skin on that side. On November 29, 1886, the sacro-iliac synchondroses were divided on each side, with the result of allowing approximation of the anterior superior iliac spines to the extent of one inch, with corresponding diminution of the gap existing in the situation of the symphysis pubis. This gain was maintained by means of continuous extension. On January 22, 1887, an attempt was made to unite the opposite boundaries of the bladder, which failed, presumedly, in great part, in consequence of the tension due to the old cicatrix. The bladder was then covered by means of a single lateral Thiersch's flap at a later date, the exposed surface having been reduced in area from $3\frac{1}{4}$ by $3\frac{1}{4}$ inches to $1\frac{1}{2}$ by $1\frac{1}{2}$ inches, by the closure of the symphysial gap. The special features of the case were discussed, and some of the possible objections to the method considered, the following advantages being claimed for it: 1. Saving of time. In one of Trendelenburg's cases the whole procedure, excepting the closure of a small fistula, occupied eight weeks only. 2. A perfect mucous lining to the new bladder, interrupted only by a median cicatrix, is attained. 3. Failure of the primary operation in no way prejudices subsequent measures. 4. Should primary union fail, much smaller flaps are needed than in the usual operations. 5. The superficial area is not merely lessened, but a gradual backward sinking of the bladder wall accompanies the decrease in diameter. 6. The last two points are of special importance in cases like the one related, where cicatrices interfere with the ready fashioning of flaps. 7. The closure of the symphysial gap offers a better support for the abdominal viscera.

LUMBAR COLOTOMY.—At a recent meeting of the London Medical Society (*The Lancet*) Mr. Herbert Allingham read a paper on the "Causes of Failure to find the Colon in Lumbar Colotomy and the Manner of Obviating them." After some prefatory remarks on the frequency of failure in performing this operation, Mr. Allingham proceeded to discuss the anatomical structure of the large intestine. He said that the discovery of longitudinal muscular bands was the only sure sign of importance that the large and not the small intestine had been reached; these bands were detected more easily when covered by peritoneum, and therefore to insure the discovery of them, and the consequent reaching of the large intestine, the peritoneum should generally be opened. From the experience of himself and his father, he concluded that the best incision was one with its centre between the anterior and posterior superior spines of the ilium, and midway between the last rib and the iliac crest; it should be between two and three inches in length. He then discussed the various positions which the right and left colon might occupy with regard to their peritoneal covering. These fell under three heads: 1. When the peritoneum left the posterior part of the gut uncovered; according to his statistics this only occurred in 18.3 per cent. of cases on the right side, and in 16.6 per cent. on the left; in this case, if no longitudinal bands could be seen, the peritoneum should be intentionally opened. 2. When the colon was entirely surrounded by peritoneum, and possessed rather a short mesentery. Here the longitudinal bands could be neither seen nor reached without opening the peritoneal cavity, and, according to him, this occurred in 81.6 per cent. of cases on the right side, and in 83.3 per cent. on the left. 3. When the mesentery was much longer, so that the large intestine was liable to slip to the side of the abdomen opposite to that in which the incision was made. This condition had heretofore been the *crux* of operators. In both the latter cases it was indispensable to ascertain that the gut had longitudinal bands before opening it, and in both it was necessary to introduce the finger or the hand; the methods of so doing were demonstrated by diagrams.

ORGANIC POISONS IN RESPIRED AIR.—In a paper read before the *Académie des Sciences*, by Dr. Brown-Séquard, as the joint communication of himself and M. d'Arsonval, there are detailed the results of a study of respired air. It appears that in the air respired by all air-breathing animals, in addition to the poisonous carbonic-acid gas, there are other poisons, of an organic nature, and possessing properties akin to certain organic alkaloids. Among the experiments detailed were a series of intravenous injections of distilled water through which a current of expired air had been forced. In every instance the injection was followed by an enlargement of the pupil, marked slowing and irregularity of the respiratory movements, paralytic weakness of the hinder parts, especially the legs, and a rapid lowering of temperature. The action on the heart, at first feeble, with a tendency to lowering the number of beats, was, after a day or two, very strongly marked in the opposite direction, viz., great rapidity of beat. When more concentrated injections were given the foregoing symptoms were intensified, and to them was added a choleraic diarrhœa. The liquid which produced these effects was neutral in reaction, even to the most delicate tests. A further report is promised by the authors.

THE UTILITY OF LARGE AND LONG-CONTINUED DOSES OF PILOCARPINE IN BRIGHT'S DISEASE.—Drs. D. Benezúr and S. Csatáry, assistants to Professor Wagner in the medical faculty of Buda-Pesth, give the following summary of a series of articles on the effect of pilocarpine chloride in Bright's disease: 1. The patients become accustomed to the pilocarpine, and even large doses, such as six centigrammes, do not at a later period produce such disagreeable after-effects as doses of one centigramme at the beginning of the treatment. The injections of pilocarpine should not be discontinued in consequence of symptoms which had been considered as being dangerous. 2. The effect of pilocarpine on the daily secretion of saliva, sweat, and urine, as well as on the daily oscillations of the amount of hæmoglobin in the blood, is in most cases regulated by the stage of the disease and by the quantity of liquid which had been taken. 3. The œdema disappeared the more rapidly the larger the dose of pilocarpine given, and the less the quantity of liquid which the patient has taken. 4. Pilocarpine considerably increases the density of the blood, for from four to five hours. 5. The hydræmia in Bright's disease does not depend on the amount of the œdema. 6. The quantity of hæmoglobin in the blood diminishes, that is to say, the hydræmia increases when the general condition of the patient becomes impaired during the course of the disease. 7. When used according to the above-mentioned principles, pilocarpine will be found in most cases of Bright's disease, even when hot baths and other diaphoretics prove useless, always to diminish dropsy to such an extent that the patient is more or less protected against dangerous uræmic suffocative attacks. In this way it may be possible to obtain a relative cure; that is, in secondary granular contracted kidney.—*The British Medical Journal.*

ARTERIAL AUSCULTATION.—Apart from aneurismal bruits and the conduction of murmurs generated at the aortic orifice, the practice of auscultation of the arteries is not of much service. Yet the subject has often received attention, with comparatively little profit. Perhaps the chief difficulty toward a clear distinction of the sounds audible over the larger arteries lies in the fallacies due to the pressure produced on the vessel, and other conditions of which we are ignorant (*The Lancet*). Where, for example, is to be found a satisfactory explanation of the "subclavian murmur," at one time wrongly held to be distinctive of commencing tubercular deposit in the apex of the lung? Dr. Hockhaus has made a number of observations upon auscultation of the femoral artery in health and disease, in which he somewhat extends the conclusions arrived at by Weil in his work on auscultation of arteries and veins (Leipsic, 1875). The results obtained by Dr. Hockhaus are thus stated: 1. Pressure murmur and pressure tone are usually perceived in normal as well as in pathological cases; it is only where there is marked atheroma that the pressure tone cannot be produced, owing to the loss of elasticity of the arterial wall. 2. A spontaneous tone is heard (*a*) always in aortic incompetence, because the diastolic expansion of the artery is notably increased by the action of the hypertrophied left ventricle; (*b*) nearly always in uncompensated mitral regurgitation, in anæmia, and in febrile diseases, because in these affections the initial tension in the arterial system is lowered, while the maximum tension (during diastolic expansion of the vessel) remains, so that a marked difference is caused between them. 3. The double tone noted by Traube was seldom observed in cases of aortic regurgitation; but a diastolic double tone, due to irregular contraction of the ventricle, was more common. 4. The diastolic and systolic murmur (double souffle of Durosiez) is heard in all well-marked cases of aortic regurgitation, often also in combined aortic incompetence and stenosis; for the former it is pathognomonic, although it has in isolated instances been met with in typhoid fever, anæmia, and atheroma. Both murmurs are due to narrowing of the vessel. 5. With the exception of aortic regurgitation, ausculation of the femoral artery is of no prognostic or diagnostic value in disease.

THE MICROBES OF THE ALIMENTARY CANAL.—The importance of micro-organisms is daily assuming greater proportions. The part they play in the pathological processes of inflammation, and its consequences, suppuration and necrosis, have been already clearly pointed out. A fresh contribution has just appeared from the pen of M. Vignol, recording the results of experiments that have been for some time past carried on in the Laboratoire d'Histologie du Collége de France on the micro-organisms that are to be found in the alimentary canal (*The Lancet*). In the first place, M. Vignol made a careful investigation of the various forms of micro-organisms that are to be found in the mouth in health. Before commencing it, however, he naturally asked himself the question, What is the normal or healthy state? and the reply was fraught with so many difficulties, and was so immediately dependent upon the period of life, the food, and other conditions, that he found himself at last reduced to the examination of his own mouth and its secretions, after he had spent three months in the country. For the isolation and recognition of the different forms of microbes he obtained from the mouth, M. Vignol adopted the usual methods of procedure with sterilized gelatine, gelose, and agar-agar, in both sterilized air and in hydrogen gas. The results of his experiments give the astonishing number of eighteen distinct microbes, apart from ferments and the spores of moulds, which are only accidentally or occasionally present. Among these eighteen microbes six proved to be already well known—namely, the staphylococcus pyogenes aureus and albus, the leptothrix buccalis, the bacterium termo, the bacillus subtilis, and the vibrio rugula. Of the others, though some might have been seen by Rasmussen, Miller, and others, their descriptions were not sufficiently exact to enable them to be identified. Of the remaining twelve, only one, named the spirochete denticula, could not be artificially cultivated, and M. Vignol has commenced a fresh series of experiments with the hope of better success in this direction. The rest he distinguishes by italic letters, as bacillus *a*, bacillus *b*, and so on, giving their mode of growth and dimensions. M. Vignol has further endeavored to follow the action of the microbes on the food by inoculating milk and other fluids with pure cultures. By proceeding in this way he has found that the staphylococcus aureus and albus and the leptothrix buccalis (the very poisonous action of the former of which through the skin is now well known and was described by Professor Watson Cheyne in the lectures he has just given at the Royal College of Surgeons), while incapable of attacking or effecting the solution of albumen, fibrin, or gluten, and ineffective in converting potato-starch into sugar, yet when milk was inoculated with them coagulation took place, apparently from the development of various acids, among which lactic acid was the most conspicuous. On the contrary, the bacillus subtilis, the bacterium termo, and the vibrio rugula, with the several bacilli M. Vignol has discovered, all, or almost all, render albumen transparent and dissolve albumen and fibrin, though they appear to have little action on gluten and starch. The microbes found in the mouth seem to be capable of resisting the action of the gastric, biliary, and pancreatic juices, for several hours at least. The general conclusions at which M. Vignol arrives are that many microbes enter the economy with the food and are carried on by the saliva into the stomach. Here their activity may perhaps be temporarily lowered or arrested, while some may perhaps be destroyed, but the majority enter the small intestine and contribute by their action to render ingested substances soluble—that is to say, assimilable by the lacteals; their number, which rises to more than twenty millions per decigramme in the fæces, shows the intestinal media are favorable to their growth, and renders it probable that the part they play in the process of digestion and the transformation of food is not inconsiderable—conclusions that are quite in accordance with the views of Pasteur.

VIEWING THE CIRCULATION OF THE BLOOD IN THE CORNEA.—"At Professor Hirschberg's clinic, in Berlin," writes a correspondent of the *Kansas Medical Index*, "my attention was called to the fact that the circulation of blood in the blood-vessels of the cornea affected with pannus can be seen. If one could not see this in America it might almost be worth a trip across the ocean. By the aid of a strong lens one sees the circulation here almost as well as in the web of a frog's foot or in a fish's tail."

THE MEDICAL RECORD:

New York, July 21, 1888.

THE CAUSE OF DEATH IN HYPERPYREXIA.

IT is, of course, well known that the temperature of the body varies within comparatively narrow limits, and that when these limits are passed, on one side or the other, death inevitably follows. Claude Bernard placed the upper limit at about 115° F., but a much lower temperature than this is usually regarded as fatal, and it is seldom that an individual recovers from a temperature of 108°, maintained for any length of time. But though we know the fact that hyperpyrexia kills, we have never learned in what way it kills.

Bernard suggested that death, in these cases, was due to a coagulation of the fluid portions of the muscles, especially of those of the heart; but this explanation has never been accepted, since death often occurs before this rigor caloris takes place, and furthermore, the heart often continues to beat after respiration has ceased. An excessive bodily temperature undoubtedly weakens the heart, and this possibly contributes to the lethal issue, but in the light of clinical facts it cannot be regarded as the sole, or even as the most potent, cause of death. Another theory, even more unsatisfactory, is that the high temperature causes an expansion of the gases contained in the blood. Chaussat thought that death was due to an inspissation of the blood produced by an excessive evaporation through the skin and lungs, but if this were all, saline transfusions would suffice to prolong life indefinitely.

Dr. H. Vincent, of Paris, in a recent thesis, reviews the various theories hitherto offered, and shows that they are all equally untenable, and then proposes one of his own, which seems to him to be more reasonable and more in accord with the known facts. He has studied carefully the various symptoms, on the part of the circulation, the secretions, the respiration, etc., presented by those dying of hyperpyrexia, and also the lesions found post mortem, and concludes that death is due to an auto-intoxication caused by an accumulation in the blood of various waste products. The excessive temperature causes increased waste of the tissues, and also interferes with the speedy elimination of the poisonous products resulting therefrom. These poisons accumulate in the blood and act upon the central nervous system, more especially upon the respiratory centres. Death results, therefore, from an arrest of the respiratory functions.

It cannot be said that Dr. Vincent has solved the problem presented, but he has at least offered a more plausible explanation of the cause of death in hyperpyrexia than his predecessors in this line of reasoning. And his work will be not without value if it serves to awaken an interest in this subject, which seems to have been neglected since the death of Claude Bernard. The question is an important one, for, even with the new means of lowering the temperature of the human body which modern synthetic chemistry has given us, it is not always possible to prevent hyperpyrexia. If we but knew how death was brought about in these cases, we might be able to devise means of averting it for a time, until nature could reassert herself and bring the patient back within the lines of safety.

THE GOAT *versus* THE COW.

THE *British Medical Journal* advocates a wider use of goat's milk and a more systematic attempt to cultivate the lacteal resources of *Capra ægagrus*. Our contemporary's editorial ought to send joy to the hearts of the citizens of our now decadent Shantytown. Its arguments are that the cow's milk in cities is never free from the suspicion of infection or adulteration. The goat, on the other hand, does not have or very rarely has tuberculosis, is easily kept clean, and is a vigorous and healthy animal, thriving under almost any conditions; and, lastly, the goat's milk itself, as is well known, is more easily digested by infants than cow's milk.

The analysis of Gorup Besanez stands thus: The quantity of water contained in 100 parts of human, cow's, and goat's milk, respectively, is 88.9, 85.7, 86.35; of solids generally, 11.1, 14.3, 13.6; of casein, 3.9, 4.8, 3.36; of albumen, a trace, 0.5, 1.29; of fat, 2.66, 4.3, 4.3; of milk-sugar, 4.36, 4, 4; of salts, 0.13, 0.54, 0.62. Professor Fleischmann compares cow's with goat's milk as follows: There are of water 83.6 to 90 and 85 parts in cow's and goat's milk respectively; of fat, 2.8 to 4.5 and 4.8; of casein, 3.0 to 5.0 and 3.8; of milk-sugar, 3.0 to 5.5 and 4; of albumen, 0.2 to 0.6 and 1.2; of ashy salts, 0.4 to 0.8 and 0.7. These analyses agree in the main, and thus goat's milk, holding more albumen, is cheaper, bulk for bulk, than that of the cow. Taking everything into consideration, goat's milk might be provided at less cost than cow's milk. The chief advantage of the former lies in its ready assimilation by the digestive organs of the infant, owing to its relatively small proportion of casein, less than that of human, and much less than that of cow's milk.

THE RELATION OF THE EXCRETION OF URIC ACID TO DISEASE.

DR. A. HAIG, as the result of a series of observations and experiments upon the relation of the excretion of uric acid to disease (*Journal of Physiology*, vol. viii., Nos. 3 and 4), thinks that he has shown: 1. That the excretion of uric acid can be controlled by drugs and foods in a way and to an extent not previously known; that, whatever the amount excreted to-day, it may, within certain limits, be made either greater or less to-morrow.

2. That, when uric-acid excretion is diminished relatively to the urea, the diminution is due to retention in the liver and spleen, and possibly in some other organs and tissues, of part of the uric acid which was formed; and, conversely, when uric-acid excretion is increased rel-

atively to the urea, such increase is due to a washing out of a store previously accumulated in the above organs and tissues.

3. That the formation of uric acid bears an almost constant relation to that of urea, though its excretion can be varied by food and drugs to a considerable extent.

4. That uric acid is probably never in excess in the blood, except when alkalies or other solvents wash it out in considerable quantities from the stores which have gradually accumulated in the above-mentioned organs.

5. That excess of uric acid in the blood, brought about in this manner, is a sufficient cause of many of the symptoms of the diseases I have mentioned, and probably of others also.

6. That drugs and foods which diminish the solubility of uric acid diminish its excretion and lead to retention and accumulation; and, conversely, foods and drugs which increase its solubility facilitate its excretion and prevent retention.

7. That drugs which diminish the solubility and excretion of uric acid are harmful in the diseases connected with it, while drugs which increase its solubility and excretion are useful in these same diseases.

Dr. Haig found that his attacks of migraine could be produced at will by increasing the acidity of the urine and thereby favoring the retention of uric acid. He prefers to call migraine a uric-acid headache. Attacks of gout and many attacks of epilepsy he traces to a similar cause.

Referring to the effect of diet on uric-acid excretion, the table of Lehmann is given:

	Urea.	Uric acid.
Mixed diet..........................	32.4	1.1
Animal diet..........................	53.1	1.4
Vegetable diet..........................	22.4	1.0
Non-nitrogeneous diet................	15.4	0.7

This shows that, in fact, an animal diet increases the absolute amount of uric acid, though diet evidently affects much more decidedly the amount of urea. But Dr. Haig claims that the real significance lies in the fact that the uric acid is relatively diminished by an animal diet. Thus:

	Urea.	Uric acid.	Relation.
Mixed diet................	32.4	1.1	1-29
Animal diet...............	53.1	1.4	1-38
Vegetable diet............	22.4	1.0	1-22
Non-nitrogeneous diet.....	15.4	0.7	1-22

His view is that the amount of uric acid manufactured daily is in a fairly constant ratio to urea, viz., 1 to 33, Thus, he says: "It will be seen that on mixed diet there was slightly excessive excretion of uric acid; on animal diet considerably diminished excretion (retention), and on vegetable diet excessive excretion, some of the previous retention being washed out. And a continuance of the animal diet would obviously soon produce a store of uric acid sufficient to account for anything from a 'bilious' to a gouty attack. The results in these tables are similar to those I have obtained with various diets, and the relation of uric acid to urea are just those I meet with in my every-day work.

"I have been led to infer from all these facts, that while the formation of uric acid alters but little from its relation to urea of 1 to 33 (subject, I have no doubt, to some small variations) its excretion is subject to frequent and great fluctuations, which account for its action in the production of disease."

The effects of drugs are as follows:

Iodide of potassium has, in five-grain doses, but little action on the excretion of uric acid; in larger doses it acts apparently merely as an alkali. Iodine taken as the tincture has little or no direct effect.

Phosphate of sodium is a well-known solvent of uric acid, and it does, just as one would expect, greatly increase its excretion; it is probably the chief solvent of uric acid which is naturally present in the body.

Salicylates have the very important action of rendering the excretion of uric acid independent of acidity, that is, a rise in acidity does not cause retention while salicylates are present in the blood; and this fact may explain much of the value of these salts in diseases connected with uric acid.

Lead and iron.—The urates of these metals are very insoluble, and they cause, as one would expect, retention of uric acid, which, as we shall see, may explain their action in several diseases.

Colchicum.—This indirectly lowers acidity and facilitates the excretion of uric acid. It may also have a direct action on the nerves in relieving the pains of gouty arthritis.

PROFESSIONAL COURTESY.

ONE hears so much about the jealousy of physicians, of their mutual backbiting, quarrelling, and generally splenetic state toward each other, that it is really somewhat refreshing to learn that we are not in reality a disunited body. Our esteemed contemporary *The Journalist*, for example, has recently celebrated our united state in the following somewhat ferocious terms:

"There is not in this world to-day a more powerful, more monstrous, more unjust, and iniquitous organization in existence than that mysterious bond which fetters the medical profession as with links of steel, which is known as 'Professional Courtesy.' Professional courtesy is an excuse for neglect, for procrastination, for carelessness which is in too many cases tantamount to murder. It is no rash statement to assert that there are hundreds of cases known to physicians who are in other respects reputable men, where patients have died through the criminal neglect and stupidity of the attendant physician. Yet you could not worm an admission of that sort out of them in a court of law—they are bound by 'professional courtesy' to allow their ignorant, incapable fellow practitioner to go on murdering without a word of remonstrance."

Thus it seems that physicians do stand by each other after all. This is not very surprising, when one considers the difficulties and limitations of our art. When an architect miscalculates in building a bridge, his incompetency can be demonstrated mathematically, but when a chronic invalid with some obscure malady receives a series of prescriptions under which he or she gets no better, the incompetency of the physician is hard to prove. The malady may itself be impossible of recognition and of cure. Doctors know this. It compels them, if they have any sense of justice, to charity toward their fellows. We follow a difficult and laborious calling. There are black sheep everywhere, and sometimes, perhaps, "professional courtesy" has been made to shield them. But we do not think that harm often comes from its exercise, and, indeed, medicine could not be practised without it.

In one respect our contemporary signally errs. He says: "If you employ a physician to patch up the health of a member of your family, and you find after a reasonable trial that instead of building up he is tearing down, you can dismiss him and get another? Not much. Go and ask another physician to take the case and he will tell you blandly that 'professional courtesy' will not allow him to take another doctor's case, without the first doctor giving his permission, and if number one chooses to be ugly you have a boycott beside which the boycotts of the labor organizations are mere child's play."

A patient who is dissatisfied with a physician has only to say, in as amiable terms as possible, that he has no further need of the latter's services. He can then engage any other physician that he wishes.

News of the Week.

The Southern Surgical and Gynecological Association holds its annual session at Birmingham, Ala., on September 11, 12, and 13, 1888. Papers have been promised by a large number of the leading surgeons and gynecologists of the South. Dr. W. D. Haggard, of Nashville, Tenn., is President, and Dr. W. E. B. Davis, of Birmingham, Ala., Secretary.

The Texas Medical College.—We are glad to learn, with reference to this newly established college, that though not endowed, it has funds guaranteed which enable it to require three years' study and three full courses of lectures of its graduates. It gives a twenty-two weeks course. No new medical college should be opened, however, which does not require also a preliminary examination. We have three times as many colleges and twice as many doctors in this country as are really needed. There is only room for first-class colleges and first-class doctors, now. We trust the Texas Medical College will become the one and make the other.

Professor Virchow has been awarded the gold Boerhaave medal for Anthropology by the Scientific Society of Haarlem.

Common Slag is said to be a remarkably efficient material for deodorizing and absorbing fecal matter and urine.

Of the Much-advertised Operations for transplantation of the cornea, *The Lancet* says: "This operation has been frequently performed, but hitherto without permanent success. Various cases have been recorded by Messrs. Power, Sellerbeck, and others, in which the new cornea taken from cat or dog, the eye of which is preferable to that of the rabbit, has formed adhesions and retained its transparency for some days or weeks, but sooner or later the new cornea becomes hazy, contracts to a button, and is finally absorbed or sloughs out, and the patient remains unimproved."

The Sticking-plaster treatment of erysipelas is highly recommended by Professor Wölfler, of Grätz. Strips of isinglass plaster about the breadth of the thumb are applied over the affected surface.

A Cancer Quack, it is reported, has been told to be in readiness to attend Mr. Jay Gould.

Dr. T. M. Cheesman, of this city, died last week.

Dr. H. L. Burritt, of Bridgeport, Conn., died on July 11th. He graduated from Yale in 1844, and was a surgeon during the war of the Rebellion.

The Attempts to find a Microbe which will kill the Australian rabbits are being vigorously prosecuted. Pasteur's pupils, Drs. Hinds, Loir and Garmont, have arrived at Sidney and begun cultivating their chicken-cholera germs. They have also discovered the existence of charbon in Australia, and possibly the charbon bacilli may be used.

Science and Sentiment.—That the unswerving pursuit of science, *i.e.*, the study of natural phenomena, the weighing of evidence, and groping for facts and laws, dwarfs the æsthetic element in a person's character, there can be no doubt. No better illustration of this can be found than that of Mr. Darwin. He says in his autobiography: "Up to the age of thirty, or beyond it, poetry of many kinds, such as the works of Milton, Byron, Wordsworth, Coleridge, and Shelley, gave me great delight, and even as a schoolboy I took intense delight in Shakespeare. I have also said that formerly pictures gave me considerable, and music very great, delight. But now, for many years, I cannot endure to read a line of poetry. I have also almost lost my taste for pictures or music." Fortunately, the doctor has to deal not only with science but with human nature in every possible phase. His practical work tends to cultivate the better and kinder side of his character, and he is rarely in danger of the æsthetic atrophy which befell Darwin.

Billroth and Mackenzie.—Professor Billroth has sent the following letter to a German paper, in response to a request for his opinion upon the case of Emperor Frederick: "With reference to your request for my opinion on Mackenzie, I can only reply that I have always warned people against passing a judgment on a man who, as a physician, occupies so difficult a position. I have never doubted the correctness of the diagnosis of my Berlin colleagues, but I have also never been able to understand what political reasons had made it necessary to communicate this diagnosis to the whole world. It cannot be admitted that Mackenzie with his vast experience has ever doubted the correctness of this diagnosis. If he behaved in such a way as to imply that he had some doubt about the correctness of this diagnosis, this could only be owing to pressure from above or from motives of humanity. I know such situations from my own experience. One is not inclined to disapprove the statement of one's *confrères*, but at the same time one is not inclined to tell the patient that his malady is incurable, for the known want of infallibility in medical diagnosis is almost the sole ray of hope to the unfortunate incurables. Falsehood in such cases becomes a moral act. The entire behavior of Mackenzie must, no doubt, be judged from this point of view. He did as a man and physician what was still possible to be done when the unfortunate word 'cancer' had already been pronounced. In much the same terms as these I have on different occasions expressed myself as to Mackenzie's conduct. I ask you to consider this as a private communication, at least until the sad catastrophe has occurred in Berlin.—Yours most respectfully, Dr. Th. Billroth."

THE LATE DR. MILNER FOTHERGILL.—The turn of a physician's thoughts, writings and work is often affected by his own personal ailments. This was the case with the late Dr. Fothergill, who, during the last years of his life, suffered from diabetes and gout, and who wrote constantly on nutritional disorders. The *British Medical Journal* says of him: "Dr. Fothergill had for many years suffered from diabetes, of which the symptoms recently became much aggravated, and have now proved fatal, gangrene of the foot having set in followed by fatal coma. Dr. Fothergill's career was in many respects a remarkable one. Without friends, without official position, and never having been elected a Fellow of his College, Dr. Fothergill nevertheless attained a position of considerable influence in medical literature, and was justly esteemed as an authority of no little weight in a great variety of diseases, especially those connected with nutrition. His writings, which were numerous and voluminous, were vigorous in style, interesting in matter, and original in thought. Though his strongly pronounced personal characteristics may have interfered in many respects with his success in life, they made him a very marked and interesting personality. He was by birth and characteristics a Westmoreland dalesman, witty, humorous, though somewhat unpolished in speech and rough in manner. A certain sense of personal grievance, under which he labored during a large part of his life, made him often unduly aggressive, and thus interfered in some degree with his social and professional advancement; but his power, vigor, and genial humor brought him deservedly a very wide circle of friends who esteemed his independence of character and his intellectual power, and who will greatly regret his premature death." In some of Dr. Fothergill's later writings he had made a somewhat fanciful classification of persons who in this day suffer from gout and other nutritional diseases into the Norse and the Arab type; he himself was a pronounced example of the former type, which is unfortunately little adapted to the cramped physical surroundings of city life.

ARTIFICIAL CARLSBAD SALTS.—The fulsome advertisements of these salts in various ways may have tended to obscure the fact that very cheap and effective artificial preparations can be made. One of these is that suggested by Ziemssen: Sulphate of sodium, 40 parts; carbonate of sodium, 6 parts; chloride of sodium, 1 part. This should be dissolved in hot water, then the latter evaporated, the remaining salt powdered, and a proper dose of this (one-half teaspoonful) taken in hot or carbonated water.

THE PARADISE OF QUACKS.—It is stated in *La Voz de Hipocrates* that in the City of Mexico, containing some three hundred and fifty thousand inhabitants, the quack practitioners, male and female, are more than twenty-three times as numerous as qualified men, of whom about four hundred only have been recognized by the faculty of medicine. The irregular practitioners are thus classed: 1,800 so-called homœopathic doctors, 200 so-called dosimetric doctors, 3,000 male herbalists, 1,000 female herbalists, 100 female dosimetricians, 8,000 compounders, 300 male and female sorcerers.—*Lancet.*

PHYSIOLOGICAL MANIKINS IN THE PRACTICE OF MEDICINE.—The *Medical Press and Circular* makes the following extraordinary statement: "A 'Physiological Manikin' has just been introduced to the profession of this country which bids fair to revolutionize the teaching in medical schools; and as 'explanatory therapeutics' is becoming the order of the day, we may expect to hear that it has found its way into the consulting-room of many of our leading physicians. Already we learn that the example set by the profession in France, of explaining by models to patients the seat of their ailments and the *rationale* of proposed treatment, which has been found to impart the confidence so necessary to successful treatment, has lighted on congenial soil in America, where upward of five thousand copies of this said manikin are said to be already in the hands of the profession. Whether the same results will follow in this country remains to be seen. Certainly the manikin is a wonderful work of art, and we can readily believe that in the teaching of physiology in schools it will at once supersede the flat surfaces of pictures and diagrams hitherto in use." We very much doubt the statement that five thousand manikins, or even five of the kind above described, have been introduced into this country. A physiological manikin, to be worth anything, must represent so much work as to make it very expensive.

WE ARE GREATLY pleased to find so many of our readers familiar with the Scriptures. We have received from several esteemed correspondents statements of the book, chapter, and verse in Scripture which says that he who does not provide for his own is worse than an infidel—1 Timothy, chap. v., verse 8. That the verse furnishes no justification to the sordid advice of "keeping the eye on the fee, first, last, and all the time." is apparent.

DR. STEWART, OF LONDON, is to marry a sister of the Duke of Norfolk. This item of news is considered of sufficient importance to be cabled across the Atlantic. We venture to congratulate the Norfolk family on the prospective alliance, and meanwhile we await with impatience the column leader which the *Lancet* will write upon the important social event.

A MILLION DOLLARS FOR A SPANISH MEDICAL COLLEGE.—The first stone of a new medical faculty and clinical hospital for Barcelona was laid on May 28th. There was a great ceremony, the Minister of Education and all the municipal and university authorities being present. The government has assigned a million dollars for the buildings, and the local authorities have given the site.

A SIGNIFICANT ACT.—"Perhaps the most significant action on the part of the American Medical Association was the abolition, and upon motion of Dr. N. S. Davis, too, of the rule which compels all members to sign the code of ethics. Just what this vote portends is at present not apparent, but there must be some kind of a fish beneath the troubled waters."—*Kansas City Medical Index.*

ANTISEPSIS IN TYPHOID.—Intestinal antisepsis in typhoid-fever cases seems to be in a good way of becoming of the highest importance. In the treatment of such patients, Professor Bouchard first introduced naphthol, and Dr. Legroux is at present applying it in his service at the Children's Hospital with great success. As soon as a child is brought in suffering with symptoms of typhoid, the intestines are at once cleared out with calomel. given in doses of 0.30 to 0.60 centigrammes, depending on the child's age. The next day the intestinal antiseptic treatment is commenced as follows:

℞. Naphthol beta,
Bismuth salicylate, āā 2.50 grammes.

M. Divide into ten powders, and give one every hour in a wafer, or mixed with a little milk or brandy.

If the diarrhœa is not important, the bismuth may be left out and only the naphthol given, and if, on the contrary, there is constipation, then the following if used:

℞ Naphthol beta	2.50 grammes.
Magnesia salicylate	2.50 to 5 grammes.

M. Divide in ten powders, and give one every hour until the bowels are free, and then continue with the naphthol only, as before.

It will be found that there will be a diminution or entire suppression of intestinal meteorism, and that the stools are disinfected, no longer giving the fetid smell of typhoid, and also the mouth and tongue will clear up, the general state will improve, and the disease will run a short course.—Paris cor. *Phil. Med. Times.*

PRIORITY IN NEPHRORRHAPHY.—Texas is a great State, with a virile and progressive medical population, and a *Daniels' Texas Medical Journal* to see that the giant young republic gets its due. The said journal's latest claim for the Lone Star is that the late Dr. Dowell performed the first nephrorrhaphy for floating kidney. What Dr. Dowell really did, was to pass a seton through a movable tumor of the kidney and out of the abdominal wall. The patient subsequently went crazy. Dr. Smyth removed the kidney, which was found to have a scar in it caused by the seton. Dr. Hahn, in 1881, was the first to conceive and carry out the operation of nephrorrhaphy.

DOM PEDRO'S TREATMENT.—Some attention has been paid to the recent treatment by which the old Emperor of Brazil was brought out of his illness at Milan, and is now fast recovering at Aix-les-Bains. It was hypodermic injections of caffeine that saved him, and in this connection it should be remembered that caffeine is an uncertain drug, that has to be given in sufficient quantity in heart failure, and yet if too much is given it may prove fatal. It is also very insoluble in most or all of its salts, such as the citrate, etc., and it may be well in this connection to give Dr. Huchard's formula:

℞. Caffeine	2 grammes.
Benzoate of soda	3 "
Distilled water	6 "

M. (Make the solution while it is warm.)

From four to six injections per day, the usual syringeful used each time of this solution, is the proper dose. It will be found to act as a general tonic, a cardiac tonic, and above all as a *diuretic*, being perhaps the best of all for this last purpose. The salts of caffeine are not used here now at all, but the drug itself combined with benzoate of soda to make it soluble.—Paris cor. *Phila. Med. Times.*

SUGAR-STICKS FOR INEBRIETY.—M. Jean Desbouvrie, of Roubaix, has recently proposed to the Paris Academy of Medicine a novel remedy. From experiments made upon himself he is satisfied all the noxious effects of alcohol can be avoided if the drinker will take the precaution of fortifying his stomach beforehand with an appropriate food containing an adequate proportion of albuminous and fatty substances. M. Desbouvrie, thererefore, has invented a chocolate containing a certain proportion of albumen, specimens of which were sent to the Academy, together with the memoir. Those who feel like going on a spree will only have to munch a stick of the chocolate, and they may have a good time of it without fear of the to-morrow's headache.

URINE AS A VACCINE.—M. Bouchard claimed in 1884 that the urine of cholera patients contained the specific virus of the disease. He now, in a communication to the Académie des Sciences, announces that the urine in the "maladie pyocyanique," filtered and injected into animals, produces some of the symptoms of the original disease, and renders the animals refractory to subsequent inoculations of pure virus.

PENGAWAR DJAMBI, A NEW HÆMOSTATIC.—The *Therapeutic Gazette*, April, 1888, says editorially of this drug: "We have long used it in the physiological laboratory of the University of Pennsylvania as a hæmostatic. It was originally brought to us by Dr. Lautenbach, who had learned the value of it while working in the laboratory of Professor Schiff, at Geneva. To the physiological surgeon it is extremely valuable on account of its power of rapidly coagulating blood and forming a plug, which for the time being will stop hemorrhage even from large venous vessels. Thus, in opening up the spinal cord there is usually an excessive outpouring of blood from the torn sinuses, an outpouring which may be at once arrested by stuffing pengawar djambi into the wound. It is free from irritant properties, and we see no reason why it could not be made the bearer of antiseptic substances. Under its influences we believe that any cut surface would rapidly dry, and we trust some of our surgical readers will make a practical test and report the results in our columns."

Obituary.

DR. A. Y. P. GARNETT.

DR. A. Y. P. GARNETT, of Washington, D. C., ex-President of the American Medical Association and ex-Surgeon-General of the Confederate Army, died at Rehoboth Beach, Del., on July 11th, of heart failure. He had been severely ill for several days and was believed to be slowly convalescing. He left Washington for the seashore for the purpose of recruiting his failing health. He was born in Virginia in 1820, was graduated in medicine at the University of Pennsylvania in 1841, entered the United States Navy as Assistant-Surgeon the same year, was promoted Surgeon in 1848, and resigned in 1850 in order to accept the Professorship of Clinical Medicine in the National Medical College of this city. He married the eldest daughter of Henry A. Wise. At the breaking out of the war he left Washington and became Surgeon-General of the Confederate Army. He was the family physician of Jefferson Davis and of all his Cabinet officers, and accompanied Mr. Davis after the evacuation of Richmond. At the close of the war he returned to Washington, and was again elected a Professor in the Medical College. He was elected President of the American Medical Association in June, 1887.

Society Reports.

NEW YORK PATHOLOGICAL SOCIETY.

Statea Meeting, April 11, 1888.

W. P. Northrup, M.D., President, in the Chair.

The President presented, on behalf of candidates, a specimen of *Acute Suppurative Arthritis following Scarlatina*, and one of *Supernumerary Finger*.

Dr. Hodenpyle presented specimens showing

CARCINOMA OF THE PERITONEUM

and carcinomatous nodules in the liver, spleen, and body of the uterus.

Mrs. O——, aged forty, widow two years. Family history negative. She was married at the age of seventeen. up to which time she had always been healthy. She had had two children, the last thirteen years ago. No miscarriages. Menstruation was regular up to the age of thirty-four years. when it ceased. Since then she suffered for a considerable time, in place of her regular monthly periods, with difficult, painful, and frequent micturition, severe pain in the back, and slight swelling of the abdomen. In July, 1887, she was taken with pretty severe pains in the hypogastrium, coming on in attacks lasting about twenty minutes. In September of the same year she noticed a "lump" in the right iliac fossa which gradually grew in size, and was accompanied by swelling of the abdomen. She was then admitted into the New York Hospital, where she says she was examined under ether, that when she came out from the ether her abdomen was tightly bandaged, and when this was removed there was seen a small, nodular, soft, painful growth protruding from the umbilicus. She was a good deal emaciated, and a microscopical examination of the growth at the umbilicus showed it to be an epithelioma. Abdomen moderately distended. Liver normal in size. No splenic dulness. There was a semi-fluctuating mass in the right iliac fossa, three inches in diameter. There was also a large flat mass in the centre of the abdomen, to which the growth at the umbilicus seemed to be connected. The inguinal glands were enlarged. Upon examination per vaginam, the body of the uterus and the ovaries were found to be converted into a large, hard, dense mass. The patient died exhausted April 8, 1888.

Autopsy.—Rigor mortis not well developed. Emaciation extreme. Moderate anæmia of left leg. The right pleural cavity contained a small amount of clear fluid. The right lung was large and œdematous, and contained three grayish nodules about two cubic centimetres in size. The left lung was small, being compressed toward the vertebral column by an accumulation of clear serum, inclosed by a thick, rather soft, capsule. The fluid within was contained in a number of thin-walled sacs. Bronchial glands enlarged and very soft. The adjacent pericardium was greatly thickened. Heart was very small, otherwise did not appear to be abnormal. The abdomen contained a small amount of clear fluid. The growth at the umbilicus was continuous with a large irregular mass beneath the peritoneum, to which were attached the greater omentum and portions of the intestine. The diaphragm covering the liver was greatly thickened, and the liver immediately beneath was converted into a zone of yellowish-white tissue, about one centimetre in thickness, and considerably softer than the surrounding liver tissue. Scattered through the viscus were several large whitish masses, and the rest of the organ was moderately fatty. The spleen was soft, and contained a large tumor-mass. Pancreas, suprarenals, and kidneys showed no lesions. On the external surface of the gall-bladder, mesentery, intestines, and parietal layer of the peritoneum were a very great number of larger and smaller spherical or irregular masses. In the pelvic cavity was a large mass, partly cystic, on both sides of the uterus, the body of which was greatly enlarged, the cervix and endometrium being fairly normal. The bladder was normal. The ovaries could not be made out from the tumor-mass. The inguinal glands were greatly enlarged and thickened.

Dr. Lewis Hall Sayre presented a specimen of

ROUND CELL SARCOMA

of the arm, removed from a child the day before. The child had always been in perfect health until six years ago, when the mother noticed a small painless swelling on the anterior aspect of the forearm. Various diagnoses were made, and the treatment varied accordingly. Finally, an elastic armlet was applied and worn for four years, but was then discarded because of the discomfort which it caused. For the past two years there had been no treatment. The arm gradually increased in size, more rapidly during the past eight weeks, and measured, when Dr. Sayre saw the case, nine and one-half inches in its greatest circumference. It was distended cylindrically, and was moderately hard to the touch. There were no nodules to be detected, and there had never been any pain from the commencement.

An incision was first made, but it was seen to be impossible to remove the tumor, and the arm was therefore amputated. The new growth, which was attached to the periosteum of both radius and ulna, seemed to be a round-cell sarcoma. Dr. Sayre requested that the specimen be referred to the Microscopical Committee.

Dr. James E. Newcomb presented the spleen and liver removed from a patient dead of

SPLENIC LEUCOCYTHÆMIA,

with the following history: "Mrs. M——, aged forty-three, born in New York City, of Scotch parentage. One brother died of visceral cancer; family history otherwise negative. The patient was always in good health till the commencement of her fatal illness. Had been married twenty years, and had had three children, all of whom are living and healthy.

"In May, 1885, she had an acute malarial attack, and was in bed six or seven weeks. The disease was intermittent; at first quotidian, but later tertian. There was marked enlargement of the spleen. On getting up in July, the patient noticed this splenic tumor in the left side. At times it was painful, and she had great distress in the epigastric and right hypochondriac regions. There was no stomach disturbance and no other glands were enlarged. She came under my care in July, 1886. She was markedly emaciated, though free from any definite cachectic appearance. She had had considerable epistaxis in the previous few weeks. Menstruation had ceased at the time of the first malarial onset in 1885, and was thereafter present only irregularly. At no time was there hemorrhage from any mucous membrane other than the nasal. No urinary symptoms.

"At this time the abdomen was distended with a mass, hard at some points and fluctuating at others, and resembling on palpation an ovarian fibro-cyst. No distinct areas of splenic or hepatic dulness could be obtained. She continued to emaciate. The fluid in the abdomen was mostly absorbed. About November, 1887, an examination of the blood was made by Dr. W. B. James, who reported that it presented the appearances characteristic of leucocythæmia. At this time it was possible to map out the spleen with great distinctness; it commenced posteriorly at the usual line, and projected forward somewhat across the median abdominal line. and was considerably more than a hand's-breadth in width. The liver flatness ran down to the level of the umbilicus. There was no evidence of fluid in the abdomen.

"These, then, were the four features of the case: The splenic and hepatic enlargements, the blood changes, the emaciation, and the usual symptoms of anæmia. On February 11, 1888, the patient had a fresh epistaxis, continuing at intervals till her death. She complained greatly of præcordial pain. Was seen on the 13th, and an attempt made to plug the nares with styptic cotton. Only temporary relief was afforded. At noon, on February 14th, she suddenly died.

"As soon as a definite diagnosis was made, she was placed upon Fowler's solution in addition to her previous tonics. None of the remedies employed seemed to be of the slightest service in retarding the progress of the disease.

"*Autopsy*, five hours after death, Dr. James assisting.—Permission was given only to open the abdomen and remove the 'tumors.' The liver measurements were as follows: Transverse, 31 ctm. ($12\frac{1}{2}$ inches); antero-posterior, 16 ctm. ($6\frac{1}{2}$ inches). In thickness (back part, right lobe), $7\frac{1}{2}$ ctm. (3 inches). Weight, 2,624 gms. (5 lbs. 2 oz.). The measurements of the spleen were: Length, 26 ctm. ($10\frac{1}{2}$ inches); breadth, $13\frac{1}{2}$ ctm. ($5\frac{1}{2}$ inches); thickness, 6 ctm. ($2\frac{1}{2}$ inches); weight, 1,888 gms. (3 lbs. 11 oz.). The liver seemed rather soft in consistency, and the spleen was very hard. There was no enlargement of the retro-peritoneal or mesenteric glands. No evidences of peritonitis; no fluid; kidneys apparently normal."

Dr. Van Gieson showed some specimens illustrating

ACUTE LOCALIZED MENINGITIS, PYLORIC CARCINOMA, AND HYDRO-NEPHROSIS.

The specimens were taken from a strong man, aged thirty-five. Sixteen months before death the man began to have symptoms of gastric and hepatic disturbances, apparently due to the protracted ingestion of alcohol. There was morning vomiting, general emaciation, jaundice, and inability to take food well at times; but severe gastric pain was absent, and carcinoma of the stomach was not decided upon until after a physical examination, three months before death. Five days before death symptoms of meningitis occurred, with violent mania and continuous muscular tremor confined to the legs.

At the autopsy the surface of the pia was dry; on either side of the longitudinal incision there were two nearly symmetrically situated, raised yellow pellicles ($3\frac{1}{2}$ by 2 ctm. in diameter), involving the para-central lobules. Nearly surrounding the pylorus, involving diffusely all of the coats of the stomach, was a dense, whitish mass, about 4 ctm. in diameter and 1 ctm. thick. The left hepatic lobe contained several small, hard, white nodules. The left kidney was large and white. The pelvis of the right kidney was dilated, containing 240 c.c. of acid, turbid albuminous fluid, in which were many pus-cells and a few large granular, polymorphous, nucleated cells.

Dr. H. J. Boldt presented specimens showing a

SUPPURATING OVARIAN CYST IN A CHILD,

complicated by acute meningitis. The patient was aged four years. Eight months ago the parents noticed a tumor in the lower part of the abdomen, which gradually increased in size. There was no pain up to within three weeks, when the tumor became very tender on pressure, and the child seemed to suffer pain in the abdomen. One week ago the child suddenly grew worse, became feverish and restless. When first seen by Dr. Boldt it had a temperature of 103.4° F., the restlessness had given way to apathy, and the general picture was that of meningitis. The introduction of an exploring needle into the tumor, which extended above the umbilicus, showed the contents to be pus. It now became a question whether the cerebral symptoms were due to meningitis, or whether they were to be attributed to the presence of the suppurating tumor. In view of the possibility that the latter was the case, an operation was done without delay. The tumor was found to be a simple ovarian cyst, springing from the left side, and containing from one and a half to two quarts of pus. The sac was adherent to such an extent that removal was out of the question, so the walls were stitched to the abdominal wound, the cavity was washed out, and drainage was provided for. The patient did not improve after the operation, making it clear that the meningitis was the main complication, and this was borne out by the condition found at the autopsy. Death occurred two days after the operation. The interesting features of the case were the age of the patient with a suppurating cyst of the ovary, and the complicating meningitis.

Dr. Myers presented some specimens removed from the body of a child nine years of age, who had died from

STRANGULATED INGUINAL HERNIA.

The points in the history of the case, for which he was indebted to Dr. F. T. Hopkins, were as follows: The child had a congenital hernia. One evening the nurse noticed a dark-colored swelling in the groin, but did not think it had any significance and said nothing about it. The child soon after began to show evidences of intestinal obstruction; there were no movements from the bowels, the temperature was high, and there were a rapid pulse and shallow respiration. The child was seen at this time, and the question now was whether there was gangrene or not. It was thought that there was probably no gangrene, as the symptoms of strangulation had existed for so short a time, and it was therefore decided not to operate. Taxis was tried and the tumor was readily reduced. The child at first improved, but in about four hours symptoms of collapse appeared, and death supervened.

At the autopsy there was seen to be gangrene of the parts involved in the strangulation. The hernia was on the right side, and included a small part of the ileum, the cæcum, and the vermiform appendix. The case was particularly interesting from the fact that gangrene of the gut had occurred in a child in so short a time after the strangulation.

Dr. Frank H. Hopkins presented some sections of a

SUPERNUMERARY FINGER.

The specimen, from which the section was taken, was removed from a mulatto child, a female, at the age of three weeks. The fifth finger grew from the soft parts on the outer aspect of the first phalanx of the little finger of the right hand. It was attached by a slender pedicle, which allowed free movement. The pedicle was tied and the body snipped off. The finger thus removed was one centimetre long, half a centimetre thick, and had a well-developed nail and a joint. The microscope slide herewith presented showed a longitudinal section through the pedicle, through the cartilages, new bone, and joint. The points of interest were: 1. The intra-cartilaginous ossification in the distal extremity of the terminal phalanx. The specimen shows the new bone, new vessels tunnelling into the cartilage, osteoblasts, columnar arrangement of cartilage-cells in the region of the advancing vessels. 2. The joint in early life. 3. Vertical section of nail in its entire length. 4. Pacinian bodies.

The Society then went into executive session.

Stated Meeting, April 25, 1888.

W. P. Northrup, M.D., President, in the Chair.

Dr. H. M. Biggs presented, on behalf of a candidate, specimens of *Carcinoma of the Stomach* with secondary growths in other organs.

The President presented, on behalf of candidates, a specimen of *Lupus Vulgaris Nasi*, and one of *Fluctuating Mammæ in a boy* aged seven days. The glands contained milk.

Dr. Biggs reported from the Microscopical Committee that the specimen shown at the last meeting by Dr. Lewis Hall Sayre was one of round-cell sarcoma growing from the periosteum.

Dr. C. R. Hexamer presented a specimen of

ANEURISM INVOLVING THE THORACIC AND ABDOMINAL AORTA,

removed from the body of a man seventy-three years of age, who had entered St. Francis' Hospital a few days after the blizzard of March 12th, complaining only of exhaustion from exposure, and seeking rest for a few days to recuperate. He was remarkably robust-looking for his age, and was in good physical condition. He said he had not been sick a day for forty years. The heart action was very feeble, and a bruit was heard both anteriorly and posteriorly. One day, without any premonitory symptoms, the man suddenly had an attack of syncope, went into collapse, and died in about twenty minutes. At the autopsy an aneurism was found of the arch of the aorta, and another of very large size on the abdominal aorta. The latter filled one-half of the abdominal cavity, the sac being eight or nine inches in length by four inches in diameter. The interesting points were the large size of the sac, the double lesion, and absence of all symptoms pointing to the presence of aneurism.

Dr. Mary A. Dixon Jones presented a microscopical specimen of

SARCOMA OF THE CERVIX UTERI.

The specimen was presented not so much to demonstrate the sarcoma as to show that the cervical portion of the uterus was hyperplastic before the invasion of the sarcoma, and that the protoplasm of the sarcoma first invaded the newly formed fibrous connective tissue. This verified the assertion of Thomas Addis Emmet, that cervical lacerations may be the cause of, or invite, malignant growths.

Dr. Jones presented a second specimen, showing an

OVARIAN CYST AND CIRRHOTIC OVARY,

removed by operation from the body of a woman, twenty-two years of age, who had been sick for the last five years, during the whole of which time she said she had not had a well day or one free from pain. She had been under the care of several physicians, and apparently the trouble was an extreme retroversion of the uterus, the organ being so extremely sensitive that it resisted all efforts at replacement. By manual examination a large sensitive mass could be detected in front of the uterus and adherent. She was under treatment for some time in the Woman's Hospital of Brooklyn, but without obtaining any relief. Four days ago an abdominal section was made, and a growing ovarian cyst, three inches in diameter, was found in front of the uterus, and bound down by many adhesions. During removal it burst, and a straw-colored fluid escaped. The left ovary was atrophied and dragged far up on the left side, and ensheathed by firm adhesions.

Dr. Jones also presented some microscopical specimens, showing the uterine appendages in a case of

UTERINE MYOMA.

The right tube, measuring ten inches in length, was coiled upon itself and filled with bloody serum. The closed fimbriated extremity was four and three-fourths inches in circumference.

The muscles of the walls of the tube had almost entirely disappeared, being replaced by fibrous connective tissue. A few remnants of the muscle-fibres had become waxy, and these were breaking down into inflammatory corpuscles. The epithelia of the mucosa had entirely disappeared, no remnants of them were left; and there were only a few remains of the folds of the mucosa left, and these were entirely changed to fibrous connective tissue, almost cicatricial. There were many newly formed blood-vessels with thick walls, and the newly formed fibrous connective tissue was crowded with inflammatory corpuscles.

The left tube was five inches in length and filled with pus. Almost the entire muscular structure of this tube also had disappeared, or was changed to fibrous connective tissue, and this new tissue was crowded with inflammatory corpuscles which, in many places, formed abscesses. The few scattered bundles of smooth muscle left were in a state of intense inflammation and beginning ulceration.

Also, in the left tube, the epithelia of the mucosa were entirely destroyed, and the mucosa was crowded with inflammatory corpuscles. Only a few blunt remnants of the folds of the mucosa were left, and these were in a state of intense inflammation. Amid these thickly crowded inflammatory corpuscles were seen in every part coarse bundles of fibrous connective tissue, showing that the mucosa had previously been invaded by a plastic inflammation, of which, probably, there had been repeated attacks. Also in the mucosa, or in the previously formed tissue, there were seen many newly formed blood-vessels.

The ovaries also gave evidences of extensive changes from long-existing disease; only a vestige of normal ovarian structure was seen, nor could an ovum be found in either ovary. Though the pathological changes showed long-existing chronic disease, yet portions of the ovary were in a state of acute inflammation; thus it would be properly diagnosed

SUBACUTE OÖPHORITIS.

When it was remembered that the disease of the appendages had been existing a long time, most probably antedating the formation of the myoma, Dr. Jones thought that the question might fairly be raised whether the diseased appendages had not produced the myoma.

Dr. H. M. Biggs presented a number of specimens illustrating a series of aneurisms. The first was one of

ANEURISM OF THE ARCH OF THE AORTA,

situated at the junction of the transverse with the descending portion, removed from the body of a negro dying in the penitentiary. The man presented signs of lobar pneumonia, but had no symptoms suggesting an aneurism. He was suddenly taken with syncope while at stool, and died in a few minutes. At the autopsy an aneurism of the arch of the aorta was found, which had caused erosion of the vertebræ, and had ruptured into the œsophagus. The lesion in the left lung was a very striking one, and its exact nature had not yet been ascertained. There was a very distinct and sharply defined red and white mottling, which at first sight seemed to be caused by multiple lympho-sarcomata. The microscopical examination had not been completed, but it had gone far enough, however, to show that this was not the lesion.[1]

The President said that the gross appearances in the lung were similar to those seen in the lungs of children who had died of lobular pneumonia, especially when the disease occurred secondarily to diphtheria.

The second specimen was one of

DISSECTING ANEURISM OF THE AORTA.

In this, the starting-point for the separation of the coats of the aorta was in its first part, just above the valves, and the dissection had proceeded up over the arch, and then down, involving the entire length of the thoracic aorta, passing through the diaphragm, and terminating in the abdomen. The man had died suddenly. No history of the case was obtainable.

Dr. Biggs also presented a third specimen showing

MULTIPLE ANEURISM OF THE AORTA.

First, there was a dilatation of the aorta just above the valves. Then, upon the transverse portion of the arch, immediately before its termination in the descending portion, there was a saccular dilatation, and from this arose a second sac. Finally, there was another aneurism on the descending aorta. The woman from whom the specimen was taken was an inmate of the workhouse, and had died of pneumonia. During life a small pulsating tumor had been noticed, but there were no other signs indicative of the condition found after death.

---

[1] At a meeting of the Society, held on May 23d, Dr. Biggs reported that he had completed the microscopical examination of the lung, and had found that the peculiar mottling was caused by a combined lobar and broncho-pneumonia. The red color was due to the lobar pneumonia, and the white areas showing through the red were the infiltrated walls of the bronchi.

Dr. H. P. Loomis presented a specimen of

ABSCESS OF THE LIVER, WITH PERFORATION OF THE DIAPHRAGM,

sudden death occurring under ether. The patient, a man about thirty-eight years of age, came under observation on March 2d. His family history was good. He acknowledged having had syphilis, and said he was accustomed to go on periodical sprees. He had enjoyed perfect health up to four years ago, at which time, during a period of eight months, while residing in Kansas City, he had severe attacks of malarial fever, accompanied by diarrhœa and bloody stools. After leaving Kansas City he recovered his accustomed health until a year ago, when, after taking cold, he was seized with an attack of dysentery. The patient gradually recovered from his dysentery, but found now that any indiscretion in eating or in the use of stimulants would bring back a diarrhœa, accompanied by tenesmus and the passage of blood. Last Christmas the patient went on a spree, and after that he was much worse, having on an average as many as seven bloody movements daily, accompanied by tenesmus. Lately he complained at times of intense pain over the region of the liver, and was slightly jaundiced.

On examination all the organs were found in apparently healthy condition, with the exception of the liver, which was enlarged, the left lobe projecting about two inches below the free border of the ribs. The organ was tender on pressure. The patient's general condition improved during March, although the dysenteric movements continued, and percussion showed that the liver was increasing in size. He had no fever nor chills at any time. On April 2d the patient began to grow worse, the signs of subacute pleurisy on the right side developed, and the dysenteric movements increased up to about twelve a day. On April 6th the fluid in the right pleural cavity had increased to such an extent that an aspirating needle was introduced at the level of the sixth rib, two and a half inches from the median line, and twenty ounces of amber-colored serum, containing some flocculi of lymph, were withdrawn.

A few days after, when the needle of a hypodermic syringe was introduced one inch below and one and a half inch to the outer side of the point where the aspirating needle was previously introduced, a reddish purulent fluid was withdrawn, which, on microscopical examination, presented the appearance of fluid from an abscess of the liver. About two inches above the point whence the purulent fluid was withdrawn, a needle was introduced and clear serum was obtained. The case was diagnosed "an abscess of the liver," and an exploratory opening was advised.

On April 14th the patient was placed on the operating table and ether administered. Suddenly he became cyanosed and stopped breathing. All means to restore him failed, and he died without a cut being made.

Autopsy, made thirty-six hours after death: The right pleural cavity, for its upper three-fourths, was filled with serum in which were shreds of fibrin. At the lower fourth was a pus-cavity, enclosed by adhesions, which communicated, by an opening in the diaphragm close to the ribs, with an abscess of the liver. The opening in the diaphragm would barely admit the index-finger.

The abscess of the liver was a small superficial abscess, situated in the back portion of the right lobe, four and a half by four inches in diameter, and about two inches in depth. The weight of the liver was six pounds, and its structure was normal. The left lung was normal. The right lung was compressed against the vertebral column by the fluid in the right pleural cavity.

The heart weighed 250 grammes, and showed marked dilatation of the left ventricle, with thinning of the walls. The thickest part of the right ventricle was hardly half an inch thick. There was no valvular lesion, but quite extensive atheroma of the aorta and of the coronary arteries. A microscopical examination of the cardiac muscle showed very extensive interstitial myocarditis.

The other organs were normal, with the exception of eight or ten dysenteric ulcers involving the cæcum.

The two interesting points of the case were: 1st, the peculiar encysted condition of the pus from the abscess after it had perforated the diaphragm, together with the serum in the upper portion of the pleural cavity; 2d, the sudden death from only a few whiffs of the ether, due, no doubt, to the extensive myocarditis which was not recognized during life, although the patient had been examined by some of the best diagnosticians in the city.

The President reported the case of a young man who had a history of gall-stones and an affection of the liver. He was expectorating a very foul-smelling, purulent fluid. Paracentesis was performed without ether, as it was feared that the other lung might become infected by the passage into it of this purulent matter during narcosis. The chest being opened, a sound was passed down through the diaphragm into the liver. The patient was at death's door for three days, but then began to rally, and is now a strong and healthy man.

Dr. H. J. Boldt presented a specimen of

EXTRA-UTERINE PREGNANCY.

The patient was referred to him, on account of a tumor in the abdomen, by Dr. Krollpfeiffer. She had recently passed through an attack of acute peritonitis, and, at the time Dr. Boldt first saw her, had a temperature of 102° F. in the axilla, and presented the appearance of one suffering from pyæmia. The tumor extended as high as the umbilicus, and the first thought was that it was a gravid uterus, especially as the menses had stopped seven months before. Examination, however, showed that the uterus was empty, and that the tumor lay to the left of this organ. The case was then diagnosticated to be one of abdominal pregnancy, and an operation was advised and agreed to by the patient. The operation was one of unusual difficulty, as the intestines were very strongly adherent to the sac. The right tube could be traced, but the corresponding ovary could nowhere be found. The walls of the sac were very thick, and an attempt was made to suture them to the abdominal wound; but this was only partially successful. The patient did well for about twenty-four hours, but then began to sink, and died in a few days. The fœtus had died at about the sixth month.

Dr. Frank Ferguson presented a specimen showing an

ANEURISM OF THE ASCENDING PORTION OF THE ARCH OF THE AORTA OPENING INTO THE PULMONARY ARTERY.

The specimen was taken from the body of a man, forty-five years of age, who was admitted to St. Luke's Hospital, in the service of Dr. F. P. Kinnicutt, on February 17, 1888.

He entered the hospital at 5 P.M., suffering from extreme dyspnœa. His face and hands were cyanotic. The heart action was very rapid, and there were murmurs which were masked by the presence of numerous moist sounds over the chest during respiration. He could not lie down, and suffered intensely from dyspnœa. He became more and more cyanotic, his pulse was imperceptible at the wrist, and after a slight exertion he suddenly died.

The *autopsy* was made twelve hours after death. The heart was found increased in size; the ventricles were dilated, and there was fat in the muscular tissue. The aortic and mitral valves were competent. There was an aneurism as large as an ordinary hen's egg in the anterior wall of the ascending portion of the aortic arch. There was found a rupture of the wall of the sac and an erosion of the posterior wall of the pulmonary artery, establishing a free communication between the aorta and the pulmonary artery by a circular orifice one-half inch in diameter. This orifice was situated just above the pulmonary valve. One of the cusps of the pulmonary valve was adherent to the wall of the artery for a distance of one-fourth of an inch, which must have rendered the valve incompetent.

A second specimen was also one of

ANEURISM OF THE ARCH OF THE AORTA,

taken from the body of a man, fifty-three years of age, who was admitted to the New York Hospital, in the service of Dr. E. L. Partridge, on April 5, 1888. Nine months previous to his admission he had malarial fever, and eight months later he had a slight attack of rheumatism.

For the past few months he had had muscæ volitantes, headache, dyspnœa on exertion, slight palpitation, morning nausea, and vomiting. During the three weeks preceding his admission into the hospital he passed a diminished quantity of urine of high color, but showed no other nephritic symptoms.

He had a well-marked alcoholic habit. For some years he had been subject to a slight cough, which. during the five months preceding his residence in the hospital, was accompanied by a whitish expectoration. During the last three or four weeks of this time his abdomen became distended, the distention increasing his dyspnœa. On admission his appetite was poor, and his bowels were constipated, but his chief complaints were weakness, cough, distention of the abdomen, and dyspnœa.

Percussion revealed dulness from the second rib, on the left side, to the left apex, but below the second rib the percussion note was normal. The expiration was prolonged and low-pitched, and there were sonorous rhonchi on inspiration, and on expiration many sibilant râles and sonorous rhonchi, with an occasional coarse, moist râle.

Posteriorly, over both sides, the physical signs were similar, but more marked in degree. The superficial cardiac area could not be determined, owing to pulmonary resonance. The aortic sounds were normal. At the apex the cardiac sounds could not be heard. The pulse was small and wiry, and the legs were markedly œdematous.

His case was diagnosticated as chronic diffuse nephritis and cirrhosis of the liver. Under appropriate treatment he improved considerably until April 15th, when he felt pain in his left chest, his respiration became gasping, and he suddenly died. The autopsy revealed 3,000 c.c. of pure blood in the left pleural cavity. There was an aneurism of the transverse portion of the arch of the aorta, ovoidal in shape, 14 ctm. in length and 10 ctm. in diameter. The sac was almost filled with laminated fibrine. The orifice of communication with the aorta was oval in shape, and 5 by 4 ctm. in size. The sac had ruptured on the left side, giving rise to the escape of the blood into the left pleural cavity by a slit-like opening, 2 ctm. in length. The aorta was very atheromatous and dilated. The great vessels arising from the arch were to the left of the opening in the aortic wall, and the blood in the aorta entered freely into these vessels. The left subclavian vein contained a small thrombus. The valves of the heart seemed competent, and the heart was normal in size, while the muscular tissue was anæmic. The kidneys were found in a state of chronic diffuse nephritis. There was much fibrous tissue in the liver; the lungs were normally supplied with blood and well distended with air, and they covered in the aneurism completely. The heart was displaced downward slightly. The œsophagus and trachea were apparently free from pressure.

Dr. Ferguson then presented another specimen showing an

ANEURISM OF THE THORACIC AORTA OPENING INTO THE ŒSOPHAGUS.

It was taken from the body of a man, fifty years of age, who was admitted to the New York Hospital, under the care of Dr. George L. Peabody, on September 22, 1887. Three years previous to admission he began to have pain in the left shoulder, which gradually grew worse, and one year later he developed a cough, accompanied by a white expectoration. Ten days before his admission he suffered from dyspnœa and dysphagia. His appetite was poor, and the bowels were constipated, but his pain was his chief complaint.

The cardiac area was found diminished in extent, and the cardiac sounds were faint, but otherwise normal. The pulse was of fair tension, and the arteries were tortuous and atheromatous. He was poorly nourished. There was no œdema. On the back, occupying the inter-scapular region, and extending to the left side, there was a large tumor measuring twelve inches in vertical diameter and eight inches horizontally. Over this swelling expansile pulsation was felt, but no murmur could be heard. Over the entire extent of the swelling there was flatness. During his residence in the hospital he suffered considerable pain, which was always, however, relieved by morphine. About ten minutes before he died he suffered intensely from dyspnœa, and had also a severe attack of coughing and vomiting of blood.

At the autopsy there was found a large aneurism, occupying the posterior half of the left pleural cavity, above the seventh rib, and extending four inches beyond the median line on the right side.

The aneurism was filled with laminated fibrine and partially coagulated blood. When the sac was removed, with a portion of the vertebral column, it was found to measure nine inches transversely and seven and one-half vertically. The third and the seventh ribs were partially eroded, and those between them completely severed. The sac communicated with the aorta by an opening one inch in diameter, and located three inches below the origin of the left subclavian artery. On the median line, in the posterior wall of the œsophagus, on a level with the bifurcation of the trachea, was a small opening through which blood escaped from the aneurismal sac. This opening was one-fourth of an inch in diameter. Several of the dorsal vertebræ were very deeply eroded. The heart was normal in size, and the valves were competent.

Dr. West Roosevelt presented two specimens of

SARCOMA OF THE MEDIASTINUM.

Case I.—Anne S——, aged thirty-eight years, was admitted to Roosevelt Hospital on July 26, 1883. Mother died of phthisis. Seems to have had no important sickness till last March. Then had "pleurisy" lasting three weeks. About April 15th returned to work. Soon had dyspnœa on exertion, cough in the morning, with whitish sputa; occasional pain in back. Six weeks ago a swelling appeared in the right arm and wrist, and soon spread up the arm and involved the shoulders, head, and neck. During the last few weeks the patient had suffered from darting præcordial pains. The urine was acid, sp. gr. 1.027, contained a trace of albumin, but no casts—there were abundant urates. Diagnosis: Signs of pressure on the trachea or bronchi, most on right side. May have aneurism pressing on cava descendens and trachea. Œdema due to thrombosis. Both radials are very feeble. right possibly a little more than the left, but no marked difference. Sibilant rhonchus takes the place of the respiratory murmur on the right side in front, on the left side front exaggerated respiratory murmur. Marked dulness in the right chest in front and behind. Absent vocal fremitus on right side. No heart murmurs.

Several severe attacks of dyspnœa, without spasm of glottis, occurred on August 14th, and the following day the patient died.

Autopsy, August 16, 1883.—The heart was of normal size. Ante-mortem clot in right ventricle and auricle, and running into pulmonary artery. In the thorax was a new growth occupying the entire mediastinal space, surrounding the main bronchi of the right lung, causing almost complete obliteration of the superior vena cava, in which was a firm thrombus. The tumor extended upward in front of the trachea as far as the thyroid, sending projections upon each side of the larynx. It was adherent to the last cervical and first dorsal vertebra, and extended forward to the first rib, to which it adhered on the right side. It extended downward to about an inch above the diaphragm. A large part seemed to be composed of enlarged and adherent lymphatic glands. The tumor on section was white and pinkish-white in different places. Some portions contained a good deal of "cancer juice" and some were quite dry. The jugular, innominate, and subclavian veins on the right side all contained thrombi, where they entered the tumor. The walls of the jugular on the right were completely infiltrated, and the lumen of the vessel was almost obliterated.

The tumor, under the microscope, was found to be formed of a fibrous tissue stroma, which had embedded in it large and small round cells. It was very vascular. The lymphatic glands in the neighborhood were enfiltrated with similar growth. The walls of the bronchi and of the large veins near the tumor were similarly infiltrated.

Case II.—William H——, aged eleven years, admitted August 25, 1883. The patient was moribund on admission. Child had been sick for only two months. He had œdema of the face and a cough. About six weeks ago a swelling as large as a goose egg appeared in the axilla. It was not painful and soon disappeared. Dyspnœa had been present for six weeks, worse at night. The child had lost flesh, especially during the last two weeks. On admission there was marked orthopnœa and considerable œdema of the upper extremities was noted. The patient died the day following admission.

Autopsy.—On opening the thorax a new growth was seen occupying the entire mediastinum, sending a process up along the left of the trachea as far as the larynx. It compressed the trachea to about one-half its normal size, and compressed and almost obliterated the descending cava and right jugular and innominate veins, also the right carotid and subclavian arteries, and slightly the transverse arch of the aorta. The left carotid and subclavian veins were also compressed. The left jugular and innominate and subclavian veins could not be found. The growth infiltrated the walls of these vessels. The bronchi of the left lung, for a distance of about an inch and a half from their entrance into the lung, were infiltrated and compressed. The upper lobe of the left lung was in great part converted into tumor-tissue, with a few masses of compressed lung-substance between. Numerous patches of gray lobular pneumonia were seen in the remaining portion of this lung. The upper lobe adhered throughout to the chest-wall. The left chest was nearly full of clear serum, but there was none in the right. Pericardium was distended with liquid blood. The valves, as well as the myocardium, seemed normal. The tumor resembled the other in microscopic structures.

Tumors of the mediastinum are rather rare, and they are of interest on account of this comparative rarity. In the first case the diagnosis became pretty clear. The physical signs indicating pressure on a large bronchus, and the symptoms pointing to the obstructed superior cava, were very pronounced. From the histological structure of the neoplasms it seems probable that they had their origin in the bronchial or mediastinal glands.

The Society then went into executive session.

Small and Pleasant Doses.—"Why," asks the editor of the *Kansas City Medical Index*, "give nasty tincture of digitalis when a triturate of digitaline, tasteless, will accomplish the same end? Why give castor-oil or Epsom salts (ye gods! no wonder children cry! Doctor, did you ever take a tablespoonful of castor-oil?) when a fourth or half grain of the officinal triturate of elaterine, perfectly tasteless in a little sugar of milk, will cause free and painless evacuations? Why give bromide of potassium in simple water—nauseous, disagreeable—when by the aid of modern pharmacy its taste may be disguised, as in the elixir of bromide of potassium? Why give large doses of quinine to control the fever following indiscretions in eating, so often met in children, when a light purge followed by a half-drop of aconite every hour or two in water will attain the same result in less time?"
